As announced in the SUPPLEMENT of April 8th, page 101, representatives of the British Medical Association and of the Society of Medical Officers of Health met a special sub-committee of the Town Hall Committee of the Manchester Corporation on April 7th to consider the objections of the two medical bodies to the proposed appointment of a medical officer of health for Manchester at a salary of £1,500 a year. All the representatives mentioned in the Current Note last week were present, except that Dr. R. A. Lyster took the place of Dr. G. F. Buchan as a representative of the Society of Medical Officers of Health. The medical representatives met in the forenoon to consider the line of action to be taken. In addition to the four representatives of the Manchester Division, Alderman Chapman (Chairman), Dr. R. G. McGowan (Secretary), Dr. T. A. Goodfellow, and Sir William Milligan, there also attended Councillor Dr. R. N. Marshall and Councillor Dr. C. H. S. Redmond. Afterwards all the medical representatives were most hospitably entertained to luncheon by the Town Hall Committee, and there were present Alderman Derwent Simpson, chairman of the committee, Sir Charles Behrens, vice-chairman, the Deputy Lord Mayor, Alderman Kay, with other members of the committee. After luncheon Alderman Simpson gave a cordial welcome to the medical representatives, and expressed a strong hope that the deliberations afterwards would be productive of a result which should be satisfactory both to the profession and to the city of Manchester. Dr. Bolam, on behalf of the British Medical Association, and Dr. Howarth, on behalf of the Society of Medical Officers of Health, expressed the thanks of the visitors for the hospitality that had been shown them, and promised that no effort would be wanting on their part to bring the dispute to an early, satisfactory, and friendly termination.

Later a conference took place at which the whole matter was thoroughly discussed for about two and a half hours, and finally the representatives of the medical profession laid certain proposals before the subcommittee, which Alderman Simpson promised to place before his committee, and through it before the Council.

Glasgow Meeting: Hotel Accommodation.

While Glasgow is a most hospitable city, it is singularly ill equipped with hotels. This deficiency, as one may easily understand, is the result of the extraordinary industrial development of the city — few authorities are known to have advocated Glasgow as a health or pleasure resort. There is a considerable number of small hotels which cater almost exclusively for the commercial class, and which have seldom an empty room. The managers of these hotels are really unable to reserve or promise rooms for the end of July. The larger hotels are practically only the "railway" hotels.

At the Clyde resorts and the more accessible inland health centres there are some very good hotels and hydropathies. The availability of these is to some extent impaired by the fact that the latter part of July contains the city of Glasgow annual holiday week, at which time these institutions will contain a large number of migrated Glasgow citizens.

While no ultimate difficulty is anticipated in housing the members who will attend the Annual Meeting in July, it has not been found possible at this stage to publish an adequate list of private lodgings. Such a list will appear in May. As a preliminary measure a list is published below of the most convenient hotels in the city itself, with their charges. As fairly complete arrangements have been made for the pleasant absorption of the hours of the visitors during the days and evenings, prices have been quoted for accommodation and breakfast only. In all cases, luncheons are advertised at 3s. 6d. to 4s. 6d., and dinners from 6s. to 7s. 6d. Intending visitors are strongly recommended to engage their hotel accommodation at the earliest possible moment.

	Bedroom and breakfast.
Central Station Hotel (Caledonian Railway) ...	12/- to 15/6
North British Station Hotel ...	12/3 to 14/-
St. Enoch Station (G. and S.W. Railway) ...	From 11/-
Grand Hotel, Charing Cross ...	16/- to 10/5
Green's Private Hotel, Woodlands Terrace ...	10/6
Clarendon Private Hotel, Clarendon Terrace ...	15/5
Mor's Private Hotel, India Street ...	From 9/6
Bath Hotel, 352, Bath Street ...	8/6

In our issue of April 22nd it is hoped to publish a list of the hotels and hydropathies in the immediate vicinity, with a note of their distances from the city and their probable train services. The Chairman of the Hotels and Lodgings Committee is Professor J. M. Munro Kerr, and the Honorary Secretary, Dr. James Hendry, 4, Clifton Place, Glasgow, W. (Telephone, Charing 1260.)

Insurance Pharmacy Terms for 1922.

The *Pharmaceutical Journal* of April 8th reproduces a letter from the Ministry of Health to the Retail Pharmacists' Union in regard to the terms of service for chemists supplying drugs and appliances to insured persons. Our contemporary describes this as an "ultimatum to panel chemists," and anticipates that it will create acute disappointment and intense dissatisfaction. The letter reminds the committee of the union that the various increases in the dispensing fees were granted mainly on account of the abnormal conditions arising from the war. In view of the rapid fall in the cost of living which has taken place since the last revision of the scale it appears to the Minister that the proposed reduction in the remuneration of insurance pharmacists is fully warranted by the altered economic position, and that it is not incommensurate with the reductions which have been made in the remuneration of insurance medical practitioners and generally in the public and municipal services. He maintains his opinion that a reduction of 1d. on each item in the dispensing scale is fully justified. On and after May 1st, 1922, the rate for compound liquid medicaments (excluding preparations specified in the table of drug prices and proprietary preparations) will be reduced to 5d. per

prescription, and the rates in respect of the remaining items in the dispensing fee scale will, in like manner, be reduced by 1d. per prescription. Where the prescription directs that the medicaments shall be supplied in two or more containers, a special charge of 2d. for each additional container may be allowed. Commenting on this letter, the *Pharmaceutical Journal* observes that "if panel chemists refuse to accept the new terms their only course is an organized withdrawal from the service. But it is questionable, having regard to all the circumstances, whether this is a favourable time to all recourse to that drastic alternative."

Expenditure and Income Statistics.

The attention of the medical profession is again drawn to the offer of a gratuitous copy of a model account book to any practitioner undertaking to forward the information entered therein for the confidential use of the Insurance Acts Committee. There can be no doubt that all information under this head ought to be in the possession of the central negotiating body for insurance practitioners (the Insurance Acts Committee), for use at the time of the revision, at the end of 1923, of the present bargain with respect to the insurance capitation fee. Inquiries should be addressed to the Medical Secretary, 429, Strand, W.C.2.

Statistics of Insurance Work.

Insurance practitioners are reminded of the necessity for the Insurance Acts Committee to be supplied with statistics of insurance work done in 1921. Information under the following heads should be sent to the Medical Secretary, 429, Strand, W.C.2.

Name.	Insurance Address.	No. of Insured Persons on List.	No. of Insured Persons Attended during 1921—that is, No. of Patients.	No. of Consultations.	No. of Visits.

Association Notices.

TABLE OF DATES.

- April 26, Wed. Council Meeting, 429, Strand, at 10 a.m.
 April 29, Sat. Last day for receipt at Head Office of Independent Motions for Annual Representative Meeting Agenda, as to policy, Articles, or By-laws (By-law 40).
 May 6, Sat. Annual Report of Council appears in SUPPLEMENT.
 May 8, Mon. Last day for receipt at Head Office of Nominations, by a Division or not less than 3 Members, for election of 24 Members of Council by grouped Home Branches for 1922-23.
 May 13, Sat. Publication in SUPPLEMENT of list of nominations for election of 24 Members of Council by grouped Home Branches for 1922-23.
 May 27, Sat. Voting papers for election of 24 Members of Council by grouped Home Branches posted from Head Office to Members of groups where there are contests.
 June 3, Sat. Last day for receipt at Head Office of voting papers for election of 24 Members of Council by grouped Home Branches (where there are contests).
 June 10, Sat. Publication in SUPPLEMENT of results of Council elections by grouped Home Branches.
 June 14, Wed. Nomination papers available, at Head Office, for election of 12 Members of Council by grouped Home Representatives.
 June 23, Fri. Council Meeting, 429, Strand, at 10 a.m.
 June 24, Sat. Last day for election of Representatives and Deputy Representatives.
 June 30, Fri. Supplementary Report of Council appears in SUPPLEMENT.
 July 7, Fri. Last day for receipt at Head Office of notification of election of Representatives and Deputy Representatives.
 July 21, Fri. Last day for receipt at Head Office of Amendments and Riders for Annual Representative Meeting Agenda.
 Annual Representative Meeting, Glasgow, 10 a.m.
 Nominations for election of 12 Members of Council by grouped Representatives to be received at Annual Representative Meeting, Glasgow) by this date.

ALFRED COX, Medical Secretary.

BRANCH AND DIVISION MEETINGS. TO BE HELD

EAST YORK AND NORTH LINCOLN BRANCH: EAST YORK DIVISION.—The annual dinner of the Division will be held in the Royal Station Hotel, Hull, on Friday, April 21st, at 8 p.m. prompt. The Chairman's guest will be Mr. C. A. R. Nitch, M.S., F.R.C.S., Surgeon, St. Thomas's Hospital. Tickets, 12s. 6d. each, may be obtained from the Secretary or from any member of the Executive Committee.

EDINBURGH BRANCH: SOUTH-EASTERN COUNTIES DIVISION.—The annual meeting of the South-Eastern Counties Division will be held in the Railway Hotel, Newtown St. Boswells, at 3.15 p.m., on Wednesday, May 3rd. Business: Election of officers; annual report of Executive Committee; instructions to Representative, particularly as regards hospital question; Hawick Maternity Centre, resolution under Ethical By-laws as to professional conduct; any other competent business. A meeting of the Executive Committee will be held at 3 p.m. at the same place on the same day.

METROPOLITAN COUNTIES BRANCH: CAMBERWELL DIVISION.—The annual general meeting of the Camberwell Division will be held at the Camberwell Infirmary, Brunswick Square, at 9 p.m., on Friday, April 28th, for instruction of the representatives. The report of the Council on the organization of voluntary hospitals (SUPPLEMENT, February 25th) will be discussed; also the question of professional secrecy and other important matters. A further meeting of the Division will be held on Wednesday, May 17th, at the Camberwell Infirmary, at 9 p.m., when a lecture on "The diagnosis of pyorrhoea alveolaris in its relation to general disease" (with lantern) will be given by Mr. F. N. Doubleday, M.R.C.S., L.D.S. (Guy's Hospital).

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.—The annual meeting of the Willesden Division will be held at St. Andrew's Parish Hall (Institute behind Church), High Road, Willesden Green, on Tuesday, April 18th, at 8.30 p.m. Agenda: Election of officers, Representatives on Branch Council. Executive and Ethical Committees; receive annual report; consider hospital policy of the British Medical Association; reduction of fees for members of pension boards; matters arising out of municipal election.

NORFOLK BRANCH.—A meeting of the Norfolk Branch will be held at the Norfolk and Norwich Hospital, Norwich, on Thursday, April 27th, at 3 p.m., when an address will be given by the Medical Secretary.

NORTH OF ENGLAND BRANCH: DARLINGTON DIVISION.—A meeting of the Darlington Division will be held at Greenbank Hospital on Thursday, April 20th, at 8.30 p.m., when Mr. F. C. Pybus, M.S., F.R.C.S., will give an address on surgery of childhood.

NORTH OF ENGLAND BRANCH: STOCKTON DIVISION.—A scientific meeting of the Stockton Division will be held in the Stockton and Thornaby Hospital on Friday, April 21st, at 8.30 p.m., when Mr. J. Hamilton Barclay, M.S., F.R.C.S. (Newcastle-on-Tyne) will give a lecture on "Acute intestinal obstruction." A large attendance is hoped for, and members of the neighbouring Divisions are invited and will be cordially welcomed.

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—A meeting of the Sunderland Division will be held at 48, John Street, on Tuesday, April 25th, at 8.15 p.m. Business: To consider the standing resolutions of the Division and the suggested changes recommended by the special subcommittee and approved of by the Executive Committee for adoption by the Division.

- Standing Resolutions.**
1. The minimum fee, for midwifery cases shall be two guineas. This resolution need not apply to colliery cases.
 2. One shilling per fortnight shall be the minimum rate for family club practices. This shall include all members of the family under 15 years of age.
 3. One guinea shall be the minimum fee for making a report in workmen's compensation cases. The resident staff of the charitable institution shall only supply such reports with the consent of the honorary medical officer in charge of the case.
 4. Three shillings and sixpence shall be the minimum fee for vaccination.
 5. No member shall act as medical officer to any society or association which administers medical benefits.
 6. Certificates for insured persons to obtain their benefits under National Insurance Acts shall be given free. All other certificates shall be charged at least 1s. each.
 7. Medical certificates shall not be supplied in the case of children attending elementary schools.
 8. Candidates for entrance to approved societies or other similar bodies shall be charged a fee of not less than 3s. 6d. for examination and the certificate.
 9. No fee less than two guineas to be charged in any midwifery case.
 10. The midwifery fee includes subsequent attendance for not more than fourteen days.
 11. Where a house in the midwifery tariff list is tenanted a reduction may be made in the fees.

SOUTH-WESTERN BRANCH. Other business.
 Branch will be held at Barnstaple on Thursday, April 20th. Members desirous of bringing forward cases or specimens are requested to notify Mr. F. A. Roper, Honorary Secretary, by April 10th.

SURREY BRANCH: CROYDON DIVISION.—The annual general meeting of the Croydon Division will be held at the Croydon General Hospital on Wednesday, April 19th, at 3.30 p.m. Agenda: Report and balance sheet; election of officers; other business. After the general meeting a clinical meeting will take place, with

Dr. Genge in the chair. The exhibits will include medical and surgical cases, specimens, models, radiograms, drawings, photographs, and instruments. Members willing to exhibit are requested to inform the Honorary Secretary not later than April 15th. The annual dinner will be held at the Greyhound Hotel, Croydon, on Tuesday, April 25th, at 8 p.m. Price 7s. 6d. exclusive of wines. It is hoped that all members who possibly can will attend this dinner and thus ensure its success. Early intimation to the Honorary Secretary, Dr. C. G. C. Sendamore, 117, Whitehorse Road, Croydon, will greatly facilitate the arrangements.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.—The spring meeting of the Worcestershire and Herefordshire Branch will be held at Great Malvern Hospital on Thursday, April 27th, at 3 p.m., when a British Medical Association lecture will be given by Professor Murray (Manchester) on "Hypert thyroidism and its treatment."

Meetings of Branches and Divisions.

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.

A MEETING of the Kensington Division was held in Kensington Town Hall on April 5th, when Dr. WALTER E. FRY was in the chair.

On the motion of Dr. W. E. Fry, a vote of congratulation was unanimously accorded to the Willesden Division on their successful fight with their borough council.

After discussion the following resolution was, on the motion of Mr. HOWARD STAFFORD, seconded by Dr. H. A. GILLESPIE, passed unanimously:

"That the Kensington Division strongly disapprove of the proposed reduction in the sessional fees paid to chairmen and members of the Ministry of Pensions Medical Boards, and consider that they should remain as at present."

The CHAIRMAN introduced a discussion on the "Report on the Organization of Voluntary Hospitals" (SUPPLEMENT, BRITISH MEDICAL JOURNAL, February 25th, 1922). The report was gone through section by section, and was generally approved. No amendments were submitted.

Dr. CHARLES BUTTAR was unanimously nominated for a seat on the Council.

METROPOLITAN COUNTIES BRANCH: WEST HERTFORDSHIRE DIVISION.

At a meeting of the West Hertfordshire Division held on April 5th it was decided to support at the Annual Representative Meeting in Glasgow, the policy of the Association as outlined in report on the organization of voluntary hospitals. Dr. Hall (Watford) was appointed the Representative of the Division.

METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.

A MEETING of members and non-members was held at St. Andrew's Parish Hall, Willesden Green, N.W., on March 21st.

The HONORARY SECRETARY reported correspondence and further interview with the President of the local branch of the Red Cross Society and the County Organizer with respect to the proposed establishment of a V.A.D. clinic and orthopaedic centre for Harlesden, and that he had suggested to the officials of the society that they should visit the V.A.D. clinic at Kensington. The communication, dated March 1st, 1922, from the Willesden U.D.C. (printed in the SUPPLEMENT of March 11th) was also reported. A draft reply was then considered, and after discussion it was resolved that this be forwarded to the Willesden Town Council, and that copies thereof be sent to the head office and the lay press.

In reply to a suggestion by the Willesden Labour Party for a public debate on the administration of the Public Health Acts in Willesden, the Honorary Secretary was instructed to state that the Division was of opinion that no useful purpose would be served by a public debate, but that it was always ready to meet representatives of the Labour Party on any health matter.

Dr. W. Paterson and Dr. Scott were appointed Representative and Deputy Representative respectively for the Annual Representative Meeting at Glasgow. Further consideration of the hospital policy of the Association as contained in the SUPPLEMENT of February 25th was postponed until the next meeting.

NORTH OF ENGLAND BRANCH: CLEVELAND DIVISION.

A BUSINESS meeting of the Cleveland Division was held at Middlesbrough on March 17th. Some discussion took place on the request for subscriptions to the Medical Representation in Parliament Fund, and the following resolution was carried *unm. con.*:

"That, in view of the great importance of public health in its national sense, as recognized by the recent establishment of a Ministry of Health, this Division approves of the principle of medical representation in Parliament, and recommends the financial support of medical candidates through this fund."

It was decided to take no divisional action on the request for subscriptions to the Wood-Hill Fund, but to leave the matter to the inclination of members privately. Discussion was then directed to the report on voluntary hospital organization. A number of amendments were agreed to, and the meeting adjourned owing to the lateness of the hour. The discussion was renewed on March 25th, when the remainder of the report was carefully considered, and certain amendments were ordered to be sent up to the Council.

At a meeting of the Division, held in the North Riding Infirmary on March 30th, under the presidency of Dr. W. S. DICKIE, chairman of the Division, Dr. WELLS PATTERSON (Newcastle-on-Tyne)

gave an interesting address on the endocrine glands and their inter-relationship. There was a very large attendance, including several members from the neighbouring Stockton Division. Dr. Patterson, in his address, dealt with each gland in turn and then with their various combinations. The discussion was opened by the CHAIRMAN, followed by Drs. HOWELL, INESTER, HENRY, WILLIAMS, BROWNLEE, and others. Dr. PATTERSON, in his reply, dealt with the points raised and questions asked. At the close of the meeting a hearty vote of thanks was, on the motion of Dr. DICKIE, accorded Dr. Patterson for his most interesting address.

NORTH OF ENGLAND BRANCH: STOCKTON DIVISION.

Two meetings of the Stockton Division were held on March 31st and April 7th, when the Council's Report on Hospital Policy was discussed. The greater part of the report was agreed to, but several amendments were suggested. Paragraph 33 was not agreed to. The report was considered on broad lines, but local conditions obtaining were considered in particular.

SOUTH MIDLAND BRANCH: NORTHAMPTONSHIRE DIVISION.

A MEETING of the Northamptonshire Division was held on March 29th. Dr. D. G. Greenfield (Rushden) was elected representative and Dr. D. Stone (Northampton), deputy representative in the Representative Body. The Report of the Council on voluntary hospitals was discussed, and a number of amendments suggested. The rest of the report was agreed to unless found to be counter to those amendments. The meeting, which was overwhelmingly composed of general practitioners, appeared to be strongly of opinion that tariff patients should pay the full cost of maintenance and treatment, and that no deduction should be made for staff funds in other instances.

SURREY BRANCH: CROYDON DIVISION.

A MEETING of the Croydon Division was held at the General Hospital on March 21st, when Mr. G. E. NEWBY, C.B.E., F.R.C.S., was in the chair. An address was given by Mr. F. T. CLEMENSON, M.Ch., F.R.C.S., on nasal obstruction in children. This was followed by a discussion in which the CHAIRMAN, Drs. CORNELL, RICHARDS, REDFERN, PINKERTON, PARTIDGE, and HAMMOND took part. Mr. Clemenston was heartily thanked for his address.

The winter session will close with a clinical meeting after the annual meeting on Wednesday, April 19th, and a dinner on Tuesday, April 25th.

Since October, monthly meetings have been held, and addresses have been given on various subjects of interest to the general practitioner. The result of these meetings have more than realized the expectation of the Committee and they will endeavour to arrange similar meetings next year. Each meeting has been well attended and has caused interest and discussion.

YORKSHIRE BRANCH: BRADFORD DIVISION.

THE annual dinner of the Bradford Division of the British Medical Association was held on March 30th, when ninety-six guests sat down to dinner, with Dr. T. JASON WOON in the chair. The health of the guests was proposed by the CHAIRMAN, and replied to by Archdeacon STANTON JONES, and by Mr. J. G. HUTCHINSON, the city coroner. The toast of the Bradford Division of the British Medical Association was proposed by the LORD MAYOR OF BRADFORD, and Dr. MANSELL replied.

Correspondence.

The Ministry of Health and the Friendly Societies.

SIR,—There is some talk of the Friendly Societies "having the right to be represented in any future negotiations with the medical profession" on the ground that they will contribute more towards medical benefit.

I deny that right. The approved societies do not pay one penny for medical benefit which they have not received from the public. It may be true that the societies will make less profit under the new arrangements, but that does not give them any "right" to dictate to the Ministry of Health.

What is the use of the nation having a Ministry of Health if one section of the public—for its own financial benefit—is to dictate how it, the Ministry, shall conduct its business? After all, the Friendly Societies are only the collectors of the public's insurance money.

The Insurance Act is a national one, not the property of a few companies, and so it must be administered entirely by the nation's representative, the Minister of Public Health. The army is a national one: I have yet to learn that the various regiments in it dictate to the Minister of State for War and tell him how to conduct the business the nation has placed in his hands.

The approved societies should have the right with the British Medical Association and other bodies to lay their views before the Ministry of Health, but they have no right or justification to be connected with the Ministry in an official capacity; they are servants only of that Ministry.—I am, etc.,

Lertonstone, April 3rd.

ARTHUR T. TODD-WHITE.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following notifications are announced by the Admiralty:—Surgeon Captain R. A. Ross to R.N. Hospital, Chatham; Surgeon Commander J. J. Aveling to the *Fernon*; Surgeon Lieut. Commander G. B. Heath to R.N. Hospital, Plymouth; Surgeon Lieutenant S. R. Johnston to the *Greenwich*.
Surgeon Lieutenant E. B. Kelley has been promoted to the rank of Surgeon Lieutenant Commander.

ROYAL ARMY MEDICAL CORPS.

MAY.

- 3 Wed. Edinburgh Branch: South-Eastern Counties Division Annual Meeting, Railway Hotel, Newtown St. Boswells, 3.15 p.m.
- Executive Committee, 3 p.m.
- 5 Fri. City Division, Royal Northern Hospital, Holloway Road, N.7.
- 12 Fri. London: Insurance Acts Committee, 2.30 p.m.
- 17 Wed. Camberwell Division, Camberwell Infirmary. Lecture by Mr. F. N. Doubleday, M.B.C.S., L.D.S., on the Diagnosis of Pyorrhea Alveolaris in its Relation to General Disease, 9 p.m.
- 18 Thurs. London: Conference of Representatives of Local Medical and Panel Committees at Central Hall, Westminster. Principal item of business: Approved Societies and Control of Medical Benefit.

APPOINTMENTS.

LISTER, Lieut.-Colonel A. E. J., M.B., B.S. Lond., F.R.C.S. Eng., I.M.S. (ret.), Honorary Assistant Surgeon to the Western Ophthalmic Hospital, London.

PATRISON, Donald, B.A., M.B., Ch.B., M.R.C.P., Physician to Out-patients at the Hospital for Sick Children, Great Ormond Street, London, W.C.

EDINBURGH ROYAL INFIRMARY.—The following appointments have been made:—Resident House-Physician: J. M. Black, M.B., Ch.B., to Dr. R. N. (six months). Resident House-Surgeon: C. Stewart, M.B., Ch.B., to Mr. Pirie Watson, S.O.P.D. (three months). Non-resident House-Surgeons: S. Young, M.B., Ch.B. (Glasg.), to Dr. J. S. Fraser (three months); Miss Dorothy Mitchell, M.B., Ch.B., to Dr. J. D. Little (six months). Clinical Assistants: W. J. Gibson, M.B., Ch.B., to Dr. J. S. Fraser (three months); Miss Elizabeth S. Forbes, M.B., Ch.B., to Dr. J. D. Little (three months); Miss Agnes G. Brough, M.B., Ch.B., to Dr. J. D. Little (three months); Miss Flora MacDonald, M.B., Ch.B., to Dr. Paterson (three months).

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTH.

WADDY.—On 28th March, 1922, at 23, Woodhead Road, Perry Brown, Huddersfield, to Dr. and Mrs. S. H. Waddy—a daughter.

MARRIAGE.

McMICHAEL—CRAWFORD.—At the George A. Clark Town Hall, Paisley, on 4th April, by the Rev. C. J. T. Merryloes, M.A., assisted by the Rev. Horace Gowan, M.A., Dr. George V. T. McMichael, Medical Officer of Health, Paisley, to Isa, daughter of William Crawford, J.P., Alma, Potterhill, Paisley.

British Medical Journal.

SATURDAY, APRIL 15TH, 1922.

SUNLIGHT AND RICKETS.

It is an old observation that rickets is much less prevalent in the countries of abundant sunshine. B. F. Neve in a communication to the JOURNAL (1919, vol. i, p. 518) stated that in the town of Sriuagar, India, where extreme poverty and most insanitary conditions prevail, rickets is a rare disease; he attributed this to the fact that the sun shone strongly and for nine months in the year nearly all day; while it shines, whether in winter or summer, the poor work and sit about in the sunshine. H. S. Hutchison¹ has recently published an elaborate census of rickets in the town and district of Nasik, India; there rickets was not extremely rare, as among 3,378 children examined, signs of active or healed rickets were found in 381. But the special interest of his article lies in the fact that the population of Nasik falls into two sharply divided classes: a well-to-do class where, owing to the practice of the religious custom of *purdah*, the infants are strictly confined to the dark and stuffy houses, and a poorer class where the infants share with their parents the open-air life of the fields. In the former class the incidence of rickets was 24.9 per cent.; in the latter only 4.8 per cent. This contrast is all the more striking in that the diet of the poorer class compares unfavourably with that of the other in respect of fat and protein, though both are somewhat defective in fat-soluble A vitamin. In both classes the infants were breast-fed for at least one year. Hutchison therefore concludes that rickets is due to lack of fresh air, light, and exercise, and regards the analysis of this clinical material as a confirmation of the views of Noël Paton and Findlay that the predominant factor in the etiology of rickets is not dietetic but hygienic.

It is useful to place alongside this clinical study of rickets some recent experimental investigations in America by Powers, Park, and other workers.² Using rats, kept under ordinary laboratory conditions, they were always able to produce rickets with a diet defective only by reason of its lack of fat-soluble A and of phosphorus; not a trace of rickets appeared, however, if the animals were exposed for about four hours daily to the direct summer sunshine of New York. It is worth adding that where adequate phosphorus was added, and the diet was only defective by its lack of fat-soluble A, rickets did not develop in the shade of the laboratory; and that Hess and Unger,³ in an investigation of about the same date, found that with such a diet and in complete darkness rickets did not develop. It was considered to be proved that direct sunlight was effective in preventing rickets in rats, and also in promoting the general health and vigour of the animals.

It is, however, not a fair inference from the clinical study of rachitic children in Nasik, or the rat experiments described, that lack of sunshine is the cause of rickets. For certainly in the laboratory experiment and possibly in the Indian babies, we have the factor of inadequate diet at work. Powers and Park do not make such a claim, but state that when for any reason, whether dietetic or hygienic, the general metabolism of the young growing animal is weakened, rickets will develop more readily in a dark and confined environment, and can be prevented by an environment of sunshine; that

is as much as to say that sunshine is a powerful influence in the prevention and cure of rickets. Hess and Unger⁴ have reported favourably upon the healing influence of direct sunshine upon babies suffering from rickets, and have confirmed their results by x-ray photographs of the epiphyses; they observed a similar improvement by the use of ultra-violet rays. In the last few years similar results have been obtained by Hulschensky and others. Hess and Unger believe therefore that many cases of rickets are due to defective hygiene rather than to dietary errors, though they admit that diet may be an etiological factor. They explain the much greater prevalence of rickets in winter in the Northern American States by the relative absence of sunlight; and the specially heavy incidence of rickets in the negro population by the failure of light rays to penetrate the thick pigment layer of the skin.

These clinical and experimental observations on sunlight and rickets seem to weigh in favour of the hygienic rather than the dietetic theory of rickets. But most recent writers are careful to reserve a place for the factor of inadequate diet. If we describe rickets as a disease of general metabolism, affecting all cellular tissues at a time when body growth is rapid, and revealing itself specially in a defective deposit of salts of phosphorus and calcium in the areas of active bone formation, it would seem that any substance or influence that will stimulate general metabolism will act towards prevention and cure of rickets. These antirachitic factors may differ widely in their character. Thus Mellanby has shown that lean meat has a definite though moderate antirachitic action in puppies, and attributes its action less to any content of vitamin than to its stimulant action upon general metabolism. There are good grounds, both experimental and clinical, for the belief that sunlight is strongly active in the same way, and there can be no doubt whatever of the antirachitic powers of cod-liver oil. The influence of light as a stimulant of all living cells is well known; and Powers and Park suggest that cod-liver oil may act in the same general way upon metabolism as a whole. The virtue of cod-liver oil cannot lie in its calorie value; and recent observations connect the action of cod-liver oil in an interesting way with the metabolism of phosphorus, the content of phosphorus in the blood plasma being found to be increased after the administration of cod-liver oil. That oil is known to be much richer in the vitamin fat-soluble A than milk or even butter, and though there are difficulties in the view that this vitamin and the antirachitic factor in the oil are identical, it seems probable that the value of cod-liver oil in rickets depends not upon its food value but upon some unknown property by which general metabolism is stimulated. It is an interesting thing that in the prevention and cure of rickets powerful healing agents so diverse as cod-liver oil and sunlight may exert their influence by a similar stimulus to general metabolism; and in the meantime it is safer to assume that in the causation of this defect of metabolism, the prejudicial factor may be dietetic in one case and in another hygienic.

It must be remembered that the experimental work on rickets in America has been done on the rat, an animal whose natural environment is one of filth and darkness; and that it is only when phosphorus is lacking from the diet that rickets has been produced. Thus, in the rat, sunshine is preventive and curative of rickets; but, as Hess and Unger have shown, the lack of sunshine is not causal. This statement seems to indicate that a hygienic factor may cure a case of rickets that has been caused by a dietetic error. The dog is much more sensitive to bad hygienic conditions, and it is now accepted that with a defective diet, rickets is aggravated if the animal is

confined in unwholesome conditions. While Mellanby, however, states that puppies during absolute confinement will not develop rickets if the diet is good, Noël Paton, Findlay, and Watson claim to have produced rickets in pups given an abundant diet of oatmeal and milk, but kept in confinement. The discrepancy between these results may be explained by the fact that in the former cod-liver oil was used, and in the latter it was not.

In view of these conflicting experiments it is not at present possible to give a final verdict on the etiology of rickets, and to assert that it is solely due to faulty diet, or solely to bad hygiene. It may indeed be found that both factors contribute to its production, as both have been found to contribute to its prevention and cure. But recent work on the subject, both experimental and clinical, has brought the different elements of hygiene into a prominent place; and it would be well that Hutchison's careful review of a large number of cases in India both from the point of view of diet and of hygiene, should be followed by similar clinical investigations in this country, in which the conditions of environment as to sunshine, open air, etc., would be scrutinized as carefully as those of the diet.

ANTISEPTIC DYES.

CONSIDERABLE popular interest has been aroused by a paper read recently before the Society of Chemical Industry at Manchester by Renshaw and Fairbrother on the antiseptic action of the coal-tar dyes. The facts mentioned concerning the extraordinarily potent antiseptic properties possessed by many of the coal-tar dyes have not yet found their way into the textbooks in general use, but a very large amount of work has been done on the subject during the last twenty years and many very remarkable substances have been discovered; for various reasons, however, the direct therapeutic results have been on the whole rather disappointing. It is impossible within the space at disposal to present an adequate summary of the work done on the antiseptic action of the coal-tar derivatives, but a few of the most striking results may be mentioned.

Bechhold and Ehrlich in 1906¹ studied the antiseptic action of halogen compounds of phenol and naphthol, and obtained results which show clearly the extraordinary variations in antiseptic action produced by slight changes in chemical constitution, and also the markedly specific action of some compounds. Both these points may be illustrated by stating the minimal lethal concentration for certain micro-organisms of three closely allied naphthol compounds: di-brom-beta-naphthol is fatal to *B. coli* in a concentration of 1 in 30,000, and to *B. diphtheriae* in one of 1 in 40,000; tri-brom-beta-naphthol kills *B. coli* in a concentration of 1 in 2,000, and *B. diphtheriae* in one of 1 in 400,000; tetra-brom-beta-naphthol has a lethal action on *B. coli* in a concentration of 1 in 1,000, and on *B. diphtheriae* in one of 1 in 200,000. It will be seen that di-brom-beta-naphthol has an equal antiseptic action on *B. coli* and *B. diphtheriae*, but that the addition of an atom of bromine greatly reduces the first action and greatly increases the second action. Still more remarkable results have been obtained with the more complex coal-tar dyes, and some instances of extraordinary specificity have been found. Browning, Cohen, and Gulbransen² describe a substance—sensitol red—which has a lethal action on *B. coli* about two thousand times greater than its action on staphylococci.

The specific actions of antiseptic dyes are of course of the greatest value to the bacteriologist in preparing selective culture media. The antiseptic action of coal-tar dyes, such as brilliant green and violet green, has

been used for the disinfection of skin in such regions as the perianal region, which are specially difficult to render sterile.³ It is easy to find a very large number of dyes which act as powerful antiseptics in water at very high dilutions, but only a small fraction of these will exert a powerful antiseptic action in the presence of proteins, and an antiseptic which is to be of use in disinfecting wounds or mucous surfaces must act in the presence of excess of protein. Furthermore, the disinfectant must act on bacteria at a lower concentration than that required to injure the tissues of the host. Only a small fraction of the antiseptic dyes fulfil these conditions.

The flavine dyes introduced into therapeutics in this country by Browning are some of the most successful antiseptic dyes. The activity of most dyes is greatly reduced by the presence of protein—for instance, the antiseptic activity of brilliant green in serum is only 1 per cent. of its activity in peptone water, but the presence of serum actually increases the activity of proflavine tenfold.⁴ Acriflavine and proflavine have both been found to be of service in the disinfection of wounds, in the treatment of gonorrhoea, and as urinary disinfectants.

Internal disinfection in generalized bacterial infections by means of chemotherapeutic agents is, however, the great achievement desired by all those who are investigating specific antiseptics. The achievement of this result might, of course, revolutionize the treatment of a large proportion of human disease. Internal disinfection has been attained to a large extent in the case of trypanosomal and spirochaetal infections, for chemotherapeutic agents are available a single injection of which will cure an animal already moribund from such infections. Nothing approaching this has as yet been found for bacterial infections. The positive results obtained in the treatment of leprosy by the chaulmoogra oil derivatives show that it is possible to destroy bacteria living in the human tissues by the injection of a therapeutic agent.

A certain number of positive laboratory results have been obtained by treating animals suffering from various forms of septicaemia with injections of the flavine compounds and also with injections of quinine derivatives (optochin⁵). A large number of negative results have also been obtained with these substances, and they have not become established as therapeutic remedies for septicaemia. The experiments of Lewis⁶ on the action of dyes on tuberculosis illustrate the difficulties involved in experiments of this nature. Lewis obtained dyes which had a marked specific action on the tubercle bacillus *in vitro*, and when injected into the living animal could penetrate to the centre of the masses of diseased tissue, and yet he could find no substance which had a markedly beneficial effect on the process of infection in man or animals.

The few instances mentioned above serve to illustrate the point mentioned at the beginning of this article. An enormous amount of work upon specific bacterial disinfectants has been done, and much valuable information has been obtained, and yet the results are on the whole rather disappointing. They are disappointing because they fail by such a narrow margin to achieve much greater things. It would seem that with the knowledge now possessed we ought to have drugs which would produce the same effect on septicaemia as salvarsan does on syphilis. The attainment of this effect has been approached many times by many different workers, but yet in every case partial or complete failure has resulted.

THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE President of the Royal College of Physicians of London is elected annually on the Monday following Palm Sunday. On April 10th Sir Norman Moore, who has held the Presidency with much distinction for the past four years, intimated his wish not to be re-elected. Sir Humphry Davy Rolleston, K.C.B., M.D., was elected President in his place and duly inducted by the Senior Fellow present. The new President, who is a graduate of Cambridge in Arts and Medicine and Emeritus Physician to St. George's Hospital, was elected a Fellow of the College in 1894, and his election to its highest office will be welcomed on every ground by the medical profession. He is a former scholar and Fellow of St. John's College, Cambridge, and a student of St. Bartholomew's Hospital. In the South African war he was consulting physician to the Imperial Yeomanry Hospital, Pretoria. From 1914 to 1919 he served as consultant physician, with the rank of surgeon rear admiral, in the Royal Navy; for his services, recognized throughout the navy, he was created C.B. in 1916 and K.C.B. in 1918. Sir Humphry Rolleston is a past-President of the Royal Society of Medicine, and on the occasion of the annual meeting of the British Medical Association at Newcastle last year received the honorary D.C.L. degree of the University of Durham. He holds many other academic honours, both British and foreign, and has served with distinction on numerous boards and public committees. His name is associated with that of Sir Clifford Allbutt as joint editor of the second edition of the standard *System of Medicine*, and his clinical learning and scholarship are shown in his writings on diseases of the liver and many other publications. He was Goulstonian Lecturer of the Royal College of Physicians in 1895, Lumleian Lecturer in 1919, and was Senior Censor at the time of his election to be President. On many occasions he has given most valuable assistance to the British Medical Association as a member of its Science Committee and of the Arrangements Committee for the scientific work of the Annual Meetings. He was secretary of the Section of Pathology and Bacteriology in 1895; vice-president of the Section of Medicine in 1899, of the Section of Pathology in 1904, of the Section of Diseases of Children in 1910; and president of the Section of Medicine at Cambridge two years ago.

ANTITYPHOID VACCINATION BY THE MOUTH.

ATTENTION has already been drawn¹ to the fact that Professor Besredka has prepared an antityphoid vaccine, combined with bile, which, he claims, will produce satisfactory protection against typhoid when administered by the mouth. The importance of the matter is obviously very great, for it is very difficult to get men even when under military discipline to submit voluntarily to antityphoid inoculation, and it is almost impossible to get inoculation carried out effectively in a civil population. Our previous note on this subject was short because at the time of writing there was no record of any practical application of the method on which to base a judgement. The result of a trial on a fairly extensive scale has recently been published by Dr. Vaillant,² the medical inspector of the health department of the Pas de Calais. An epidemic of typhoid broke out last autumn in six of the villages in the devastated region of the Pas de Calais. That considerable section of the British medical world which has first-hand experience of the sanitary conditions of such villages will appreciate the danger of such an outbreak. Antityphoid inoculation was commenced, but had to be discontinued because the only persons who would submit to it were the inhabitants of one village where the epidemic had been particularly severe. The administration by mouth of Besredka's antityphoid vaccine and bile was then tried. The details given are not very precise; Vaillant merely states that each inhabitant took on an empty stomach, on first getting up, a bile pill and a compressed tablet containing a mixture of typhoid, paratyphoid A, and paratyphoid B

bacilli killed by heat. In adults the dose was repeated for three mornings in succession; in children for only two mornings. The results are stated to have been remarkably successful. Among the non-vaccinated persons, estimated to number from 400 to 650, fifty cases of typhoid fever occurred; that is to say, about 8 per cent. of the non-vaccinated persons were attacked; 173 persons were vaccinated hypodermically (with T.A.B.); of these four, or 2.3 per cent., suffered from typhoid fever. The number of persons given Besredka's antityphoid tablets by the mouth was 1,236, and of these only 2 (0.17 per cent.) developed typhoid fever. There are certain sources of error in these figures which need consideration. About half the cases of typhoid occurred before prophylactic measures were commenced, and it was the inhabitants of the most severely infected village who submitted to hypodermic inoculation with T.A.B. Hence the figures as to the non-vaccinated and as to those vaccinated hypodermically appear to be more unfavourable than was in fact the case. After allowing for these errors, however, the figures afford strong evidence for the value of Besredka's method. The real value of any antityphoid measure is of course a question of very great practical importance, for the safety of a community may depend upon the efficacy of the methods employed; hence extreme caution is demanded before any new method is finally accepted. The figures quoted, however, supply strong *prima facie* evidence for the value of the new method; it is to be hoped that it will be further tested on as large a scale as possible whenever opportunity occurs.³

THE PASTEUR CENTENARY AT STRASBOURG.

THE centenary of the birth of Pasteur is to be celebrated at Strasbourg in May, 1923, when a monument is to be inaugurated to his memory in front of the University of Strasbourg, where he taught from 1849 to 1854. Pasteur was born at Dôle, in the Department of the Jura, on December 27th, 1822. His first appointment was to teach physics at a school in Dijon, but he did not remain there long. At the end of 1848 he became a member of the faculty of the University of Strasbourg; he began work there in January, 1849, as a teacher of chemistry, and married shortly afterwards. It was there that he completed work begun in Paris on tartaric and racemic acids, and there also that he made his first tentative experiments with micro-organisms. He remained at Strasbourg until 1854, when he was appointed professor and dean of the science faculty then newly constituted at Lille. As at present arranged the inaugural ceremony at Strasbourg will take place on May 1st, 1923, and it is hoped that it will be attended by members of Pasteur's family, and by M. Roux, director of the Institut Pasteur, Paris, by other representatives of that institute, and by delegates of the Institut de France and other learned bodies in that and other countries. A congress of hygiene and bacteriology will be opened on the same day in Strasbourg, as well as an exhibition designed to illustrate the advances made in various branches of science as the result of Pasteur's discoveries. The scheme has the support of the President of the French Republic, M. Millerand, of M. Loubet, who was President of the Republic during the war, of M. Leredu, Minister of Hygiene, and of M. Alapetite, Commissioner General of Alsace and Lorraine. A committee has been formed in this country to support the scheme, with Sir Charles Sherrington, G.B.E., M.D., President of the Royal Society, as chairman; Mr. A. Chaston Chapman, F.R.S., President of the Institute of Chemistry, as treasurer; and the following members: Mr. H. E. Field, President of the Institute of Brewing; Professor Percy F. Frankland, C.B.E., F.R.S., Emeritus Professor of Chemistry, University of Birmingham; Sir John McFadyen, M.B., B.Sc., LL.D., Principal of the Royal Veterinary College; Professor C. J. Martin, C.M.G., M.D., F.R.S., Director of the Lister Institute; Sir W. J. Pope, K.B.E., F.R.S., Professor of Chemistry, University of Cambridge; Sir James Walker,

¹ BRITISH MEDICAL JOURNAL, January 21st, 1922.

² *Annales de l'Institut Pasteur*, T. 36, p. 149, 1922.

³ Tablets made according to Besredka's formula can be obtained from Sealand Trading Limited, 24, Holborn, London, E.C.1.

F.R.S., President of the Chemical Society; and Sir Almroth Wright, K.B.E., M.D., F.R.S. We feel sure that the scheme will be welcomed in this country, and that among those who will wish to support it are many members of the medical profession, who know perhaps better than those of any other calling how great and beneficent have been the effects of Pasteur's pioneer work in bacteriology. Subscriptions may be sent to Mr. A. Chaston Chapman, at the Institute of Chemistry, 30, Russell Square, London, W.C.1, or to M. Th. Hering, 6, rue des Veaux, Strasbourg, the general secretary, and treasurer of the French Committee. The subscription list will be closed at the end of June next. It is hoped also that manufacturers and other business firms in this country will take part in the exhibition, full particulars of which can be obtained on application to Professor Borrel, 3, rue Koeberlé, Strasbourg.

SCIENTIFIC SECTIONS AT THE GLASGOW ANNUAL MEETING.

At the forthcoming Annual Meeting of the British Medical Association at Glasgow the officers of the Section of Physiology have arranged the following programme. On Wednesday, July 26th, there will be in the morning a joint meeting with the Section of Diseases of Children, when the subject for discussion will be "Rickets." Dr. Leonard Findlay, of Glasgow, will introduce the subject from the clinical side, and Professor E. Mellanby, of Sheffield, will open from the physiological side; later in the discussion there may possibly be a paper on "Dental hypoplasia and rickets," by Dr. J. Sim Wallace of London. On the morning of Thursday, July 27th, there will be a meeting of the Section at which the subject discussed will be "Basal metabolism," with an opening paper by Professor E. P. Cathcart of Glasgow. In the afternoons of both days there will be demonstrations in the Physiological Institute. The officers of the Section of Obstetrics and Gynaecology have made the following provisional arrangements. On the first day there will be a discussion on "Stillbirths and pre-natal deaths"; it is hoped that the speakers will include Dr. Ballantyne, Dr. Eardley Holland, Dr. Browné, Professor Kennedy, Dr. Cruickshank, Dr. Strachan, and Dr. Lindsay. For the second day the following discussions are provisionally arranged: (a) "Surgical treatment of prolapse," opened by Dr. W. E. Fothergill; (b) "Treatment of eclampsia," opened by Dr. T. W. Eden; (c) "Anæsthetics and analgesics in labour," opened by Dr. Greenwood. The names of the officers of the scientific Sections were printed in the SUPPLEMENT of February 18th, at p. 39. The Sections will meet on Wednesday, Thursday, and Friday, July 26th, 27th, and 28th.

SMOKE PREVENTION AND PUBLIC APATHY.

LORD NEWTON, the Chairman of the Departmental Committee on Smoke Abatement, has complained lately of the absence of public interest in that inquiry. The impressive evidence which the Committee received as to waste, pollution, and disease in consequence of the smoke nuisance had, he said, been passed over by the press almost without notice. Only once had his Committee a glimpse of public renown. It happened that while visiting an industrial district in the north he was the guest of a peeress who had been engaged in the arduous operation of harvesting oats, and owing to the smoke of neighbouring factories, her blouse, which was white when she began, was black before she finished. This blouse caught the public imagination, and bade fair to rank among the celebrated garments of history. It was photographed for the illustrated papers, it appeared on exhibition in London, and it had now found a permanent home in the museum of an important provincial city, where it remained, said Lord Newton, an illustration of our sooty skies and of the labours of our nobility. After this sensation his Committee sank again into oblivion. Not a member of Parliament had had the curiosity to ask whether the Government contemplated legislation to deal with the evil. Lord Newton believed that, however much Englishmen might pride themselves on their personal cleanliness, England was

certainly the dirtiest country in Europe, and possibly in the world, owing to its indiscriminate and wasteful use of raw coal for all purposes, domestic and industrial. Recently he had visited Germany, which was looked upon as a law-ridden country, but he found that there was less legislation on this subject than in the United Kingdom; yet when he compared Cologne and Düsseldorf with Manchester and Sheffield he felt a sense of degradation. There was no great pressure on the part of the Government in Germany, and the cleanly state of the cities in this industrial Rhine district was really due to the application of common sense and a determination not to tolerate nuisances. In England, when a man made a fortune out of industry he retired as far from the factories as he could; in Germany he remained within the urban boundaries, because life there was physically as pleasant as it was outside, and much more interesting. Lord Newton's remarks were preliminary to a lecture by Dr. Saleeby on the effects of sunlight as observed among the children at Leysin under Rollier and at Alton under Gauvain; and a resolution, commended to the meeting by Sir Henry Gauvain, was adopted, calling upon the Minister of Health to give effect to the recommendations of Lord Newton's Committee.

MILD SMALL-POX.

Records of outbreaks of mild small-pox or alastrim accumulate; the most recent is contained in a report by Dr. Boobyer, medical officer of health for Nottingham. He recalls how, more than twenty years ago, he reported certain cases among Mormon missionaries who had visited Nottingham, and who were responsible for subsequent prevalence in the Midlands. He has now, since early in 1921, had a series of cases, numbering altogether 113, without a death; he however objects to the view that alastrim—if the name be accepted—is persistently mild, seeing that one unvaccinated adult had a severe confluent attack and barely escaped with her life. Owing to the mildness of the attack in many of the cases, especially of young unvaccinated children, it was commonly reported even by medical practitioners that they were suffering from varicella, but a careful study of the cases, and of the age incidence upon the unvaccinated and vaccinated respectively, confirmed the diagnosis of small-pox; incubation period, prodromal and onset symptoms, and rash all pointed to small-pox—in some cases of so mild a form that a magnifying glass was necessary to reveal the typical features of papule, vesicle, pustule, or scar; these features, however, were present and apparent when carefully sought for. His table of cases illustrates the remarkable reversion of age incidence which is taking place under the influence of neglected infantile vaccination. In the days of Jenner small-pox was, like measles and whooping-cough, a disease of childhood. The practice of vaccination under the obligatory laws gradually drove it from childhood into later life, which was unprotected for want of systematic revaccination. Now again, however, children are, in constantly increasing numbers, unprotected; and Dr. Boobyer's figures show how amongst the unvaccinated small-pox is once more finding the bulk of its victims in the young. In the vaccinated section of the population, on the other hand, small-pox still avoids childhood, and the mild type in Nottingham found vulnerable no vaccinated individual under thirty years of age. Fortunately for all concerned, the disease was so trivial that the punishment exacted from the young for the folly of their parents consisted only of non-fatal attack, instead of the high fatality which would have accompanied an outbreak of the variola of the standard type of former years.

A MEDICAL POSTMASTER-GENERAL OF THE UNITED STATES.

DR. HUBERT WORK, President of the American Medical Association, took the oath of office as Postmaster-General of the United States on March 4th. Dr. Work is the first member of the medical profession to receive Cabinet rank in the United States since Dr. James McHenry served as

Secretary of War in the Cabinets of Washington and Adams. He is said to have been the youngest medical practitioner ever elected president of the Colorado State Medical Society, and for four years he was also President of the Board of Health of that state. He has been a member of the House of Delegates of the American Medical Association since 1904, and in 1916 he was elected Speaker, a position which corresponds to that of Chairman of the Representative Body of the British Medical Association. He became President-elect of the American Medical Association in 1920, and is now actually serving as President of the Association. During the war he was medical adviser to the Provost Marshal-General, in which position it is stated that his diplomatic qualities were of inestimable service. President Harding, when he took over the reins of government, appointed him First Assistant Postmaster-General, and he now becomes Postmaster-General in succession to Mr. Will H. Hays, who resigned to accept a very highly paid post as organizer of the cinematograph industry. Dr. Work's appointment was unanimously confirmed, without the usual reference to a committee, within an hour after his nomination was received by the Senate, in spite of the fact, as the *Journal of the American Medical Association* records, that senators and representatives were bombarded with telegrams, letters, and petitions from the antimetrical faddists in general and in particular from those to whom scientific medicine is anathema.

A CORONER ON UNQUALIFIED PRACTICE.

Our attention has been drawn to newspaper reports of a recent coroner's inquiry, held at Spennymoor, co. Durham, into the death of Mary Ellea Kay, a married woman staying at her parents' house for her confinement, with an uncertified midwife in attendance. According to these accounts it appears that the midwife, on March 23rd, sent for an unqualified man named Ross, who had been chosen by the family to attend Mrs. Kay, and had previously visited her. In his evidence Ross described himself as an unregistered medical practitioner who had for the past twenty years been in practice in the district; on an average he attended 180 confinements a year. After visiting the patient on this occasion he told the parents that owing to her condition and the fits from which she was suffering it would be advisable to get further medical aid. He then wrote a note to Dr. Pattullo asking him to attend, but left before any doctor came because he knew that whilst he was there a qualified man would not come. He saw that an anaesthetic was necessary, and that therefore two practitioners were required; he himself had no assistant. Further evidence showed that the case was then taken over by Drs. Mussellwhite, Pattullo, and Charlton; an operation was performed and the woman was delivered of twins, one dead but the other alive. The mother died the following day from puerperal eclampsia. Dr. Pattullo, in answer to the coroner, said he would not like to give any definite opinion as to whether there were any ill effects due to delay; but in his opinion to leave the case alone was very bad practice indeed. He added that the qualified medical practitioners in the town strongly resented that Ross should be in a position to call in a doctor. To this the coroner replied that he did not think the jury were concerned with the dispute between Mr. Ross and the qualified men. The jury having returned a verdict in accordance with the medical evidence, that Mrs. Kay's death was due to puerperal eclampsia, Dr. Pattullo rose to protest, on his own and Dr. Mussellwhite's behalf, against being called upon to attend Mr. Ross's difficult cases. The coroner said that this was not a matter for the jury, or himself as coroner. Dr. Pattullo replied that they had decided not to attend if Ross called them again. Upon the coroner advising him not to use any threat, Dr. Pattullo explained that it was only a warning. The coroner then made the following observation: "If there is any negligence by which a life is jeopardized, and I have anything to do with it, it may amount to manslaughter, and that is all I can say. I would not spare anyone, either

qualified or unqualified." The coroner's statement in this case appears to have been entirely uncalculated for and notwithstanding intelligible. He is generally understood to have implied that if a life is lost as a result of a doctor failing to attend a patient when summoned, the doctor may find himself indicted for manslaughter. This is a view of medical obligations for which there is no justification. A doctor is not required to attend in response to a summons save from one in regard to whom he is under contractual obligations, such as an employee of a firm with which he has contracted, or an insured person on his list, or a woman whom he has definitely agreed to attend in her confinement. In this case it does not seem that any such relation existed; so far as can be gathered from the reports in the newspapers the woman was not an insured person, and Ross had been engaged to attend her in her confinement. As a matter of custom the doctor's right to refuse to attend in a case of urgency is rarely exercised, and it is well known that in such circumstances a large amount of medical attendance is given for which no remuneration is ever received. It is this very altruism which has led to the exploiting of the medical man and given rise to the belief in some quarters that he is at the beck and call of anyone who chooses to send for him. It is desirable that coroners and others should understand that this is not the case; still less is it incumbent upon a practitioner to attend when he is not sent for by the patient or a responsible relative or guardian of the patient, but by a person who has no legally recognized status towards the patient. This inquest once again calls attention to the evils of unqualified practice, but we fear that no steps will be taken to alter the present position until public opinion has been educated more closely to the level of medical opinion. It is not an offence in this country for an unqualified person to practise medicine, provided he does not wilfully and falsely pretend that he has a medical qualification or that he is recognized by law as a physician or surgeon. The General Medical Council has no power to initiate proceedings against unqualified practitioners of medicine. Where, however, there is reason to suppose that the Medical Acts have been infringed the facts should be laid before one of the medical defence societies, which have often successfully prosecuted offenders.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.

The arrangements for the short course in general medicine from May 1st to 13th, as already announced, are now complete, and lectures and demonstrations will be given at the following institutions: National Hospital for Diseases of the Heart, Bethlem Royal Hospital, Royal Westminster Ophthalmic Hospital, Paddington Green Hospital for Children, Middlesex Hospital, London Lock Hospital, St. Mark's Hospital, Maida Vale Hospital for Paralysis and Epilepsy, Brompton Hospital, and St. George's Hospital. Application for copies of the syllabus and tickets admitting to the course should be made to the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W.1. This course will be repeated during the summer, and others of a like nature in children's diseases, tropical medicine, etc., are in course of preparation. The series of lectures at the Royal Society of Medicine, 1, Wimpole Street, announced last week, will commence on Monday, May 1st, and the opening lecture will be delivered at 5 p.m. by Sir Humphry Rolleston, on "Recent physiology of the liver and its application in practice." Other lectures for May will be as follows: Tuesday, 9th, Sir Arbuthnot Lane, "Fractures"; Tuesday, 16th, Sir Thomas Horder, "The clinical significance of haemoptysis"; and Wednesday, 24th, Sir St. Clair Thomson, "The surgical anatomy of the nose and accessory sinuses" (lantern demonstration). The complete list of lectures to the end of July will be forwarded on application to the Secretary to the Fellowship of Medicine.

A NATIONAL Congress of Hygiene will be held at Naples in May, when the principal subjects for discussion will be alcoholism in its various aspects, sexual hygiene and prophylaxis, and personal cleanliness.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

National Insurance Bill.

Explanation by the Government Actuary.

SIR ALFRED W. WATSON, Government actuary, has issued a document in explanation of the financial provisions of the National Health Insurance Bill. He deals first with the additional charge which it is proposed to make until December 31st, 1923, on the funds of approved societies and the Deposit Contributors' Fund in respect of the cost of medical benefit, in order to relieve the Exchequer of substantial payments hitherto met out of special grant voted by Parliament. He estimates that the additional cost to insurance funds, during the period from April 1st, 1922, to December 31st, 1923, will be as follows:

Country.	Maximum Charge per Insured Person per Annum.	Aggregate Charges, April, 1922—December, 1923.
England	s. d. 2 6	£ 2,750,000
Scotland	2 11½	450,000
Wales	3 1½	220,000
Great Britain	—	3,420,000

The Government actuary points out that the bill provides that the whole of the above sum shall be met in the first instance out of Insurance Funds without recourse to the Exchequer, and that the usual State grants of two-ninths of benefit shall not be paid when the sums in question are disbursed. Under the proviso to the clause, however, power is taken to recoup at a later period societies in respect of the loss of State grant. This means, although Sir Alfred Watson does not precisely say so, that the societies, in shouldering the extra burden, are not to lose the aid of the usual State grant of two-ninths of the benefits. If the aggregate sums to be applied as stated had not been required for the purpose named, they would have formed part of the surpluses disclosed at the next valuation of societies, and in general would have inured to the members in the shape of additional benefit, two-ninths of which would be defrayed out of the Exchequer. The bill accordingly provides that the funds of societies shall be recouped by a grant after the next valuation, as though the sums now disbursed for medical benefit were then made available, with such interest additions as in the meantime would have accrued in respect of them for additional benefits. Sir Alfred Watson estimates that under this arrangement a sum of £180,000 a year will fall to be paid by the Exchequer for the period of five years beginning April 1st, 1925. Approximately, of the total sum of £900,000 so payable, £140,000 will be in respect of the interest additions. In the circumstances the sum of £900,000 is not an additional charge, but substantially one which would have come in the course of payment in those years under the normal arrangement of the scheme of National Insurance.

Sir Alfred Watson next shows how it is that the approved societies are able to meet the additional charges contemplated without requiring increase in the contributions of insured persons or their employers. During the first six years of the Act the great majority of approved societies accumulated substantial surpluses by reason of their light sickness experience and other elements of gain operating during the period. The aggregate surpluses of societies and branches in Great Britain reached £16,850,000, of which amount sums amounting to about £9,000,000 were certified as disposable surplus and available for the purpose of granting additional benefits to the members of the societies concerned. Surpluses amounting to nearly £8,000,000 were thus carried forward.

In addition to these surpluses, contingency funds amounting to over £6,000,000 had been accumulated by societies, and these also were carried forward, almost intact, as a further reserve to the benefit funds of societies, to which, in fact, they failed to be transferred as on January 1st, 1919. Apart, therefore, from the sums made available for additional benefits, the benefits funds of approved societies, taken collectively, were some £14,000,000 in excess of their liabilities for benefits. It was, however, important to bear in mind that the several societies and branches were independent financial units, and that (subject to certain special and limited arrangements for the protection of small societies and branches) each society or branch was entitled only to resort to its own portion of this aggregated sum. Having regard to this point, and to the fact that the acute and prolonged unemployment from which the community is now suffering has caused heavy loss of contributions, and may bring other serious losses, the actuary holds that the greatest care must be exercised in imposing new burdens upon the societies. The proposals in the bill in respect of medical benefit contemplate a charge, limited in amount and temporary in operation, and he thinks that this may be safely borne; but he wishes it to be clearly understood that his opinion stops there.

In regard to the abolition of the Exchequer grant to the Women's Equalization Fund, the Government actuary mentions that the sum amounts at present to £350,000 per annum. The purpose of the fund was to assist societies in respect of the sickness of their married women members by supple-

menting the contributions of this class of insured persons. It is proposed in lieu of the maintenance of this fund that additional reserve values should be credited to societies in respect of married women members. The actuary estimates that the reserve values required for the purpose will amount to about £1,000,000 at the outset, with an annual addition of about one-tenth of this sum as insured women marry.

Coming to the intended change in the disposal of unpaid contributions, Sir Alfred Watson says that at present nine-tenths of any sums set free from the Stamp Sales Account is carried to the Central Fund and the remaining tenth may be applied to other purposes. Power is taken in the bill to reduce the amount to be carried to the Central Fund, and to make such payments to approved societies as will enable them to avoid the suspension from monetary benefits of members who have suffered prolonged unemployment through the industrial conditions. The amount of the charge thus expected to arise will depend primarily on the number of persons owing twenty-six contributions or more at the end of next June. Judging by the estimates prepared in connexion with the Unemployed Insurance Bill, it appears probable that at least one million persons will thus be in arrears, and on this basis a minimum expenditure of £250,000 out of the contribution money must be contemplated. The total expenditure may be considerably greater, but it is understood that the balance available is well in excess of any demand that is likely to arise, assuming that the payments in individual cases are governed by the normal regulations as to arrears.

Public Assistance Expenditure.

Sir J. D. Rees raised a debate on April 4th as to expenditure on public assistance. His motion alleged that the expenditure in this connexion had risen from twenty-five millions sterling in 1890-91, to three hundred and thirty-two millions in 1920-21, and would probably be not less than four hundred millions in 1921-22, and that thirty million persons, exclusive of unemployed, out of a population of forty-eight millions, had been in receipt of such public assistance in 1919-20. His resolution asked that a Royal Commission or Board should be appointed to ration such expenditure.

Mr. W. Graham, one of the most thoughtful members of the Labour party, took the view that large expenditure on social services was inevitable, at any rate until the housing problem had been tackled, and industry placed in a better position.

Mr. Hilton Young, for the Government, said that the increase in prices and in wages had made it much more costly to carry on the social services—twice as costly as in 1891, with which year comparison had been made. Another point to be remembered was that the population had risen since then from thirty-eight millions to forty-seven. Those considerations should be weighed, along with the fact that new services had become inevitable. The real remedy was in watching the estimates.

Mr. Macquisten, touching a remark by Mr. Young, that nobody would think of repealing the National Insurance Act, held, on the contrary, that this would be a popular thing to do. If the same principle were to be applied to the legal profession—if the public were required to hand over so much a week to a panel solicitor or barrister for the purpose of getting advice—the legal advice obtained in such circumstances would be the same kind of advice, he imagined, as the medical advice given by the panel doctor. A profession could not be worked in this way. It was merely a tax upon unfortunate people for the support of a profession. No doubt the majority of doctors still had the old professional standard, and he believed it would last for many years. The general effect had been to provide men, who could not get practices in the ordinary competition in the medical profession, with a very satisfactory beginning. The thing was carried on by inflicting penalties upon very poor people who could get no benefit from it. For instance, the mariners got nothing out of it; they were all at sea, and were treated at the expense of the shipowners, and yet they were fined for this purpose. The very nurses, who had all their medical attention free, had been brought in to pay a tax for the benefit of other people. It was a monstrous imposition.

The motion was afterwards withdrawn.

Local Government Officers' Superannuation.

Sir Herbert Nield, on April 7th, moved the second reading of the Local Government and other Officers' Superannuation Bill, which he had introduced as a private measure. He explained that it was a purely optional proposal, the object being to enable authorities to adopt the provisions as they might think fit. The number of public servants who would be eligible to come under the bill was 38,500 officers and 167,000 working men. At present 60,000 officers as well as 200,000 workmen who were employed by local authorities were covered by schemes. Some others were also covered by Local Acts. The measure was based on the Middlesex Act of last year. The desire was that superannuation schemes should not be dependent upon private bill legislation, which involved delay. Sir Herbert added that he was willing to extend the proposals to part-time officers when the bill went into Committee. Mr. Neville Chamberlain, seconding the motion, claimed for it three advantages: It would enable a local government authority to attract to its service a better class of men than it could otherwise get; it would enable the authority to keep officials in its service for many years; and would enable such to remove an official who had ceased to be efficient through old age, without doing him an injustice or running contrary to its own national feelings.

Sir Alfred Mond said it was the intention of the Government on

time to introduce a compulsory bill to cover the question of superannuation of officers of local authorities throughout the country, but it was felt that the imposition of such a heavy burden could hardly be faced at the present time. The bill before the House being permissive, he did not object to a second reading. He pointed out, however, that the thirty clauses raised very difficult questions—he was advised there were serious defects in the actual provisions, and there was involved a risk of expenditure up to three or four millions a year by local authorities.

After further discussion the bill was read a second time and referred to a standing committee.

Insurance Pharmacy Terms.—The Ministry of Health is about to issue the revised scale of terms of payments to be made to panel chemists for two years from May 1st. The rate for compound liquid medicaments (excluding preparations specified in the table for drug prices for proprietary preparations) will be reduced to 5d. per prescription, and the rates in respect of the remaining items in the dispensary fee scale will be reduced 1d. per prescription. Further reference to this matter appears in a Current Note in the SUPPLEMENT this week.

The Cost of Health Insurance.—On inquiry by Sir J. D. Rees, on April 5th, Sir A. Mond said that in respect of health insurance in England and Wales, the total charge upon the State for the year 1920-21 was approximately £9,500,000, and for the year 1921-22 was estimated to be £9,000,000. The contribution of employers and employed were in 1920-21 approximately £21,400,000, and in 1921-22 were estimated at £21,600,000.

Royal Army Medical Corps.—Dr. Fremantle asked, on April 4th, the number of officers at present serving in the R.A.M.C. who had passed the age for retirement, thus preventing the promotion of senior majors in the corps; and whether all officers who were past retiring age would now be retired. Sir L. Worthington-Evans said the answer to the first part of the question was none, and the second therefore did not arise.

Dentists' Register.—Replying to Colonel Wedgwood, on April 5th, Sir A. Mond said he understood that it was the custom of the Dental Board, in the case of applicants for registration who had been employed by another unregistered practitioner, to accept a sworn declaration by the employer as corroboration of the statement made by the applicant himself.

Lunacy Reform.—Sir A. Mond, on April 5th, informed Captain Loseby that he still hoped to be able to introduce a Lunacy Reform Bill, but that depended upon the time of the House and other matters not under his control. If he did not introduce a bill he would reconsider the suggestion for the setting up of a Royal Commission.

Small-pox Hospital for Southampton.—Sir A. Mond stated, on April 5th, in answer to Major Heussen, that he had no objection in principle to the scheme of the Southampton Town Council for the acquisition of a small-pox hospital from the Winchester Rural District Council and of certain other small-pox hospitals in the country. He was advised, however, that a local inquiry should be held before sanction could be given. He was ready to hold inquiry immediately on receipt of certain information for which he had asked in September last.

Coroners' Courts.—In reply to Major Claude Lowther, on April 4th, Mr. Shortt said that it was proposed to deal in the Coroners' Bill with the duplication of proceedings in magistrates' and coroners' courts, but he could not say at present when the bill would be introduced.

Income-tax Assessments.—In response to Mr. Marriott, on April 7th, Mr. Young said the number of individuals in Great Britain and Ireland with incomes above the exemption limit for the year 1921-22, was provisionally estimated at five millions, divided as follows:

Number actually paying income-tax	2,401,000
Number whose incomes are covered by the personal allowances and deductions and reliefs	2,600,000

The number of individuals liable to super-tax for the year 1922-21 (based on the income-tax income for the previous year 1919-20) on incomes of £5,000 and over and assessed thereto up to February 28th last was as follows:

£5,000 and under £10,000	15,799
£10,000	220,000
£20,000 and over	6,389
	3,167

These numbers were not final, as further assessments to super-tax will still be made.

The Purity of Milk.—Sir Alfred Mond, on April 6th, assured Mr. T. Thorson that he was carefully considering—in framing a new bill—the desirability of enabling local authorities to assist in securing improved supplies of milk in their area by means of classification and by having the power to revoke or suspend certificates, and of registration of all milk sellers in their area.

Deaths from Starvation.—On inquiry by Mr. R. Richardson, on April 6th, Sir A. Mond stated that no deaths from starvation or exposure were reported by the coroners as having occurred during the year 1919 in the counties of Durham, Yorkshire, and Berkshire, but in 1920 five were reported as having occurred in Durham and one in Yorkshire.

Paris.

(From our Correspondent.)

PROGRESS IN MEDICINE.

"Surgery makes great strides. Medicine does not." This is one of those asinine little statements which may be heard almost daily. The reason is that surgery is spectacular. You cannot see such remarkable results as those reported by Nicolle to the Académie des Sciences a few days ago. The director of the Pasteur Institute of Tunis has been working on the possibility of preventive vaccination against Mediterranean fever.

A hundred billion sterilized *Micrococci melitensis* are given by the mouth daily for four days in succession; sixteen days later 450 million micrococci are injected hypodermically. No trouble is noticed. A volunteer acting as control, injected at the same time, developed a typical attack of fever, which was promptly stopped by curative vaccine. Exactly similar results were obtained with Shiga bacilli. We may hope, therefore, to vaccinate against Malta fever and bacillary dysentery by giving pills by the mouth, and it is quite legitimate to expect that cholera and typhoid fever will prove amenable to the same simple prophylactic measure. It is to be noted also that Vaillant has tested Besredka's method of giving killed vaccine and bile in a recent epidemic of typhoid in the north of France with encouraging results.

The question remains, how long such an immunity may last. At any rate, the method is an immense improvement on the inoculation methods owing to the great facility it affords for making prophylactic methods acceptable to the people, and so bringing the stamping out of epidemics within the scope of practical administration.

The fight against syphilis is well started. Weapons already available are effective, and new ones are being added to the arsenal. The bismuth salts are being actively tested and seem to answer Levaditi's claim. The *Barrister Medical Journal* has lately reviewed the whole question, and little is to be added. We are still in the period of expectation and experimentation. If we had a practical test allowing us to measure the degree of luetic infection and to characterize the condition of "cure," we would be very far advanced in the choice of the weapon to use. The Wassermann test is fallacious. We build great hopes—and some of us even more than hopes—on Vernes's reaction. He has proved that the serum of syphilis is physically affected so that it contains "something that may be measured." That something affects flocculation under determined conditions, and flocculation is measurable by optic methods. Hence the discovery of *syphilimetry*, which allows us—and this is new in the story of biology—to measure a degree in infection just as we measure a degree in temperature. A prophylactic institute is in full work in Paris (at the expense of the city council), and the method is spreading over the country. Statistics show that over 30,000 cases have been actually followed, and that means that serologic verifications, both on blood and cerebro-spinal fluid, number more than 400,000. How such work can be carried on at the rate of about 1,200 consultations a week can only be understood by those who spare a few hours to visit the institute in full work. It is all clinical organization and laboratory Taylorization. I looked over the visitors' book a few days ago. Medical men from all over the world had signed their names, but British visitors seem to be the very rare exception. The channel seems wide.

M. Pozerski, of the Pasteur Institute, is perhaps going to help to bridge it. He has been experimenting on sea sickness by the means of a clever mechanical apparatus allowing him to swing a cage exactly in the way a ship on a high sea moves. The involuntary passengers behave in very different ways. Rabbits, guinea-pigs, fowls, and pigeons are good sailors and do not mind six hours of stormy weather. But our friend the dog is, alas! more human, for of the dogs tested 30 per 100 were seasick—10 per cent. with asthenic symptoms and 20 per cent. with symptoms of excitement. Some got accustomed after the second "crossing." But how are we to argue from animal to man? Some dogs which have once been affected by experimental sea sickness are ill again and start vomiting as soon as they board the cage, and even before the engine is started. Clearly canine imagination is closely akin to ours, a similarity which might open a new field for M. Emile Coné in the veterinary world.

Our ears are buzzing on this side with the reception given to this gentleman in London. We did not know that we possessed so great a prophet. As a matter of fact M. Coué has taught us a practical lesson in psychology, which is that imagination is stronger than will. He has shown also that we can master our imagination by minor devices, as though we made a mould into which our subconscious self shapes itself, and our organs follow suit, shaking off the old bad habits that we call ailments. M. Coué is a humanitarian philanthropist and works *pro Deo*. Strangely enough, he is a retired pharmacist of Nancy, and we are puzzled to know whether or not it is surprising that a dispensing chemist turns out to be so sceptical as regards *materia medica*. At any rate he found out that auto-suggestion is just as good as hetero-suggestion, and he must be given the credit of striving to teach the patient not to depend on him. Twenty knots on a bit of string and a simple catch phrase: what a simplification! The medical profession on this side has not had a chance yet to meet M. Coué, and I venture to think that even if we invited him to practise in Paris the police might object. It is not so long since the pithy verses were written on the closed door of St. Médard:

De par le roi, défense à Dieu
De faire ses miracles en ce lieu.

India.

MATERNITY AND CHILD WELFARE.

THE first annual report has been issued of the Lady Chelmsford All-India League for Maternity and Child Welfare, which was founded by Lady Chelmsford, the late Vicereine of India, in February, 1920. Lady Reading has succeeded Lady Chelmsford as president; she has been indefatigable in her solicitude for the welfare of the women and children of India since her arrival, and has succeeded in obtaining a permanent office for the League. The training of health visitors is carried on at the school established by the League in Delhi, and through it twenty-six students have already passed. Propaganda has taken the form of the sale and distribution of literature and pamphlets, health exhibitions, illustrated lantern lectures, and the publication of the journal of the League, which circulates throughout India and has shown a credit balance on its first year's working. The preparation of a travelling exhibition has been taken in hand. Branches of the League have been established at a number of important centres, and the League has been affiliated with other bodies having similar objects, for its main purpose is to stimulate, assist, and co-ordinate local efforts, and not to supersede them. During the year Madras, Rajputana, and the Punjab formed associations for maternity and child welfare at their capital towns, which became affiliated with the League; welfare centres were also started at Simla, Calcutta, and Dacca. The organizing secretary of the League is Dr. Lilian Wemyss Grant, Delhi.

PLAGUE IN INDIA.

We have received a copy of the report by Dr. A. R. Mehta, medical officer of health for Rawal Pindi, on a re-emergence of plague in that city in the months of October and November, 1921. Rawal Pindi, from the local conditions, is apparently one of the endemic centres of plague in the world, and this epidemic started, like previous ones, in the autumn season in the old grain and fruit market of the city, the infection being propagated both by man and the rat. The preventive measures undertaken by Dr. Mehta included inoculation of a large number of the inhabitants, disinfection and fumigation of the houses, evacuation of the infected houses, rat trapping and baiting, the encouraging of the keeping of cats in the city, and propaganda by lectures and handbills. The outbreak was evidently handled energetically, although some of the measures enumerated are less valuable than others. In the medical officer of health's opinion the housing problem and the provision of rat-proof houses is urgent in Rawal Pindi, but the difficulties are considerable in view of the severe winter which that city experiences and of the mode of living of the general mass of the population. Drastic measures of dealing with the old grain market certainly appear to be urgently required.

England and Wales.

VENEREAL DISEASE ARRANGEMENTS IN LONDON.

THE London County Council, at its meeting on April 11th, considered the arrangements for the diagnosis and treatment of venereal diseases in London during the ensuing financial year. The Council joins with the local authorities of six adjoining counties and three counties in a scheme for the common utilization of the : by certain London hospitals for diagnosis and treatment and laboratory work in connexion therewith. London's proportion of the total expenditure is 82 per cent. It is proposed that this scheme be renewed for the financial year 1922-23. During 1921 the number of patients' attendances under the scheme was 496,209, as compared with 464,033 in 1920, but the number of new cases (25,418) showed a reduction of 5,628. The decrease is ascribed to the disappearance of certain abnormal conditions connected with the war and demobilization and, to some extent, to the continuous anti-venereal campaign. The institutions to which it is proposed to make grants include nineteen general hospitals, ten special hospitals, and seven hostels for the reception of young women during infectivity and of pregnant women and of children suffering from venereal diseases. In connexion with St. Paul's Hospital, premises have been purchased in Endell Street, and a considerable amount spent in adapting them for the purpose of an all-day clinic, with in-patient accommodation for twenty patients, and this, when completed by the early summer, will be one of the most up-to-date institutions of the kind in the country. The Public Health Committee of the London County Council has had its attention drawn to the varying practices of the hospitals as regards the remuneration of the staff engaged on venereal diseases work, and while not suggesting the adoption of a standardized system, thinks it would be desirable to encourage hospital authorities to appoint a whole-time staff, thereby avoiding frequent changes and lessening the expenditure. The Committee is in communication with the Ministry of Health on this question. Another proposed alteration is with regard to publicity and propaganda work. Since 1917 the National Council for Combating Venereal Diseases has been permitted to exercise certain of the Council's powers in this respect. It is now proposed to extend the arrangements for publicity and propaganda work made directly by the local authority, and to discontinue part of this work which has been undertaken by the National Council. The grants to be made for treatment and pathological work at the hospitals amount to £93,100, and the grants for the hostels to £3,600. With possible additional grants for clinics not yet opened and for developments in connexion with rescue and preventive work, the total expenditure under the scheme will be £112,500, as compared with £112,831 for the past year. The amount payable by London is £90,000, of which three-fourths will be recovered from the Treasury. The provision for the past year for publicity and propaganda work was £3,500; this is to be reduced by £1,000. The same amount as before (£5,000) is included in the estimates for drugs.

THE COMBINED HOSPITALS APPEAL.

The Executive Committee of the Combined 1922 Appeal on behalf of the hospitals in Greater London (19, Berkeley Street, W.1) announces that with a view to organizing a campaign in connexion with schools and other educational establishments in Greater London an education branch has been established. Lord Burnham will be chairman of the Central Committee dealing with educational help for the appeal. Mr. E. A. H. Jay, LL.D., a former chairman of the L.C.C. Education Committee, has been appointed director of the education branch. Representatives of the University of London, the different training colleges, the Teachers' Association, the Association of Secondary School Teachers, the Preparatory School Teachers' Association, and representatives of private schools have been invited to a conference on May 9th to discuss arrangements. Donation accounts on behalf of the appeal will be opened on April 18th by some 950 banks inclusive of head offices and branches, in the metropolitan area.

It is now announced that the combined appeal will be for the fourfold purpose of reopening closed beds, meeting the higher costs of materials and re-equipment until prices become more normal, paying off the more pressing debts of

the London hospitals, and securing new subscribers. Steps are to be taken contemporaneously to develop new permanent sources of income by contributory and other schemes. There have already been several conferences with secretaries of general hospitals in London to discuss organization, and another conference will take place after Easter, at which more than a hundred hospitals in all will be represented, and following which the final arrangement will be settled. The Prince of Wales, who is President of the King's Fund, and with whose consent the appeal is being launched, has again cabled wishing it every success.

KING EDWARD'S HOSPITAL FUND.

The annual report for 1921 of the King Edward's Hospital Fund for London states that last year, even more than in 1920, the history of the Fund was bound up with the history of the crisis in hospital finance and the suggested remedies. The King's Fund was asked by the London regional committee of the British Hospitals Association to draw up two schemes, one for a combined public appeal for fresh money to meet present liabilities, and the other for the collection of regular contributions from the hospital-using classes. These two schemes were drawn up and circulated to the different hospitals, but it was not until January, 1922, that they were received back with a definite invitation to the King's Fund to go forward with both. The total receipts for the year amounted to £270,656, of which £18,007 was for capital and £252,659 general receipts. The amount distributed was £220,000, being an increase of £20,000 upon the ordinary distribution of 1920, and was made up as follows. Grants to hospitals—for maintenance, £198,425, for urgent extensions and improvements, £11,575; grants to consumption sanatoriums, £6,070; and grants to convalescent homes, £3,930. In distributing the increased amount available for maintenance the Fund took into the account the efforts made by the hospitals to increase income or reduce expenditure since the emergency distribution in July, 1920, and the issue of Lord Cave's report in June, 1921. Every eligible hospital and consumption sanatorium which applied for a grant was accepted and reported upon, as hitherto, by two of the Fund's visitors, one medical and the other lay. Since the foundation of the Fund a total net amount of £3,816,854 has been distributed, the average annual distribution during the whole period of twenty-five years having been £152,674.

CORONERS' REMUNERATION IN LONDON.

The London County Council granted, as from January 1st, 1921, a temporary addition of £300 to the salary of each of the four whole-time London coroners. This allowance was to continue until March 31st, 1922, or until the Council obtained parliamentary powers to pay fixed salaries to coroners. The attempt to obtain such powers has not been proceeded with, and an application has been made from the four coroners for an extension of the period for which the temporary addition is payable. In view, however, of the fall in the cost of living, and of other circumstances connected with the amount disbursed by coroners, the Council on April 4th decided not to extend the period. The salary of three of the coroners is £1,500 a year, and that of the other £1,186.

Scotland.

"FAITH HEALING" IN ABERDEEN.

A SERIES of remarkable scenes took place in St. Andrew's Cathedral, Aberdeen, on Monday, April 3rd, and the three following days, when Mr. J. M. Hickson, a lay missionary of the Scottish Episcopal Church, inaugurated his Scottish mission for the revival of the gifts of healing, with the approval of the bishop and clergy of the episcopal diocese of Aberdeen and Orkney. Prayer was offered on Monday for invalids unable to be present, suffering from such maladies as heart trouble, spinal curvature, rheumatism, tuberculosis, mental distress, and lupus; and then the laying on of hands was practised on 362 people, four-fifths of whom were women, who had come for healing. On Tuesday the laying on of hands was carried out on 702 men, women, and children, on Wednesday on some 1,400, and on Thursday on over 1,500. In several cases relief was said to have followed, as in that of a woman suffering from chronic swelling of the legs, of another woman who had deafness of many years' duration,

and of a boy with polypus of the nose. It was afterwards stated that the boy had not had polypus of the nose, but had had an operation for obstruction of the nose followed by difficulty in breathing, and it was the difficulty in breathing which had been relieved. Mr. Hickson, who had returned to Britain after a world tour, has gone to Cork to carry on faith-healing mission work there.

RESEARCH IN ANIMAL BREEDING.

Professor Sir Edward Sharpey Schafer headed a deputation on March 5th from the Joint Committee of Research in Animal Breeding of Edinburgh University and Edinburgh College of Agriculture to the directors of the Highland and Agricultural Society, in Edinburgh, for the purpose of urging financial support towards the committee's scheme for research in animal breeding. Sir Edward Schafer said that the reason of the deputation for attending was not only for the sake of getting money; they wished also to get the sympathy and co-operation of agriculturists generally in this matter. They were supported by the Development Commission, and most of the money which they received came from the Development Commission. The Commission, however, had lately laid down the principle that they would only give money if other sums were raised locally. Breeding was a scientific problem, and the principles of that problem were being investigated now in a great many cases, and especially at Cambridge. There were certain definite principles which were being discovered and enunciated, which applied practically to all animals and plants as well. The object of the joint committee was to get those principles first of all determined, and if they had been determined, to investigate for themselves whether they were true, and to get breeders throughout the country to co-operate with them both by bringing their own problems before them, and, still more, by getting them worked out. There had been some attempt made, at this, and Professor Cossar Ewart, in Edinburgh, had succeeded in improving very greatly the quality of the wool in certain sheep as the result of experiments made by him and made to breeders. It had its limitations, but he really stood on the scientific side. They were beginning to see how the discoveries in heredity were going to be applied to animal breeding, and that was really the object of the establishment of this joint committee. They had appointed a director, Dr. F. A. E. Crew, who was only too anxious to co-operate with practical breeders throughout the country in order to get the principles of breeding established.

GLASGOW LOCK HOSPITAL.

Dr. W. G. Dnn presided at the annual meeting of the Glasgow Lock Hospital on March 28th. The report showed that the in-patients numbered 19,516, as against 20,486 in the previous year, while the average age of the patients was 17, as against 17½ in 1920. The financial statement showed that the ordinary expenditure was £7,930; taking ordinary and extraordinary accounts together there was a surplus for the year of £409. A number of improvements had been carried out conducing to the further efficiency of the hospital. In view of the fact that a number of maternity cases occurred in the hospital the directors had decided to have a properly fitted maternity room, and one of the wards was being altered and fitted as such. Dr. Dnn said that there was one paragraph in the report which saddened him very much—the number of young children admitted as in-patients; no fewer than sixty-nine between the ages of 16 and 2 years were treated in the institution. This matter should have the close attention of the directors, and an endeavour made to put the law into force, and if possible to discover the criminals who communicated the disease to these young children. He would recommend to the medical staff and to their legal adviser the close following up of these cases.

THE third annual International Neurological Congress is to meet at the Salpêtrière Hospital in Paris on June 2nd and 3rd; the special subject for discussion is the symptoms of pituitary insufficiency. Drs. Ronssy and Canus of Paris will deal with its anatomy and pathological physiology, and Dr. Froment of Lyons with its clinical and therapeutic aspects.

A SPECIAL sanitary committee of the Japanese Society of Zootechnics has reported that the conditions of milk supply were most unsatisfactory and made the following suggestions: (1) improvement of the quality of the milk; (2) better dairy accommodation; (3) classification according to quality; and (4) control of the price by the direct supply of milk from the farms.

Correspondence.

THE HOSPITAL POLICY OF THE ASSOCIATION.

SIR,—The report of the Conference of Hospital Staffs shows that a considerable minority are opposed to the principle of taking for the medical staff a percentage of the money paid for maintenance "in whole or in part by patients as individuals." May I express a hope that this very contentious principle, of which even its supporters profess themselves ashamed, may reason to be a part of the policy of the Association?

Up till the present I have not seen or heard one valid argument advanced in its favour. The only reason given for its inclusion is that to omit it might lead to abuse. Now ordinary "hospital abuse" by patients who can afford to pay for treatment outside hospital is ruled out; in fact the clause rather cloaks individuals who so abuse hospitals, for under it they can claim that they are paying both the demands of the hospital for maintenance and of the doctor for treatment. The only other abuse suggested is that societies may hand over money directly to insured patients to pay their own hospital fees. Such a course surely could not be taken without detection at an early date. There would have to be a by-law of the society permitting this method of disposal of its funds, and the expenditure must appear on its balance sheet. The abuse must then soon become public and could immediately be checked. I must admit that the clause as it now stands has a logical symmetry and completeness, reminiscent of Schedule D, but recent events have taught us, in Ireland at least, to distrust a remorseless logic and to long for comfortable common sense.

May I say that when we attempt to make our policy operative it is on this point that we shall be most likely to come into conflict with hospital committees, who as regards other classes of patients are already almost convinced of the justice of our demands? It is on this point also that we are likely to lose the sympathy of the public, one of our greatest assets in the past, and we do not want to put into the mouth of some demagogue hereafter the gibe, "When the poor had scraped together a few shillings for the hospital that cured him this is the Association which was not ashamed to grab them." Further, it is on this point that we are most likely to fail in getting the cordial co-operation of the staffs of the larger hospitals, especially of the teaching hospitals. Dr. Cox made only the other week a fine appeal to consultants for their support to the Association. It is not likely to further that desirable end if we insist on living their pockets, and thinly at that, at the expense of their pride or even of their prejudices.

We have declared our adhesion to the principle that our voluntary hospitals should be maintained. Most of them are admittedly on the verge of financial collapse. Does it seem consistent, does it seem politic, to take this opportunity of making a claim on contributions which have hitherto been regarded by everyone as earmarked for the maintenance of these hospitals and for that purpose alone?

One other question. We discussed the payment of hospital staffs in the Hospitals Committee when I was chairman some ten years ago, and we thought then that if hospital staffs were paid per capita, which is practically what our present policy amounts to, hospital committees, being mainly composed of business men, would go into the question on a financial basis, and in most cases would decide that a small whole time salaried medical staff would be cheaper and quite as efficient. That we did not think would be for the advantage of the profession. Perhaps we were wrong, but was the fear groundless?—I am, etc.,

Belfast, April 3rd.

R. J. JOHNSTONE.

SIR,—I have the greatest sympathy with Dr. Garratt and the difficulties he feels and expressed in his letter to you of March 24th, because till 1913 I held the same views as he has so frequently expressed.

The Conference clearly shows that conditions of hospitals differ greatly in the industrial area from those obtaining in London or in the rural areas. In industrial areas events have marched very rapidly in recent years in the manner of them obtaining their support, and it seems to me that when these methods of raising money become applied to other areas (as London is contemplating and as Oxford has recently started with such signal success that it will certainly be copied elsewhere) events will likewise move rapidly there

too, bringing in their train conditions which will make the honorary staffs desirous to modify their present views.

The British Medical Association scheme should be adopted to safeguard the position in the future, even if the staff hand back to the hospital the percentage they receive till these conditions arise.

The recent correspondence in the *Times* had been instructive—apart from the two excellent letters of the Chairman of the Hospitals Committee none have been published except those opposing the scheme—but there is an increasing feeling among the lay committees that the position of hospital staffs has not been just. As a proof of this I venture to send you one paragraph of the annual report of the Leicester Royal Infirmary for 1922, published yesterday:

"The honorary medical and surgical staff have continued to render loyal and devoted service to the institution in the treatment of the patients. Their active co-operation in the administration of the institution has helped the board to conduct the affairs harmoniously and smoothly. In recognition of their loyal services the board are particularly pleased to be able to announce that an arrangement has been made, by a unanimous vote of the board, that the honorary staff shall receive, in the shape of a percentage on certain receipts coming to the institution arising from national or municipal sources, a small recognition of their valuable services. The board are unhesitatingly of the opinion that this arrangement will cement the good relationship which has always existed between the honorary staff and the board."

I should have craved the hospitality of your columns ere this (as I much desired to enter the literary fray on this subject) had I not felt that the recording of facts when they had become accomplished was far more potent than the airing of my opinions.—I am, etc.,

Leicester, April 6th.

ASTLEY V. CLARKE.

P.S.—Readers may have noticed an advertisement in the *JOURNAL* of April 1st by the Leicester Royal Infirmary containing the words: "The Infirmary has adopted the 'Staff Fund' policy as suggested by the British Medical Association." This is, I believe, the first such, and marks a new epoch in voluntary hospital management.

SIR,—The plea of Mr. Harman in favour of the plan to eject almost all patients from Class A is that, great extension of hospital services being inevitable, it is essential at once to "stake out a claim" on behalf of their medical staffs; that the modern workman scorns charity; that staffs who decline to accept the Staff Fund can give it back or apply it to altruistic purposes; and finally, that, having committed ourselves to the Leicester motion in 1920, we are bound to support it now.

The first essential in "staking out a claim," if you would not be warned off by the police, is to show good title to the ground, and this Mr. Harman conspicuously fails to do. There is no justification for the appropriation by medical men of funds collected by laymen from laymen for purely lay purposes, neither is there precedent in the recognized customs of medical practice for the claiming of commission on money spent on food, light, firing, and similar items of maintenance. Next, if workmen despise charity, they must found and maintain hospitals for themselves. Even the patients in the "private" class, unless they pay outside nursing home rates, are undoubtedly receiving charity. To pretend that the "tariff" class are not recipients of charity to a considerable degree degrades the hospital below the level of a provident dispensary, and its staff beneath the status of the more generously salaried officers of such an institution. The third argument is equally mischievous. If this money is honestly earned, it is impertinence to suggest what each man does with his own, while to give it back at once implies that it is not honestly earned, and places it in the same category as "conscience money" returned by persons guilty of cheating the revenue officer. I would ask Mr. Souttar, who now considers himself a robber of the rich, whether, when he has reduced the number of his free patients in hospital by 75 per cent., he proposes to make similar reduction in his private fees, and if not why not? While to Dr. Wyatt, who claims that all but the destitute should pay something to him, I would remark that even a "sixpenny doctor" would hesitate to exact a fee from one who could afford but 2s. 6d. a week towards the bare necessities of life, and hitherto we have not placed ourselves on a lower plane than these.

As for the fourth argument of Mr. Harman, in 1912 the profession embarked on a mad adventure which led to a most humiliating defeat. Applying the argument adduced, because we were exceptionally foolish in 1912, therefore we should

behave similarly in 1922. Indeed there is risk of this. It is futile to attempt by threats of resignation to coerce lay boards of hospitals. All they need do is to reply, "Unlike you, we have nothing to lose, we will resign too." And what should we do then? Mr. Harman is singularly reticent on the question of how many boards have accepted the Leicester motion. The only board that has done so to my knowledge is that of the Leicester Royal Infirmary, whereon sit paid delegates of trade unions, who report to these unions. The possibilities of abuse of their power by paid representatives of a powerful and wealthy union are obvious moreover, this practice is the negation of voluntary management. I would far rather serve in State or municipal hospital than one liable to trade union control. The abolition of voluntary staff service must lead to paid managers, and State, municipal, trade union, or approved society control. Therefore I would beg all to consider carefully whether amendments on the lines suggested in my letter of March 11th¹ are not the utmost limit that any staff that would retain the title "honorary" can demand, or any self-respecting honorary lay board can be expected to concede. They are a compromise between the policy of the Scottish hospitals on the one hand and that of the British Medical Association on the other, are based upon principles intelligible to the public, and have therefore a reasonable chance of acceptance by laymen, which cannot be said of the Leicester motion.—I am, etc.,

Chichester, March 30th.

G. C. GARRATT.

SIR,—At the conference of members of staffs of voluntary hospitals recently held, as also in your reference thereto in this week's issue of the JOURNAL, it is stated that recommendation 33 is the Leicester resolution several times previously affirmed.

From the point of historical accuracy, and to prevent confusion later, might I be allowed to point out that this recommendation is a Brighton resolution sent in in January last for consideration by the Annual Representative Meeting at Glasgow. This has evidently been brought to the notice of the Hospitals Committee, approved by that body and the Council, and in favour of it the Leicester resolution has been jettisoned.

The Brighton resolution (now No. 33) will have a rider attached to it which is very much alive, and will no doubt be placed before the Annual Representative Meeting in July. This Division considers the rider will meet many objections to No. 33. It is to the effect that when the staff of a voluntary hospital is advised that the payments by any patient are derived solely from that patient and that the financial position of that patient is such as to render him unable to pay more than the full cost of maintenance, the staff should refuse to accept any portion of these payments.—I am, etc.,

L. A. PARRY,

Hove, April 4th.

Honorary Secretary, Brighton Division.

REDUCTION OF MEDICAL FEES.

SIR,—It was not to be expected that Dr. Ellis's proposal would be popular; nevertheless I believe it is proper that the profession should consider the question of the readjustment of the 50 per cent. increase in fees which was adopted in the latter part of 1919. It may be that on careful examination of the conditions it would not be found advisable to make any alteration at present; although the cost of living and of practice are still much more than 50 per cent. above pre-war rates, they are certainly less than they were when this advance in fees was made. Conditions in practice are now in so many ways altered from what they were before the war that it probably would be well for the profession to discuss the whole question of fees in private practice; these are probably in many instances even now too low; in other instances it is quite reasonable to think that they should be somewhat reduced. A large number of patients who in years past were willing and accustomed to pay fairly good fees now find it difficult to pay any fees at all, much less to pay 50 per cent. more. It must be recognized that where patients expected three or four visits they now often, because of the cost, object to more than one, and in many instances, if at all possible, do without any medical attendance, so that the economic value of the 50 per cent. increase is, to say the least, doubtful.

This reconsideration of fees, if and when it takes place, must have regard not only to the different classes of patients but to the different areas of practice, and the matter must be

¹ BRITISH MEDICAL JOURNAL, p. 414.

dealt with by the profession as a whole, for, although fees were at first raised in individual practices and in detached areas, the action of the Council in recommending a minimum increase of 50 per cent. made it practically the policy of the Association, and it might, and probably would, now be considered disloyal and hardly honourable for isolated individuals to lower their fees, or any part of their fees, without the general consent of the profession; in fact, if such action was started in even a few instances the results might well be disastrous. I am particularly anxious that the initiative should come voluntarily from the profession itself; if we were forced by public opinion to make any change the result could not be so satisfactory, and our position would certainly not be dignified.

There is ample time for any Division to consider this question and lay proposals before the Representative Meeting in July.—I am, etc.,

Bradford-on-Avon, April 8th.

CHAS. E. S. FLEMING.

ROUTINE PELVIMETRY IN ANTE-NATAL CASES.

SIR,—I have read Dr. Foss's letter of April 8th, criticizing mine of March 25th, with much interest. Dr. Foss "views with surprise" the fact that I rely principally on the external conjugate, and states that he uses the intercrystal and interspinous measurements to determine the variety of pelvis present. I have followed more or less carefully the English literature on pelvimetry for the last twenty years, and I cannot remember a single modern authority upholding Dr. Foss's opinion; in fact, most experts agree that the intercrystal and interspinous measurements are "of little value—in fact, scarcely worth the trouble of recording. . . ."

"The more important measurements are those of the true pelvis, and of these the external conjugate probably gives the most information" (Dr. A. W. Bourne, of Queen Charlotte's and St. Mary's Hospitals; see BRITISH MEDICAL JOURNAL, January 18th, 1919). On the other hand, it is quite possible that I have not seen some important papers on this subject upholding Dr. Foss's views, and if so, I should much value his reference to them. If, on the other hand, Dr. Foss bases his assertion solely on his own experience I am afraid we shall have to agree to differ. Dr. Foss has the advantage over me in that his medical training is very recent and hence modern, and if he has been taught to rely on the intercrystal and interspinous measurements I should be much obliged if he would state his authority. The subject is one of great interest and importance.

With regard to the estimation of the diagonal conjugate, though I always seek to obtain it, I rarely succeed, as in the ordinary pelvis it measures 4½ inches, and as Dr. Herman said, "the finger is only about 3 inches long, and if you get near the promontory so much pain is caused by the knuckles pressing up the perineum that the patient will probably object" (BRITISH MEDICAL JOURNAL, June 30th, 1906).—I am, etc.,

Woking, April 8th.

R. THORNE THORNE.

THE CLOTHING OF NATIVES IN RELATION TO TUBERCULOSIS.

SIR,—In reply to Dr. J. S. Pearce's inquiry in the JOURNAL of March 25th, asking if there are any medical reports regarding the wearing of clothes by aboriginal natives being a cause of tuberculosis among them, I would refer him to the report of the Commission appointed by the Governor-General of South Africa to inquire into the prevalence and spread of tuberculosis in South Africa (1912-14), of which I was chairman. I believe a copy of the volume is to be found in the library of the British Medical Association. But in any case I shall be pleased to lend the book. The belief that the use of European clothing is partly responsible for the spread of tuberculosis among the native races is fairly widely held by those Europeans who have an intimate knowledge of the native in his kraal. Its influence, however, can only be of the nature of a predisposing or contributory cause. The primary cause of tuberculosis among aboriginal natives is infection by the European, but once introduced into a native community it spreads rapidly on account of the unhygienic habitations and the extremely dirty communal habits of the native, and also because of his great susceptibility to the disease. His susceptibility is probably due both to an inferior racial power of resistance, and to the absence of that acquired protection which the great majority of Europeans obtain as the result of mild tuberculous infections (often bovine) in very early life. In considering the effect of

clothes-wearing, the fact must not be overlooked that European clothing usually connotes the association of the native with Europeans; and also the adoption of some of the European's habits and vices; among which are alcoholic intemperance, the adoption of unsuitable food, and unhealthy occupations. Nevertheless, in itself the wearing of clothing may influence the spread of tuberculosis, because (a) it is generally cast-off European clothes; (b) it is usually of unsuitable kind; (c) it is worn continuously without change, often day and night, and is, generally speaking, very filthy; and (d) no difference in dress is made for variations of temperature, nor is it removed when, as often happens, it becomes soaked with rain or sweat.—I am, etc.,

Torquay, March 28th.

A. JOHN GREGORY.

A DIPLOMA IN TUBERCULOSIS.

SIR,—Evolution in medical practice is marked by a growing tendency towards specialization. At one time it was considered sufficient to have physicians, surgeons, and general practitioners. Later alienists, obstetricians, and gynaecologists detached themselves, followed by oculists, aurists, and throat and nose, skin, rectal, urinary, venereal, and other specialists, all covered by their university or college diplomas. As time went on such diplomas were considered insufficient, and extra ones, such as the diplomas in public health and tropical medicine, were added. Now it is proposed to have still another, a diploma in tuberculosis. Where is specialization to end? It is surely enough to have departmental specialization without proceeding to specializing in single diseases. Every consulting physician is, or ought to be, a specialist in tuberculosis, and easily know all that is known about it. Also, it would soon be found necessary to specialize still further. There would arise specialists in pulmonary tuberculosis, in tubercle of the brain and spinal cord, in abdominal, osseous, glandular tuberculosis, etc.

The medical treatment of tuberculosis is extremely unsatisfactory. Fresh air and the *vis medicatrix naturae* seem to be the only reliable agents. The hypodermic injection of auto-serum has been found of benefit in surgical tuberculosis and may be found equally useful in medical cases. It seems futile to devote time and effort to attempted cure while at least one known and preventable cause is neglected: very many cases of tuberculosis, especially of the abdominal type, are due to the ingestion of milk secreted by cows suffering from tuberculosis. It is the imperative duty of the State to forbid the sale of milk from tuberculous cows. All cows ought to be examined by veterinary surgeons, and only those certified free from tuberculosis should be permitted to supply milk for human consumption.

If another diploma is really called for, one in parasitology should commend itself. It may be too sweeping an assertion to make that all disease is due to the action of parasites, but it is a fact that the part which parasites play in the genesis of disease is not, by any means, fully realized. If all diseases due to parasites were excluded from medical works the latter would be extremely short and pleasantly cheap, while treatises on tropical diseases would be non-existent.—I am, etc.,

Driffeld, E. Yorks, March 26th.

A. T. BRAND, M.D.

SLIPPING RIB.

SIR,—In the case reported under this heading by Dr. H. K. V. Soltan (BRITISH MEDICAL JOURNAL, April 1st, 1922, p. 516), there was no displacement of the tenth costal cartilage, the pain being localized to the tip of the eleventh rib. It might likewise be worth recording that, in the early nineties, I had under observation several out-patients, chiefly females, suffering from "pain in the side," and in each of them I was able to trace it to the tip of the tenth or of the eleventh rib. In the absence (so far as I knew) of any mention of this clinical condition in our medical literature I applied to it the name "rib-tip tenderness." This was a strictly symptomatic designation, not limited to any one of the different etiological varieties yet applicable to all of them. As such it might still serve a useful clinical purpose as a reminder to examine the costal cartilages in all cases of pleurodynia, some of which are by no means easy to identify conclusively as of pleuritic, gastric, or cardiac origin, or as purely nervous or "neurotic." A systematic examination for undue rib tenderness could hardly fail to detect the abnormality of an unattached tenth cartilage and of its liability to develop the condition of slipping rib.—I am, etc.,

London, W., April 5th.

WILLIAM EWART.

DIABETES MELLITUS: A SUGGESTION.

SIR,—Having been a sufferer from diabetes mellitus for over twenty years (since about 20 years of age), I have naturally taken great interest in the subject, especially in new lines and treatment. During these twenty years science has much advanced, many discoveries been made, and many theories advanced and applied, only to fail in practice.

That most in vogue at the moment—the fasting treatment—seemed to offer much promise, but when examined carefully and its results compared with the ordinary cases regulated by diabetic dietary, it will be found that the final result is about equal as far as time of death is concerned, especially in cases that have been treated for some time by ordinary methods. It may therefore be asked why a patient should be subjected to continued underfeeding and his life thus made miserable. Better admit the failure of the modified Allau treatment at once and inform all sufferers. To have a sugar-free urine is excellent from a scientific point of view, and speaks volumes for the skill displayed in London hospitals to obtain this result. But how is it obtained? Not by correct diagnosis, for the cause of diabetes mellitus has yet to be discovered; therefore sugar-free urines have been established by haphazard lucky shots.

The chemistry of the blood and urine will serve to differentiate the various forms of diabetes and settle the question whether the pancreas is affected or not. All this is estimable, and is gradually narrowing down the number of probable causes.

Recently a much more hopeful line of investigation has arisen—that is, the bacteriological. The right line was struck by Sir W. H. Willcox when he said that the true cause was damage to the pancreas by some toxic agent. As I do a little bacteriological work myself this interests me immensely, and I hope some day to hear that the germ causing this malady has been isolated and a suitable antigen discovered. I live in expectation of this. *Staphylococci*, *pyorrhoea* (*Treponema mucosum*, Noguchi), *B. coli*, and other well-known microbes can be dismissed as only occasional causes. The possible line of investigation, to my mind, should be to search carefully the ports of entry to the system, by way of the alimentary tract more especially, and to cultivate all bacterial flora of the stomach, duodenum, jejunum, pancreas, and colon. The specimens should be obtained aseptically at operation or immediately after death, using many kinds of media, classifying all bacteria found and their proportions, special attention being paid to unknown varieties, their isolation and inoculation into animals. This appears to me to be the most suitable way of seeking to discover the true cause of diabetes mellitus. It is one upon which research is only just beginning.—I am, etc.,

Bognor, Feb. 18th.

J. F. REX.

AFTER-RESULTS OF COLECTOMY.

SIR,—In taking part in the discussion which followed the reading of Sir Berkeley Moynihan's paper on the after-results of colectomy, I made certain statements which are clearly open to misinterpretation.

In criticizing the inadequate statement of results as "good," "fair," or "bad," the last person I had in mind was Sir Berkeley himself, for in his communication he had given all the data which the most captious of critics could demand. I need only add that I am indebted to Sir Berkeley Moynihan for giving me most of the opportunities I have had of investigating the pathology of intestinal stasis, and that I have the utmost admiration for his work.—I am, etc.,

ARTHUR KEITH.

Royal College of Surgeons of England,
April 8th.

PROSTATIC ENLARGEMENT.

SIR,—In his letter on prostatic enlargement, published in the BRITISH MEDICAL JOURNAL of April 1st (p. 539), Mr. T. E. Hammond utters a warning against the adoption of such palliative measures as organotherapy when once the symptoms and signs of enlargement are present. He rightly states that the existence of a relationship between enlargement of the prostate and some change in the endocrine system is too problematic to form a basis of treatment by organotherapy, and that a course of organotherapy might be tried in early cases, but not when once an operation is indicated.

Whilst agreeing entirely with the tenor of Mr. Hammond's remarks, I do not think that his fears lest palliative measures

¹ P. J. Cammidge, BRITISH MEDICAL JOURNAL, October 29th, 1921, p. 733.

should be substituted for radical ones are justified, or that my remarks on the relationship of the prestate to the endocrine glands are likely to encourage attempts at organotherapy when operation is indicated. Suprapubic prostatectomy is such a satisfactory and successful operation that, if anything, the tendency is to have recourse to it in cases in which it is not strictly indicated, rather than to neglect it in those in which it is.

When the history of prostatic surgery comes to be written the same criticisms will be levelled at the operation of suprapubic prostatectomy that must be levelled at other successful operations, such as gastro-enterostomy. The very success of the operation has resulted in its having been employed at first without that discrimination and judgement that have afterwards been attained.

I quite agree with Mr. T. E. Hammond's remark that palliative measures should never be employed "when once operation is indicated." The point on which we may not entirely agree is as to when an operation is indicated. Moreover, when once operative measures are decided upon, is caeculation necessarily the only procedure? Although the number of cases suitable for the adoption of such partial operations as "forage" is a small one, I am convinced that these measures have a real, if restricted, place in prostatic surgery. Mr. Hammond does not mention such procedures in his letter, but I take it that he does not include them in what he terms palliative measures.—I am, etc.,

London, W., April 8th.

KENNETH M. WALKER.

RESTRICTION OF INFLUENZA EPIDEMICS IN SCHOOLS.

Sir,—In their comments upon our notes on "The restriction of influenza epidemics in schools by the use of local prophylactic vaccines," Drs. Cameron and Billing have, we think, made too much of the idea that we claim to have proved the beneficial results of the administration of a vaccine by the means of a single set of figures submitted, whereas we have ourselves devoted a paragraph in our short article pointing out the difficulties of a fair interpretation of our own statistics.

We hope that, before long, you will allow us space in your columns to publish another article, which we have now in preparation, dealing with the same question, which we consider is far too important and too difficult to be settled except by the collection and comparison of statistics taken under different circumstances and covering a larger range of observations.—We are, etc.,

Rugby, April 5th.

A. I. SIMEX,
J. W. H. EYRE.

The Services.

ROYAL NAVY MEDICAL CLUB.

THE annual dinner of the Royal Navy Medical Club will take place this year at the Trocadero Restaurant (Balmoral Room), on Thursday, April 27th, at 7.30 for 8 p.m. Members who wish to be present are asked to inform the Honorary Secretary, Royal Navy Medical Club, 68, Victoria Street, S.W.1, not later than seven clear days before that date.

TERRITORIAL DECORATION.

THE Territorial Decoration has been conferred upon the following officers under the terms of the Royal Warrant, October 13th, 1920:—*Royal Army Medical Corps*: Colonel William Coates, C.B., C.B.E., V.D., Honorary Colonel, East Lancs Division; Colonel E. A. Wraith, C.B.E., D.S.O., A.D.M.S., North Midland Division; Lieut.-Colonel C. I. Ellis, C.M.G., D.A.D.M.S., 43rd (Wessex) Division; Lieut.-Colonel P. G. Williamson, M.C., attached 5th Battalion West Yorkshire Regiment (ret.); Major Angus MacGillivray (ret.); Major T. H. Richmond, O.B.E., attached North Midland Brigade, R.F.A. *Sanitary Companies*: Captain J. Grounds, 1st London Sanitary Company.

DEATHS IN THE SERVICES.

SURGEON-MAJOR ISAAC NEWTON, Bengal Medical Service (retired), died at Cheltenham on March 28th. He was born on January 9th, 1838, the son of Dr. Isaac Newton, of Knaresborough, and was educated at Leeds and Paris; he took the M.R.C.S. in 1859, and entered the I.M.S. as assistant surgeon in the same year. He became surgeon-major in 1873, and retired in 1877. He served in civil employ in the Punjab, where he was successively civil surgeon of Dalhousie and superintendent of vaccination. He was the author of a small work on vaccination.

Obituary.

SIR PATRICK MANSON, G.C.M.G., M.D., LL.D., F.R.S.,
Consulting Physician, Seamen's Hospital Society; late Medical
Adviser to the Colonial Office.

With deep regret we announce the death, on Sunday last, April 9th, of Sir Patrick Manson, whose name is closely associated with one of the greatest advances ever made in medical science. He was the son of John Manson of Pingsh, Aberdeenshire, where he was born on October 3rd, 1844. He was educated at Edinburgh and at the University of Aberdeen, where he graduated M.B., C.M. in 1865 and M.D. in the following year. He spent the early part of his professional life in the East. After practising for some time in the island of Formosa he went to Amoy, one of the chief ports of China; there he was in charge of a large native hospital. Later he moved to Hong-Kong, where he took a leading part in the foundation of a College of Medicine for the Chinese. Besides lecturing on medicine he filled the office of dean of the institution, and had a great influence on its development. On his return from the East he settled in London. In 1893 he became a Member of the Royal College of Physicians, and was elected a Fellow in 1895. He joined the medical staff of the Seamen's Hospital Society in 1892; when he retired from active service in 1912 he was appointed consulting physician, and retained his position as senior teacher in the London School of Tropical Medicine.

Very soon after his arrival in the East, Manson had his ignorance of tropical diseases forcibly brought home to him. In an address delivered at St. George's Hospital, and published in the *British Medical Journal* of October 9th, 1897, he gave an account of these unpleasant but enlightening experiences. When he went to Formosa he knew nothing about beri-beri save its name, and naturally failed to recognize the disease when it came before him. The patient was a Chinese clerk employed in a European firm. Manson found him sitting propped up in a chair, short of breath, dropsical from head to foot, with a cardiac bruit, irregular tumbling action of the heart, and a feeling of distress in the chest. Thinking the case was one of heart disease he prescribed what he considered suitable remedies, but when he called next day expecting to find an improvement, the patient was dead. Some years later he saw a number of Chinese soldiers in hospital suffering from what appeared to him to be locomotor ataxy. He declared that although there was no immediate danger to life they would not recover. In defiance of this prognosis some of them in a short time were walking about and others had even returned to their military duties. A good many, however, died suddenly just like the Formosan patient. Manson found no help in his books. He noticed that, whereas some of the patients were wasted to shadows, others were swollen and oedematous. In most of them the muscles, especially those of the calf, were tender. As the Chinese are very fond of pork he thought he might be dealing with an outbreak of trichinosis, but he found no trichinae in the muscles. It was not till months had elapsed and a good many deaths had occurred that he recognized that he was confronted with an epidemic of beri-beri.

In Formosa he encountered elephantiasis, but could find no satisfactory solution of the problem it presented. Later in Amoy he saw many more forms of the disease, but the riddle of causation still remained unanswered. During a visit to London in 1874 he heard for the first time of the discovery made by Timothy Lewis in 1872 that in the blood of a proportion of the inhabitants of certain districts of India was to be found an organism which he called the *Filaria sanguinis hominis*. These parasites Lewis had met with in more than one case in association with elephantiasis or elephantoid diseases. On his return to China in 1876 Manson discovered that these parasites were present in some districts in 10 per cent., and in others in 50 per cent., of the population, whilst in some places they were not found at all. As the organism showed no evidence of growth while in the blood, or any features warranting the supposition that it was capable of reproducing itself, the inference was that it was an immature form. After much search he found that this was the case, although the discovery had been anticipated by Bancroft as well as by Lewis. The problem how the organism gained access to the human body had next to be solved, and it occurred to Manson that as it was never found in any of the natural discharges, it could not escape spontaneously so as to pass from one man to another without the aid of a carrying agent capable of penetrating the skin and absorbing the blood. It struck him that

the most likely agent in the translation of the filaria was the mosquito. To determine the frequency with which that parasite was present he examined the blood of a thousand natives, with the help of two Chinese medical students he trained for the task. These assistants were occupied in hospital, one working in the daytime, the other at night. While the one who worked at night brought many positive results, the other seldom found a filaria. Investigating this point, Manson found that in ordinary conditions of health the organisms appeared in the blood about sunset, gradually decreasing towards morning. This filarial periodicity suggested an adaptation of the habits of the parasite to the nocturnal habits of the mosquito, and Manson set to work to find out whether the filaria was ingested with the blood which the mosquito had imbibed, and, if so, what changes occurred; he was able to see that, so far from killing the filaria, the digestive juices of the mosquito seemed to have stimulated it to fresh activity. After many months of work he succeeded in tracing the parasite through the stomach wall into the abdominal cavity and thence into the thoracic muscles of the mosquito. During this passage the filaria increased enormously in size and developed a mouth, an alimentary canal, and sexual organs. Manson conjectured that when the mosquito died the little organism it contained escaped into water and by that path reached the human body. With better appliances he tried later on in England to trace the exact route by which the filaria left the mosquito. He obtained infected insects from Dr. Bancroft of Australia, and Dr. Low of the London School of Tropical Medicine succeeded in making sections which showed the filaria in the act of passing through the proboscis of the mosquito and entering the body through the bite. It was thus proved that certain kinds of mosquito are carriers of this filaria and are agents in transmitting the diseases to which this parasite gives rise. By systematic examination of the blood of natives of many tropical countries Manson discovered blood-haunting larval filariae of three other specifically distinct nematodes—namely, *Filaria loa*, *F. perstans*, and *F. demarquayi*. The embryos of the *F. loa*, the eyeworm of tropical West Africa and its hinterland and the cause of the "Calabar swellings" so common among Europeans in those regions and so often mistaken for erythema nodosum, resemble very closely those of *F. bancrofti*. They differ, however, in minute anatomical details and also in having an exactly opposite periodicity; they enter the general circulation in the daytime and disappear from it at night. This circumstance led Manson to suggest that the liberating and intermediary host must be a biting insect such as the mangrove fly (*Chrysops dimidiata*). This suggestion was proved to be correct by Leiper.

This pregnant discovery of the transmission of an agent of disease by intermediary agents soon led to developments of the highest importance to mankind. For thousands of years malaria had levied a heavy tribute of human life and turned many a fertile and thickly peopled region in India, Africa, and Europe into a barren wilderness. In his *Malaria*, published in 1827, Macculloch traced the influence of the fell disease in the degeneracy of the race in Italy, Sicily, France, Spain, Holland, and America, and W. H. S. Jones, in his *Malaria and Greek History* (1909), contended that it played a large part in bringing about the decadence of Greece. It was the great obstacle to the colonization of tropical territories by the white man. To the discovery of the cause of this scourge Manson applied the knowledge of the conveyance of disease by insects gained from his researches on filaria. The theory of the insect-borne origin of paludal fever was not altogether new, but the faint adumbrations of modern doctrines by old writers had been forgotten when, in 1880, Laveran announced that, working in Algiers, he had found the parasite which is the cause of malaria. The importance of the discovery was not appreciated at the time, nor was the nature of the organism determined or the significance of its various phases ascertained. Laveran's statements were, however, confirmed by Richard in Algiers, Osler in America, and in Italy by Golgi, who worked out the morphological features of the tertian and quartan parasites and the schizogony or the sexual phase. Further advances in our knowledge of this part of the life-cycle of the malarial parasite were made by Celli and Marchiasava, but here for the time progress ceased. Except as far as it afforded an invaluable guide in diagnosis and treatment Laveran's discovery remained barren for more than a decade. It gave no clue to prevention; it did not explain how infection was conveyed nor throw light on the peculiar geographical and local distribution and limitation of the

disease. Malaria continued to be the dragon which guarded the golden apples in the garden of the Hesperides. To slay this monster Manson came forth armed with the spear of knowledge and with unconquerable enthusiasm. In a paper on the nature and significance of the crescentic and flagellated bodies in malarial blood published in this JOURNAL on December 8th, 1894 (p. 1306), he pointed out how closely parallel the conditions of the evolution of the filaria are to those of the plasmodium. At that time the so-called "agony forms" of the parasite were generally looked upon as indications of a state preceding the death of the parasite in blood withdrawn from the body. Manson, on the other hand, reasoned that as the malarial parasite, like the filaria, was incapable of leaving the body by its own effort, being enclosed in a red corpuscle, therefore some blood sucking animal which frequents the haunts of malaria might be the agent in transmission. For epidemiological as well as biological reasons he became convinced that the mosquito was the intermediary of the malarial parasite as he had shown it to be of the filaria. He was unable for want of material to test the hypothesis, and he could not afford to spend the necessary time in a malarious country. In the hope that someone with better opportunities might take up the search, he published a summary of his views in the BRITISH MEDICAL JOURNAL of December 8th, 1894. A sum of money was promised by the British Medical Association to enable him to go to British Guiana on condition that the Royal Society would grant a similar amount, but the plan was not carried out, and the task passed on to the capable hands of Major (now Sir) Ronald Ross, who began to work on the lines of the theory on his return to India in 1895. At first Ross had bad luck in some of his stations and at one time had to give up the search. Manson suggested that in default of human subjects he might work out the life-history of the corresponding parasites in birds which closely resemble those in man. Ross succeeded in tracing the bird parasite into the mosquito's stomach, thence into the salivary glands, down the proboscis, and back again into the bird. It was then proved that the same thing applied to the human being, and after Ross had established this Grassi, Bigami, and Bastianelli showed by what species of anophles in Italy malaria could be communicated to man. Italian scientists also succeeded in communicating malaria to man by mosquitos which had fed on a person suffering from malaria. After a certain time these insects were fed on other men free from malaria and these in due course got the disease. But the theory met with opposition and ridicule, and for a time it seemed to be destined to the fate of Carlos Finlay's discovery of the part played by *Stegomyia calopus* in the causation of yellow fever. The neglect of that suggestion cost many thousands of lives in Havana alone between 1881, when the discovery was announced, and 1901, when it was confirmed by Reed, Carroll, Agramonte, and Lazear, and measures founded on it put an end to yellow fever in that haunt of the disease. The story of the work done in India by Ross in the face of official indifference and active obstruction, how he overcame all obstacles and brought his quest to a successful issue, is known to all the world. The story was told by Manson in the third of the Goulstonian lectures on the life-history of the malarial germ, delivered before the London College of Physicians in March, 1896, and published in this JOURNAL on March 28th, 1896 (p. 775).

In a discussion at the Geographical Society in 1898 on the possibility of acclimatization of Europeans in tropical countries (BRITISH MEDICAL JOURNAL, April 30th, 1898, p. 1168), Manson stated that 99 per cent. of tropical diseases are caused by germs which in their extracorporeal stage are very vulnerable. In the Huxley lecture, delivered at Charing Cross Hospital in the same year, he said that besides malaria he could adduce many illustrations of the conveyance of disease by intermediary agents both from human and from veterinary pathology; he instanced yellow fever, African tick fever, trypanosomiasis, filariasis, and certain kinds of spirochaetiasis. Manson held that we were justified by analogy in conjecturing that the same principle also applied to many similar protozoal germs whose life-history had not yet been fully determined.

Ever since his return from the East Manson had pleaded for the provision of systematic instruction in tropical diseases. Some attempts had, indeed, previously been made here and there to supply teaching in tropical pathology. In the plan of a medical school drawn up by Dr. Benjamin Golding, the founder of Charing Cross Hospital, in 1822 the necessity for lectures on tropical diseases is expressly mentioned. In

1856 Dr. Felkin established in the Edinburgh Extra-Mural School a course of lectures on diseases of the tropics and climatology. It is claimed for Edinburgh that this was the first regular course of lectures of the kind delivered at any medical school in Europe or America. On Felkin's retirement the course was continued by Dr. Andrew Davidson. In February, 1899, the University of Edinburgh established a lectureship in diseases of tropical climates, and provided for a course of practical instruction in parasitology and bacteriology. In 1899 a similar lectureship was established in Aberdeen, and was held by Dr. G. A. Macdonald, who had for twenty-five years been connected with the Grant Medical College of Bombay. The first lectureship on tropical medicine in London was established at St. George's Hospital in 1895; Manson was appointed to the post, which he held till 1908, when he resigned. In 1893 a similar lectureship was instituted at Charing Cross Hospital, and to it Manson was appointed. All this marked some degree of progress, but it was inadequate for the purpose. Manson felt that what was required was a school fully equipped with a teaching staff, a hospital, and laboratories for practical instruction and research. Many difficulties had to be overcome, but fortunately Manson became medical adviser to the Colonial Office, and in that capacity was brought into association with Joseph Chamberlain, then Secretary of State for the Colonies, a statesman of large vision who perceived the vast importance of medicine in colonization. Through his influence with Chamberlain the scheme which Manson had so much at heart was brought to fulfilment. He had already given an outline of it to Mr. (now Sir James) Michelli, Secretary of the Seamen's Hospital Society, in 1896, and on April 27th, 1898, Manson was able to announce to the Geographical Society that an endeavour was being made to establish a school for the training of doctors who intended to practise in our tropical colonies. In the following year came the realization of his dream. With the whole-hearted co-operation of Chamberlain the London School of Tropical Medicine was opened at the Victoria and Albert Docks on October 2nd, 1899. An account of its foundation and development was given in the BRITISH MEDICAL JOURNAL of February 7th, 1914 (p. 321). A school on similar lines had been established at Liverpool in April, 1899, under the auspices of the late Sir Alfred Jones. The generous rivalry between the two schools has been a powerful factor in the progress made in this country in the knowledge of tropical diseases and the means of combating and preventing these scourges. They have been a model for similar institutions in various foreign countries; in France schools were founded in Paris, Bordeaux, and Marseilles. An Institut für Schiffs- und Tropenkrankheiten was founded in 1900 at Hamburg, and a Belgian State school was established at Brussels in 1906. Others have been established in India, Italy, and the United States.

Not only did Chamberlain take no active part in the foundation of the school, but he placed a sum of money at Manson's disposal to enable him to bring his malaria theory to a conclusive test which should carry conviction to every reasonable mind. With this object he sent out to the Roman Campagna, the most malarious part of Italy, a small expedition, the members of which undertook to live among the fever-stricken population, and to expose themselves all day to the sun, wind, and rain, and the emanations from the soil, retiring for the night before sunset to a special house where they were completely protected from mosquito invasion by wire gauze netting. A complementary experiment was to be made on getting mosquitos which had fed on malarial patients sent from Rome, and making them bite persons in London who had never had malaria. Both experiments were entirely successful. Drs. L. W. Sambon and G. C. Low and an artist, Mr. A. J. Terzi, with some friends lived in the Roman Campagna in the height of the fever season for many months without contracting the disease. On the other hand, a son of Manson and a laboratory assistant at the London School of Tropical Medicine, who allowed themselves to be bitten by the imported mosquitos, had fever two weeks afterwards, and the parasites were found in their blood. This was the *experimentum crucis* which finally settled the question of the causation of malaria.

Manson's career is a striking illustration of the good work that can be done amidst the difficulties and worries of general practice by an energetic man away from any scientific centre with nothing but his own enthusiasm to encourage him and with only the most rudimentary appliances to work with. In the early part of his career, besides the struggle for

existence, he had a tropical climate to contend with. At home he had more formidable difficulties to encounter in the discharge of his mission as the apostle of what was a new gospel not only in medicine but in the development of the empire. He met with chilling indifference and even active hostility. But, happier than most scientific pioneers, Manson lived to see the triumph of the cause which he had so strenuously advocated, and the school of which he was the true begetter grew before his eyes from small beginnings to an institution of imperial importance.

One of his last public appearances was when he visited the school in its new building on January 20th last to receive a portrait subscribed for by a large number of past and present students of the school and other friends at home and abroad. At the same time it was announced that money had also been subscribed for a medal bearing Manson's portrait to be awarded annually to a pupil of the school distinguishing himself in clinical medicine. Manson was an inspiring teacher and had a racy, virile style that impressed students and attracted many distinguished visitors from foreign countries. He was popular with his pupils and was generous in help to all who sought it. He contributed largely to the literature of his special province. His principal work was *Tropical Diseases: Manual of Warm Climates*, published in 1898, republished twice in 1900, twice in 1903, and again in 1917. It was translated into French by Manrico Guiland and Jean Brengués in 1904. In conjunction with Daniels he wrote the articles on beri-beri, and, in collaboration with Shipley and Sandwith, those on parasitic worms, sprue, lath, and aishnm in Allbutt and Rolleston's *System of Medicine* (1907), and articles on *Filaria sanguinis hominis*, etc., in Quain's *Dictionary of Medicine*. In 1896 he delivered the Goulstonian lectures at the College of Physicians, taking as his subject the life-history of the malaria germ outside the human body; the course was published in the BRITISH MEDICAL JOURNAL. The introductory address at St. George's Hospital, in which he urged the need for the systematic teaching of tropical pathology, was delivered in 1897; and later on (1905) he gave also the Lane lectures at San Francisco, the subject being tropical diseases.

Among Manson's other writings are papers on leprosy and other subjects in the *Medical Reports Chinese I.M. Customs Gazette* from 1871 to 1884; he wrote many papers on the *Filaria sanguinis hominis*, and finally brought all his results together in a monograph on the *Geographical Distribution, Pathological Relations, and Life-History of Filaria sanguinis hominis diurna and of Filaria sanguinis hominis perstans in connexion with Preventive Medicine* (1893). One of his last contributions was an important survey of recent discoveries in tropical medicine and hygiene, which he contributed to the British Medical Association's volume, *British Medicine in the War, 1914-17*; it was also published in the BRITISH MEDICAL JOURNAL of July 28th, 1917. Manson's scientific output was large and varied. But perhaps his best monument is the school which is the concrete expression of the ideas of which he was the fervent apostle.

Honours came in abundance to Manson. In 1900 he was made a C.M.G., in 1903 he was advanced to K.C.M.G., and on his retirement from the post of medical adviser to the Colonial Office in 1912 the King bestowed on him the honour of Knight Grand Cross of the Order "in recognition of his eminent services in connexion with the investigation of the causes and cure of tropical diseases." His own University of Aberdeen conferred on him the honorary degree of LL.D. in 1896, and the University of Oxford that of D.Sc. in 1924. He was elected a Fellow of the Royal Society in 1900. He was also a foreign Associate of the Paris Académie de Médecine. In 1911 an international committee was formed for the purpose of presenting him with a gold medal bearing his effigy. The medal, which was designed by Dr. Paul Richier of Paris, who is eminent as an artist as well as a physician, was presented to him at the International Medical Congress held in London in 1913.

In 1875 he married Henrietta Isabella, daughter of Captain J. P. Thurburn, R.N. By her he had two sons—one of whom, Philip Thurburn, a member of the medical profession, died in the East in 1902—and three daughters, one of whom married Dr. Philip Manson Bahr.

Manson was a devoted disciple of Izaak Walton, and at one time used to fish in Scotland every year. In recent years he deserted the rivers of his native land for Ireland and took a place at Clonbur, co. Galway, where he indulged his sport to his heart's content. After his retirement from practice he retained his interest in the Tropical School and usually spent

Professor Boyd was elected assistant physician to the Edinburgh Royal Infirmary in 1899, and he also acted as one of the physicians to the Deaconess Hospital of the Church of Scotland, becoming consulting physician to that hospital in 1913. Soon after his appointment to the staff of the Royal Infirmary he had his first experience of war service, going as he did through the South African war as physician to the Edinburgh and East of Scotland Hospital. He obtained honourable mention in dispatches, and was decorated C.M.G. in 1901. In 1901 he became major R.A.M.C. *à la suite* of the 2nd Scottish General Hospital, and when the great war began in 1914 he was mobilized and served first at Craigleith and later at Bangour (Edinburgh War Hospital). In 1917 he went to France as lieutenant-colonel in charge of the medical division of a general hospital; after his return from France early in 1918 he proceeded to Egypt and Palestine as colonel A.M.S. and consulting physician to the British army there. His work there occupied a year; he was again mentioned in dispatches, and was created a Companion of the Bath (Military Division) in 1919. Meanwhile (in 1913) he had been appointed to the senior staff of the Royal Infirmary; and in 1919, on the retirement of Professor William Russell (at age limit) Dr. Boyd was appointed Moncrieff-Arnott Professor of Clinical Medicine in the University of Edinburgh. He threw himself at once into the work of reorganizing his department after the war conditions had passed, and succeeded therein to a notable degree. Had he been spared for another ten years of active work his influence on the progress of clinical medicine in his university would indeed have been far-reaching and profound. Besides acting as examiner for the Membership of the Royal College of Physicians he was formerly a member of the Board of Examiners for entrance to the Indian Medical Service, and he

was principal medical officer to the Standard Life Assurance. He was joint editor of the Report of the Edinburgh and East of Scotland Hospital in South Africa, and he contributed to the *Edinburgh Medical Journal* "Experiences of a consulting physician on duty in the Palestine lines of communication" (1919). Amongst his recent contributions to medicine was one on "Pellagra" in 1920.

Professor Boyd was held in high estimation by the undergraduates who followed him in his wards, and he was greatly appreciated also for his post-graduate teaching. He was always clear and inspiring, was eminently sane in his judgments, and both in the infirmary and as a consultant in private practice he was consequently highly regarded and much sought after. Of his engaging social qualities and love of sport those who knew him best speak most highly, and he acted with the greatest acceptance as the secretary to the Octogenarian and joint secretary to the Harveian Dining Clubs. To his friends his death is a supreme loss, as may be gathered from Professor Alexis Thomson's tribute printed below; and the whole profession in Edinburgh mourns his passing, as was shown by the large gathering in the Dean Cemetery on the afternoon of April 7th, when what was mortal of him was consigned to mother earth. He was married in 1904, and leaves a widow and two daughters.

We are indebted to Professor ALEXIS THOMSON for the following appreciation:

Francis Boyd's friends feel his loss deeply, too deeply for words; the personal loss overshadows that which they recognize has been sustained by the school. One of his merits was that he appeared younger than his years; the writer recalls the spring golfing parties at Sullom, years and years ago, guests of the late Sir John Batty Tuke, who prided himself on selecting among the younger generation of medicos those who combined an interest in sport with the possession of brains and the capacity and intentions of using them. Tuke deserves credit for recognizing this combination; six of the eight guests became university professors, and the remaining two leading teachers and specialists in the medical school. While capable, as above suggested, of relaxing upon occasion, Boyd could bury himself in his work and stick to it as hard as any man; good sportsman as he was, he liked nothing better than his work. He also had the strength of character that combines so well with industry and ambition; his victory over a bad stammer, which had appeared likely to dissipate any hope of academic distinction, was an apt illustration of his strength of will, for, as a teacher, his diction left nothing to be desired. As a doctor, those who knew him best liked him most; he never assumed what is traditionally known as the bedside manner; as a consultant he was admirably thorough and reliable, perhaps carrying reserve to excess, and therefore, from the patient's point of view, addicted to fewer words than were desired. The social side of his character was that which appealed most to his intimates; as secretary of the Octogenarian and joint secretary of the Harveian Dining Clubs he shed his natural reserve and showed himself in his most attractive colours—one of the most genial and kindest-hearted of men. His absence will be greatly felt at their annual gatherings.

Dr. THOMAS FREDERICK HIGGS of Dudley died on April 2nd, in his 87th year. He was educated at Dudley Grammar School and Sydney College, Birmingham, and took the Diplomas of M.R.C.S.Eng. in 1858, L.R.C.P.Edin. and L.S.A. in 1860; he graduated M.D.St. Andrews in 1884. In 1860 he purchased a practice in Dudley, where he remained till his death. After serving as a district medical officer under the board of guardians he became medical officer of the workhouse, a post which he retained for forty-eight years, when he was appointed honorary consulting medical officer. He was appointed surgeon to the Dudley and borough police in 1862 and continued to hold that office, and was also senior honorary surgeon to the Dudley Dispensary. He took great interest in local educational affairs, was a member of the first school board for Dudley, and as a trustee of the Wesleyan Day School was subsequently co-opted on the Education Committee as a representative of the voluntary day schools. He was one of the founders of the Dudley High School for Girls and deputy chairman of the Dudley Grammar School board of governors. He also served for nearly a decade on the Dudley Town Council. Dr. Higgs, who was a Justice of the Peace, was a member and late chairman of the Dudley Division of the British Medical

Association, and chairman of the Medical and Panel Committees of Dudley. He is survived by three sons and four daughters.

Mr. THOMAS TURNER, F.R.C.S., J.P., of Hereford, died recently at the advanced age of 92. He was born in June, 1830, and received his medical education at University College Hospital, taking the diplomas of L.S.A. in 1854 and M.R.C.S.Eng. in 1855; he became an F.R.C.S.Eng. in 1891. After qualifying he remained for some time as demonstrator of physiology under the late Professor Sharpey, and later took up his residence in Hereford as junior partner with the late Mr. Charles Lurgin. Until his final retirement in 1919 he was never out of harness and rarely had a holiday. In 1856 he was elected to the staff of the Hereford Dispensary, and in 1863 he was appointed surgeon to the Hereford Infirmary, retaining the latter post until he reached the age limit in 1900, when he was elected to the honorary consulting staff. In the old days he was a keen Volunteer, and retired with the rank of surgeon-major. For three years he was a councillor and for twelve years an alderman on Hereford Town Council, and he was appointed a Justice of the Peace for the borough. He married the daughter of his former partner, but she predeceased him, and he had no children. By his skill, his quiet, genial, and unassuming manner he was a general favourite in Hereford, and retained until the last the place of that city and county's most trusted and popular consultant.

Dr. ROBERT BAIN LOTHIAN died in Glasgow on March 30th. He was a native of that city; his father was the late Dr. John A. Lothian, who for twenty-two years was surgeon to the Glasgow Royal Infirmary. Robert Lothian was educated at Glasgow University, where he graduated M.B., C.M. in 1888. After acting as house-surgeon at the Royal Infirmary and studying for a time in London he returned to Glasgow to join his father in practice. In 1896 he was appointed casualty surgeon to the northern police district, and in 1902 he transferred to the central division, where, in addition to acting as casualty surgeon, he lectured on ambulance work to the police force and fire brigade. During the war he served in the R.A.M.C., retiring with the rank of captain. He was chairman of the Re-survey Boards of the Ministry of Pensions, Glasgow area. For many years he held a prominent place among the medical profession in Glasgow, where his loss will be greatly felt.

Universities and Colleges:

UNIVERSITY OF CAMBRIDGE.

Diploma in Psychological Medicine.—A short course of instruction for the D.P.M. examination will be held in Cambridge from July 12th to August 17th. The course will include lectures and practical work on psychology, the anatomy and physiology of the nervous system, morbid psychology, mental diseases, dreams, mental deficiency, etc. The fee for the full course is twelve guineas. Further particulars may be obtained from the Secretary, D.P.M. Committee, Psychological Laboratory, Cambridge.

UNIVERSITY OF LONDON.

At the meeting of the Senate on March 22nd the Vice-Chancellor referred to the death of Dr. Augustus D. Waller, F.R.S., and said that on behalf of the Senate he had addressed a letter of sympathy to Mrs. Waller and her family on their bereavement, and had deputed Sir W. H. Wilcox, chairman of the Physiological Laboratory Committee, to represent the University at the funeral. The following were recognized as teachers of the University in the subjects and at the institutions indicated:

London Hospital Medical College: Mr. G. E. Neligan and Mr. W. S. Perrin (Surgery), Mr. F. F. Muecke, C.B.E., and Mr. N. Patterson (Oto-rhino-laryngology).

Middlesex Hospital Medical College: Mr. H. Charles (Anaesthetics), Mr. H. Watson Turner (Dental Surgery).

It was resolved to institute a University Readership in Biology tenable at Middlesex Hospital Medical School at a salary of £200; applications to be received by May 15th.

The status and designation of appointed teacher were conferred on the following:

St. Thomas's Hospital Medical
(Professor of Pathology), Professor
Professor F. G. Parsons (Professor
(Professor of Morbid Anatomy).

Dr. H. W. Lyle, Dean of King's College Hospital Medical School, has been appointed a Fellow of King's College.

Professor W. D. Halliburton has been appointed a member of the board of examiners in physiology at the second examination for

medical degrees, Part II, for the remainder of the year 1921-22, in place of Professor Bainbridge, deceased.

Lord Dawson of Penn has been appointed a representative of the University at the seventh centenary celebration of the University of Padua to be held in May.

The annual service at Westminster Abbey will be on presentation day, May 4th, at 5.45 p.m. Applications for tickets, accompanied by a stamped addressed envelope, should be sent to the honorary secretary, Miss E. Jeffries Davis, 88, Gower Street, W.C.1.

Applications for grants from the Thomas Smythe Hughes Medical Research Fund to assist in original medical research must be sent in not earlier than May 1st and not later than June 15th. Further particulars can be obtained from the Academic Registrar.

The Lindley Studentship, value £120, will be awarded to a student qualified to undertake research in physiology in the Physiological Laboratory of the University. Statements of qualifications and of mode of proposed research must be sent to the Academic Registrar (from whom full regulations as to the award can be obtained) by May 1st.

A University Studentship, value £50 for one year, will be awarded to a student qualified to undertake research in physiology tenable in the Physiological Laboratory of the University, or of a school of the University. Applications must be sent to the Principal Officer (from whom further particulars can be obtained) by May 31st.

UNIVERSITY COLLEGE.

A course of four lectures on "Insects and disease" will be given at University College, London (Gower Street, W.C.1), by Sir Arthur Shipley, G.B.E., F.R.S., Master of Christ's College, Cambridge, on Tuesdays, May 2nd, 9th, 16th, and 23rd, at 5 p.m. The syllabus of the lectures is as follows: (1) Lice, their habits and life-history and their relation to disease; (2) bed-bugs and ticks as conveyers of disease; (3) flies and the way they cause and carry disease; (4) mosquitos and malaria. The lectures are addressed to advanced students of the University and others. Admission is free, without ticket.

The annual report of University College, London, states that the new building for anatomy, histology, and embryology, provided by the Rockefeller gift, has been begun, and that it is expected to be ready for occupation in March next year. The expenditure of the College on establishment account in 1921 was £150,482; the fee revenue provided £65,567. After reckoning incomes from endowments, donations, and grants from the Treasury and other public bodies, there remained a deficit of £5,185. There are, moreover, several directions in which the expenditure ought to be increased; thus an income of £15,000 a year is needed by the Department of Applied Statistics to carry on the work contemplated by its munificent founder, the late Sir Francis Galton. Capital funds to the amount of £15,000 are needed for the new chemistry laboratories.

During the year the total number of students enrolled was 3,143 (1,835 men and 1,308 women). Of these, 2,408 (1,505 men and 902 women) were taking day courses; 502 (191 men and 311 women) evening courses; 233 (138 men and 95 women) vacation courses. The day course students included 432 (326 men and 106 women) post-graduate and research students. Of the total, 212, including 76 post-graduate and research students, came from various parts of the Empire—India sending 50, Canada and New Zealand 8 each, Australia and South Africa 4 each; from European countries there were 324—59 from France, 50 from Russia, 40 from Sweden, 36 from Switzerland, 25 from Holland, 24 from Norway, 23 each from Belgium and Denmark, 14 from Italy. There were 16 from the United States of America, 10 being undergraduate and 6 research students. From other countries the largest number (23) came from Japan, of which 14 were doing post graduate and research work.

QUEEN'S UNIVERSITY OF BELFAST.

In publishing (April 1st, p. 544) the list of successful candidates upon whom the degrees of M.B., B.Ch., B.A.O., were conferred, it should have been stated that the following had passed their examinations with second-class honours: A. H. McC. Eaton, W. S. Gibson, W. Lascelles, Mary C. Lindsay, I. H. McCaw.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary comitia of the Royal College of Physicians of London was held on Monday, April 10th, at 5 p.m., the President, Sir Norman Moore, Bt., being in the chair.

The President announced that after four years of office he did not wish to serve for a further year. He then gave a summary of the chief events in connexion with the College during the past year, and referred in detail to the ten Fellows of the College who had died during the year—Dr. G. D. Longstaff, Sir George Savage, Dr. Albert S. F. Leyton, Dr. F. A. Bainbridge, Dr. John Wickham Legg, Dr. John Harley, Dr. John Elliott, Dr. George Charles Bright, son of the celebrated Dr. Richard Bright, Dr. Ainslie Hollis, and Sir Patrick Manson.

Sir William Church proposed a vote of thanks to the President for his address and for his services to the College during the past year. Sir Norman Moore then vacated the chair, and the College proceeded to the election of a President. In the first ballot Sir Humphry D. Rolleston received 34 votes and Sir John Rose Bradford 17, 81 Fellows voting. In accordance with the by-laws of the College a further ballot took place, when Sir Humphry Rolleston received 58 votes, Sir John Rose Bradford 23.

Sir Humphry Rolleston was inducted President by the senior Fellow present, Sir W. S. Church. He then gave his faith to the College.

Various communications were received; and Sir Humphry Rolleston was appointed the representative of the College at the celebrations in honour of the seventh centenary of the University of Padua.

After a proposal by Dr. Sidney Phillips in regard to the Finance Committee of the College, the President declared the comitia closed.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY council was held on April 6th, when Sir Anthony Bowlby, President, was in the chair.

Votes of thanks were given to Mr. Alban Doran for his valuable services in continuing to arrange and catalogue the collection of surgical instruments in the Museum; and, also, to the Government of Trinidad for presenting to the College some skeletons excavated at Pale Secco.

Lives of the Fellows.—A report was received from the Library Committee stating that the *Lives of the Fellows of the College* had been completed. The work was carried out by the librarian, Mr. Plarr, and although only in manuscript, it is hoped at some future time to have it printed and offered for sale.

The Jacksonian Prize was not awarded. The subject for the year 1923 is "The pathology and treatment of malignant disease of the testicle."

Charles Brook (Lincoln) and William Coates (Manchester) were elected Fellows as Members of twenty years' standing.

Congratulations were sent to a College centenarian, Dr. C. H. Brooking of Paignton, who became a Member in 1843.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates passed the examination of this school held at the termination of the sixty-eighth session (January to March, 1922):

* R. W. Cilento (winner of "Duncan" medal), * J. H. Andre, * Major G. C. Dunham (U.S. Army), * E. A. Mills, * G. Giglioli, * T. G. Wynne, * J. B. Kirk, D. F. G. Moore, Captain H. Hingston (I.M.S.), W. H. Parcock, Major B. Gato (I.M.S.), B. L. Joshi, E. S. E. Mack, R. T. Carr, M. S. E. Mody, Captain J. M. R. Hennessy (I.M.S.), H. C. V. Joy, G. B. Walker, V. M. Fisher, W. H. Grace, G. G. Naecker, M. A. El Nattan, D. R. Melita, Miss E. G. Baillie, J. J. B. Edmund, Miss M. L. Griffiths, A. Noble, Captain C. A. Wood (I.M.S.), C. Clynch, Miss H. M. Brown, A. N. El Ramli, Miss L. S. Pigeon, A. Razik, J. G. B. Brass, J. A. Griffiths, J. S. Kerr, E. F. Peck.

* With distinction.

Medical News.

THE next session of the Dental Board of the United Kingdom will commence on Tuesday, May 9th, at 2 p.m., when the chairman, Right Hon. F. D. Acland, M.P., will take the chair and give an address; it will continue to sit from day to day until the termination of its business.

At the meeting of the Harveian Society, to be held at the Town Hall, Harrow Road, Paddington, on Thursday, April 27th, at 8.30 p.m., a discussion will take place on influenza. The speakers will be: Sir Humphry Rolleston, Sir Thomas Horder, Dr. Sidney Phillips, Dr. R. A. Young, Dr. Thoresby Jones, Dr. Beaumont, Dr. Freeman.

A FURTHER series of demonstrations of specimens in the Museum of the Royal College of Surgeons of England will commence on Friday, April 21st, when Sir Arthur Keith will demonstrate specimens of hernia, the femoral and obturator forms, and the causation of hernia. The demonstrations, which are open to advanced students and medical practitioners, take place at 5 p.m., and will be continued on Mondays and Fridays up to and including May 8th.

A MEMORABLE evening was spent by some five-and-twenty former assistants and residents of Emeritus Professor Sir Halliday Croom on April 7th, when they had the pleasure of entertaining their old "chief" to dinner at the North British Station Hotel, Edinburgh. To mark the occasion of his retirement last year from the Chair of Midwifery in the University of Edinburgh and the completion of fifty years of teaching in the Edinburgh School of Medicine, a silver salver with a suitable inscription and the engraved autograph signatures of fifty former assistants and residents was presented to Sir Halliday by the chairman, Dr. Haig Ferguson. The health of the guest was proposed by the Chairman, and the toast was supported by Dr. George Mackie, D.S.O., and Dr. George Gibson, D.S.O. Sir Halliday Croom replied in a speech full of most interesting reminiscences of his career as a teacher of midwifery and gynaecology, delivered in his happiest vein. Among those present were Dr. Godfrey (Searborough), Dr. Hale Puckle, Dr. Scott Macgregor (Glasgow), Dr. Duncan Main (Manchuria), Dr. Donald (Carlisle), Dr. Aarons (London), Dr. Lamond Lackie, Dr. William Fordyce, and Dr. R. W. Johnstone (Edinburgh); letters and telegrams of apology and regret were received from such distant parts as Montreal, Egypt, and New Zealand.

At the last meeting of the Council of the Royal College of Surgeons of England (reported on another page) congratulations were sent to Dr. C. H. Brooking, of Paignton, on attaining his hundredth birthday. Dr. Brooking was educated at Guy's Hospital, and took the diploma of M.R.C.S.Eng. and the L.S.A. in 1843; he graduated M.D. at St. Andrews in 1856. He formerly practised at Brixham, and is one of the last of the Volunteers of 1852; he commanded the Artillery Volunteers at Brixham in 1859. It is stated that Dr. Brooking is the oldest medical practitioner in England.

A PORTRAIT in oils of Dr. H. H. Aitclison has been presented to the Corporation of Wallsend in recognition of his public services. Sir G. B. Hunter, in unveiling the portrait in the Council chamber, traced the development of Wallsend, and paid tribute to the large part played by Dr. Aitclison in the life and work of the district. The Mayor, in accepting the portrait, also testified to the worth of Dr. Aitclison and the esteem in which he is held.

IN connexion with the ceremony of dedicating the Osler Hall, erected in Queen's Park, Toronto, as an auditorium for the Academy of Medicine, Sir Edmund Osler has presented the academy with a portrait of his brother, the late Sir William Osler.

THE members of the Surgical Union, a union of provincial surgeons, the members of which are limited in number, visited the urological departments at King's College Hospital on April 6th. The morning was spent in attending two short lectures, followed by a lantern demonstration in the medical school. The members then saw a number of cases of cystoscopy and fulguration (treatment of bladder growths in the out-patient department, and then spent some time in the radiographic department, where cases of pycnography were demonstrated. In the afternoon operations were performed on urological cases. The visitors were received by Sir John W. Thomson Walker.

THE Maternity and Child Welfare Group of the Society of Medical Officers of Health have postponed the meeting fixed for April 20th until May 18th, when Dr. R. C. Jewesbury will read a paper on "Breast feeding." The Metropolitan and Home Counties Sub-Group will meet as arranged on April 26th at 5.15 p.m. Dr. H. C. Cameron will open a discussion on "Vomiting in infancy: its meaning and treatment."

A COURSE in advanced oto-rhino-laryngology will be held at the Saint Joseph Hospital, Paris, under the direction of Dr. Georges Laurens, from April 28th to June 24th; the number of places is limited to ten, and the fee is 150 francs.

THE three societies of mental medicine at Paris have decided to organize a meeting on May 30th and 31st to commemorate the centenary of the thesis in which Bayle first described general paralysis. The meeting will be international. The subscription of 40 francs should be sent to Dr. Raymond Mallet, 284, Boulevard St. Germain, Paris.

A MEDICAL congress on accidents to workmen was recently held at Zaragoza, Spain. The Minister of Labour and the Rector of the University presided, and among the resolutions adopted was one to the effect that hernia should be regarded as entitling to two months' wages or an operation at the expense of the employer, and also that diseases contracted in hospital as a complication of an accident or contagion and death from the operation should be grounds for compensation.

DR. V. EICKEN has succeeded Professor Killian in the chair of oto-rhino-laryngology at Berlin.

THE Dutch Central Society for combating Tuberculosis recently sent out forms of inquiry. Answers were returned to 40 per cent., reporting 16,259 cases of tuberculosis (7,190 in males and 9,069 in females). As so many circulars were not answered the actual number of cases of tuberculosis is not known, but it is estimated that some 6,000 or 7,000 persons are in need of sanatorium or hospital treatment.

An account of the scheme of medical relief initiated in Russia by the American Relief Administration is given in a recent report by its medical director, Dr. Henry Beeuwkes. Dr. Beeuwkes and his assistants, who number eleven, have made a complete survey of health conditions and hospital facilities, and have drawn up a comprehensive relief plan which is already operating in Moscow, Petrograd, Kazan, Simbirsk, Samara, Saratov, Tzaritzin, Ufa, and Orenburg. "I know of no class in Russia," Dr. Beeuwkes writes, "more deserving of our admiration and assistance than the medical profession. A large percentage have died during the last three years from epidemic diseases to which they have been constantly exposed. Under-nourished and overworked, assuming the labours of their comrades who have succumbed, their weakened physical condition has made them a ready prey to infections, and their mortality rates are out of proportion to those pertaining generally. The mortality rate among physicians from typhus is reported to be 50 per cent. as against 15 per cent. for the general population."

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CONTRIBUTORS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

Telephone, 100, Central.

QUERIES AND ANSWERS.

"I. D." asks for the name and maker of an efficient bed lift to run the patient on his bed, on to a terrace, for fresh-air treatment.

"RHEUMATIC" asks for information as to any spas in the Austrian Tyrol where treatment could be obtained for rheumatic fibrositis of hip and thigh muscles.

"BAFFLED" asks for suggestions in the treatment of the case of a professional gentleman, aged 44, who has for many years been much troubled by offensive breath. The tongue, never clean, has a coating of a brown-yellow colour, partly, perhaps, the result of pipe smoking. The teeth have been very carefully overhauled and pronounced guiltless. The bowels are regular, there is no nausea or vomiting, the appetite is fair, and dieting has been of no avail. Physical signs are negative, the lungs and nasal passages are healthy, the urine normal, and there are no headaches. Many remedies have been tried without benefit. The patient refuses to submit to a test meal, as he had an alarming experience on a previous occasion.

INCOME TAX.

"F.A.C." inquires as to the allowance due for expenses of replacement of car on the following facts: In 1914 he bought an 11.9 second-hand Belsize for £165, which he sold in April, 1921, for £170. He then purchased an 11.9 second-hand Phoenix Coupé, £450, and this he sold in November, 1921, for £230 and bought a new 11.9 Morris Oxford Coupé for £180.

* The expense allowable on the first replacement, assuming the two cars to be of the same grade and condition, would be £450 - £170 = £280, or, allowing for the additional expense of the Coupé to-day, say £250, less any further allowance for the superior condition of the Phoenix as compared with that of the Belsize in 1914. So far as the second replacement is concerned the amount that can be claimed is the excess of the cost of a Phoenix (of same condition as that in which the car was bought in April) in November, 1921, over £230.

"C. C." earned a fee in 1920 and showed it on a declaration made for purposes of repayment. He is now being applied to by a local collector for payment of tax on the fee. Is he justified in refusing payment?

* Yes; assuming, of course, that the untaxed fee shown on the declaration was taken into account in calculating the amount repaid. There may be a technical liability if "C. C." received a formal notice of assessment and did not lodge an objection within the prescribed time, but we can hardly imagine that claim being pressed in the circumstances.

"X." keeps one maid-servant solely for practice and appointments.

* In those circumstances the money wages and also the cost of keep and accommodation—say at the rate of 15s. a week—can be deducted as a professional expense.

"SHIP'S SURGEON" was serving out of the country from February 22nd, 1921, to March 27th, 1922, except for a period of three weeks, between voyages, when he acted as locum tenens.

* Our correspondent appears to be liable to British income tax on the amount of his earnings less the usual allowances, and less deductions for any special expenses, such as the additional cost of uniform, if worn.

"A. W." has a resident assistant, who is of course not liable to account for tax on the value of the board and lodging received by him in kind; for this reason the local inspector is refusing to allow "A. W." to reckon the cost of that board and lodging as a professional expense.

* * The inspector has no legal justification for refusing the claim. The cost in question is clearly an allowable expense in "A. W.'s" accounts, and whether the assistant is liable for tax thereon or not is a question which in no way concerns "A. W." In the leading case of *Tennant v. Smith* which established the non-liability of benefits received in an inconvertible form the point in issue was the value of the free residence of a bank manager; he was held not liable to tax on the value of that benefit, but it was not disputed that the bank could treat the whole of the rent paid for the premises as a business expense.

LETTERS, NOTES, ETC.

MEDICAL BOOK-KEEPING.

DR. F. ARTHUR HEPWORTH (Saffron Walden) writes: "Seeker's" inquiry on this subject leads me to recommend the system of book-keeping, which is saving me much time and labour and which I find infinitely simpler than the old one—comprising day-books, ledgers, and cash-book—of my earlier experience. I use a card system for individual records and accounts, and a cash-book showing receipts on the left hand page and expenses on the right page. No day-book is kept and no ledger. The card system consists principally of white cards, size 7 inches by 5, having the patient's name and address at the top and ruled in four columns for date, particulars of case, treatment, and cash. The second column contains particulars of consultation or visit, and any clinical details which I wish to remember. Under treatment I enter prescriptions and a record of anaesthetics, operations, instrumental aid at confinements, electrical or massage treatment, articles supplied, or any other special details which are to be charged for in the last column. Fees are entered in black ink, cash payments in red ink, and when an account is paid the payment is entered in red and a red line ruled across the card. The amount paid is also entered in the cash-book at the same time. In the case of single patients this completes the booking. The whole account can be seen at a glance, and any account asked for can be made up at a moment's notice. All cards are filed in alphabetical order, subject only to the modification required to keep those for members of one family together. In the case of a family also, I file a pink ledger card in front of the group of individual cards. This ledger card contains only the totals for each quarter or half year transferred from the individual cards. This represents the whole of the posting required.

The keeping of the cash-book is important. Every amount received or paid is entered at once. The book I use is of the analytical type, having seven columns on each side. I have separate columns for private fees, panel payments, appointments like pensions' referee and life assurance, consultation fees, etc., and on the expenses side, separate columns for motor expenses, drugs, rent and taxes, and so on. The sixth column is reserved for payments and drawings on the bank, and should correspond exactly with the bank pass-book. This column can with advantage be signed in red ink. The seventh column is of course a summary of the other six.

The cash-book can be balanced on any day of the year, it can be checked by the bank pass-book, and the financial condition of one's practice can be ascertained at any time without difficulty. It is hardly necessary to say that the pass-book for my practice is separate from that for my private account.

It has been claimed that the time taken in finding a required card and in filing cards at the end of a busy evening is a serious drawback to the use of a card system. I find that this loss of time is more than compensated by the time saved in looking up old references in ledger and day-book, and by having the whole of a patient's history and cash account before me at each consultation. The time saved in posting and in making out quarterly accounts is enormous. For purposes of audit the cash-book, pass-book, and file of receipted bills are all that are required. By having the books audited once a year all the requirements of income tax inspectors, or a possible future purchaser of the practice, can be satisfied.

DR. D. J. COCHRANE (London, N.W.8) writes to recommend the "Physician's Ledger and Record," which he obtained in the first place from Canada, renewals being supplied through Messrs. H. J. Ryman, Ltd., 49, Great Portland Street, W.1.

Several other correspondents are to be thanked for supplying particulars of bookkeeping methods in reply to the inquiry.

SUICIDE IN BORDERLAND CASES.

DR. P. H. WALKER (Mquanduli, Cape Province) writes: An considerable number of suicides follow a moral lapse of some kind with inability to face the consequences, or occur in the course of illness such as typhus, enteric, or pneumonia; in certain classes of society the friends may try to bluff it out that it was an accident and deny premonitory symptoms, but in most cases the subsequent inquiry elicits, with little variation, a story of noticeable alteration of manner or mental depression without real cause for it, and, further, that no doctor was called in. That is all we get generally, there were closer observation it would

probably be recorded oftener that the depression appeared to have lifted just before the end. For Dr. Luke's case in your issue of January 28th is perfectly typical. In the prodromal stage the patient may not only show, but admit to, mental depression; a highly intelligent patient may even say—I am not safe here, I ought to be under restraint; but when the real insane stage begins he declares he is now recovered, he may appear better physically, and he is now far too cunning to say anything that could be put in a lunacy certificate.

It is going too far to say that every melancholic is a potential suicide. It would greatly simplify matters if it were true. But any melancholic may be a potential suicide, and to be wise before the event would require omniscience. As I have said, however, generally no doctor is called in, and so his prescience is not tested. When it does happen that the patient is in his doctor's hands, with the uncertainty of prognosis, apart from the danger of future legal proceedings, where would two medical men be found to agree during the prodromal stage that the patient should be certified as likely to become a danger to himself? If not certified, but persuaded to become a voluntary boarder or a hostel guest, he walks out like Dr. Luke's patient, when he becomes really insane. Hostels and half-way houses are all very well for neurotics and trivial cases of unbalance, but for the real thing they are obviously useless.

HERPES AND VARICELLA.

DR. R. E. SCHOLEFIELD (Blackheath) writes: As hearing on the discussion of the relation of herpes zoster and varicella which has given rise to much correspondence in your columns, the following case may be of interest to other readers:

On February 27th I was called to see an elderly man, about 70 years of age, who two days before had been attacked by severe pain in his right temple, sufficient to prevent his sleeping for that night. The pain was of a burning and stabbing character, and shooting through his head. The next day he noticed spots on his brow, and on the following day, when I saw him, he had a marked eruption of vesicles from the eyebrow well up to the vertex on the right side, which in places was confluent. The content of the vesicles was slightly haemorrhagic in places, in others serous. The left brow and side of scalp was free, except for one tiny spot, but over the trunk and inside the mouth were numerous vesicles, some full, and some in process of scab formation, and some just coming out, those on the trunk showing the oval zone of erythema so typical of varicella. The temperature was 100° and there was some malaise. In the next twenty-four hours a few more spots came out, and then all began to dry into the scabs seen in varicella and herpes alike. It was impossible to trace any source of infection, and as no children were in the house no further case has been seen.

There are three possible explanations of the phenomena: (1) Varicella and herpes occurring in the same subject and coming out together; (2) varicella, with an unusual distribution, and with three-quarters of the spots on the distribution of a single nerve; (3) herpes pure and simple with herpetic generalized eruption. Personally I am inclined to the third explanation. Herpes has been known to exhibit the character of an infectious disorder, and epidemics in a hospital ward are not unknown. This being so, the case would be on a par with that of a generalized vaccinia following vaccination; of which I saw an example in an adult during the war, a very unusual but not impossible event. If any of your readers have seen cases bearing on the point, and making explanations (1) and (2) more likely, I should be glad to know the details.

FIRST AID TO THE INJURED.

THE Chief Secretary of the St. John Ambulance Association writes: I notice in your issue of April 8th that attention has been called to the title of the present edition of our first-aid textbook. It is quite true that the original manual was written by the late Surgeon-Major Peter Sheppard, and subsequently rewritten by Dr. R. Bruce. The present manual, however, is not based on that work.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 27, 29, 30, 31, 32, and 33 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 28 and 29.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

350. Babinski's Reflex.

RUDOLF (*Journ. of Neurol. and Psychopath.*, February, 1922) discusses the phylogenetic significance of the plantar response in man. The reflex was tested on a large number of animals for purposes of comparison, when it was found that the normal plantar response is of the plantar flexion type in lower animals, whereas in the primates it is of the dorsiflexion or extensor variety. In the human infant there is a period, consisting of the first week of life and to a certain extent the second also, in which a flexor plantar response is often present; but this infantile flexor response changes later into the normal extensor plantar response of the child. This change need not occur in both feet simultaneously, and female infants obtain the extensor plantar response at an earlier period than males. The same primitive flexor response may occur in certain cases of total transection of the adult human cord. Therefore as the animal scale is ascended the type of response varies, for the lower creatures give no response at all, the higher an extensor reflex, whilst adult man gives a flexor plantar response. There is a similar succession of flexor, extensor, flexor in the development of the average individual, for the infantile flexor response changes to the extensor response of the child, and this again to the normal flexor result of the adult. The last is an indication of the highest degree of evolution, in which greater control over the lower centres of the cord is exercised by the brain. These observations lend support to the view that the extensor plantar response of infants and of spinal lesions in man is an atavistic phenomenon dependent on the prehensile toe of our arboreal ancestors.

351. Infective Endocarditis.

PARSONS-SMITH (*New York Med. Journ.*, February 15th, 1922) classifies infective endocarditis into three clinical groups: (1) associated with acute and subacute rheumatism; (2) as a factor in the process of an acute pyæmia; and (3) as secondary to the reinfection of a quiescent lesion. Diagnosis is frequently extremely difficult, since the clinical picture may simulate such other diseases as septicæmia, typhoid, acute miliary tuberculosis, or meningitis; but, associated with evident heart mischief, pyrexia, splenic enlargement, pallor, clubbing of fingers, and embolic phenomena are important objective signs. The valvular endocardium of the left side of the heart is more frequently affected than any other part of the membrane, and the surface of valve exposed to the direction of the blood stream first becomes affected. Prophylactic treatment is most important, especially directed to the later stages of, and early convalescence from, acute rheumatism. Onset may be latent. On the slightest suspicion of endocardial infection absolute rest and skilled nursing are essential, and salicylates should be continued until improvement is well established, when dosage should be slowly reduced. Further treatment is largely on symptomatic lines, directed against insomnia, for the relief of pain and the correction of digestive and other disorders. Antiserum and vaccine therapy may be tried, but the success of this line of treatment does not seem in any way to approach that which might theoretically be expected, and the results so far obtained by chemotherapy with the mineral germicides are unsatisfactory.

352. Filariasis in China.

MAXWELL (*Philippine Journ. of Science*, September, 1921) considers that filariasis causes a considerable amount of chronic invalidism and economic loss in China. The disease is caused by the *F. bancrofti* through the agency of the mosquito. It does not spread north of the Yangtse Valley, the majority of the cases occurring in a coast belt fifteen to twenty-five miles broad from the Yangtse to the Tonquin border. While the filarial worm may be harboured for years without giving rise to inconvenience, it may cause inflammatory diseases—for example, elephantiasis of the scrotum, lymphangitis, erysipeloid inflammation, dermatitis and cellulitis, abscess, orchitis, arthritis, scrotal gangrene, and haemoptysis; or, by obstructing the lymphatics, give rise to lymphatic varix and fistula, varicose groin glands, lymph scrotum, chyluria, chylous dropsy of the peritonium or of the tunica vaginalis, chylous diarrhoea, and elephantiasis of the scrotum, vulva, legs, arms, mammae, and limited skin areas. Filarial infection apparently does not adversely affect the healing of surgical conditions, and malaria and typhoid, when occurring

in combination with filariasis, are not adversely influenced. The condition is unfavourable to lung disease, especially pneumonia. Although salvarsan treatment has been claimed as destroying the parent worm such destruction is not altogether devoid of risk to the host, and though it is impossible to destroy the mosquito carrier in southern China, the use of a mosquito net, or screening the bedrooms of those infected, is advocated as the most practical preventive measure.

353. Treatment of Epilepsy by Borax and Potassium Tartrate.

TROCELLO (*Ann. di med. nar. e colon.*, November-December, 1921) reviews the recent literature, including the paper by McCartney in the *JOURNAL* of October 9th, 1920, on the treatment of epilepsy by borates, and records his own observations on eight patients with epilepsy of long standing in whom the tartrate of borax and potassium was given in doses of 3 grams daily. In seven cases the attacks were reduced in number and intensity in a more or less considerable degree, complete disappearance of the fits being noted for three months in one case and for one month in another. Lastly, in almost all the cases there was a transformation of the motor attacks into mere spells of vertigo, to which French writers have drawn attention. In five cases the tartrate proved more efficacious than the alkaline bromides. Improvement of the psychical condition was noted in five cases. Trocello's observations therefore confirmed the conclusions of Pierre Marie and his collaborators as to the value of borates in epilepsy. The French writers maintained that the treatment was all the more likely to succeed if the epilepsy was of recent date. The present series, however, shows that good results may be obtained even in cases of long standing. The absence of any depressing action on the mentality or of any disturbance of the gastrointestinal canal, skin, or mucous membranes constitutes an undoubted advantage over alkaline bromides. The new method is therefore specially indicated in anaemia and respiratory catarrh, and various gastro-intestinal and cutaneous diseases, in which bromides are definitely contraindicated. Some of Trocello's cases confirm the observation of previous observers (P. Marie, Gardère, and Rebatton) to the effect that suspension of the treatment causes a reappearance of the attacks in their original frequency and intensity.

354. Fatal Cerebral Lesions after Salvarsan Treatment.

HENNEBERG (*Klinische Wochenschrift*, January 23th, 1922) records three cases of fatal cerebral lesions directly following salvarsan treatment, with detailed accounts of the pathological examination. The patients were in hospital undergoing salvarsan treatment. Briefly stated, the symptoms, in the first case, were those of cerebral irritation and mental confusion, followed rapidly by coma and cyanosis. In the second case irritative cerebral symptoms were followed by coma and right-sided hemiplegia. In the third case coma developed quite suddenly. In the first and second cases the pathological examination revealed haemorrhagic encephalitis. The author uses the term "cerebral purpura" to describe the appearance of the brain sections. In the first case numerous scattered petechial haemorrhages were found in the corpus callosum and in the brain substance around the lateral ventricles. In the second case a small haemorrhage was found in the optic thalamus on each side, and small scattered haemorrhages in the pons. In the third case a large haemorrhage was found in the pons. In the first and second cases the changes were those of haemorrhagic salvarsan encephalitis, similar to the changes in cases previously recorded. In the third case the author considers the large pontine haemorrhage to be of a similar nature, and not an accidental coincidence during the salvarsan treatment; since no disease of the cerebral blood vessels was detected, no indications of previous syphilis could be obtained, and similar haemorrhages have been recorded after salvarsan treatment.

355. The Slightness of the Contagion of Lupus Vulgaris.

RECENTLY a commission on lupus in Germany issued the considered opinion that chronic tuberculous diseases of the skin and adjoining mucous membranes were of little practical importance in the dissemination of tuberculosis. This view is confirmed by experimental investigations made by BURCHARDI (*Deut. med. Woch.*, February 9th, 1922). He inoculated 27 guinea-pigs with crusts and pus from cases of

ulcerating lupus of the skin, but in no case did the guinea-pigs develop tuberculosis. When, however, he inoculated 21 guinea-pigs with bloodstained discharge and scrapings from granulation tissue formed about lupous areas, 90 per cent. of the animals developed tuberculosis. The same differences were observed when material from the nasal mucous membranes of patients suffering from lupus of the interior of the nose was injected into guinea-pigs. Some of the author's earlier experiments were spoilt by the mixed infection to which the guinea-pigs succumbed soon after inoculation. Later he was able to avoid this complication by treating the material to be injected for one to two hours with a 15 per cent. solution of autiformin. This destroyed the bacteria present with the exception of tubercle bacilli.

356. Intercoastal Herpes following Tuberculous Pleurisy.

SCHREIBER (*Bull. Soc. de Péd. de Paris*, January 17th, 1922) reports two cases in children—a girl aged 14 and a boy aged 15—who developed intercoastal herpes in convalescence from tuberculous pleurisy with effusion, the herpes being on the same side as the effusion in one case and on the opposite side in the other. This seemed to indicate that if the tubercle bacillus was responsible for the occurrence of the eruption, as seemed probable, the herpes was not a local complication but a manifestation of a generalized tuberculous infection. Herpes zoster might sometimes be the first sign of tuberculous infection, and therefore appear before the pleurisy.

357. Treatment of Infantile Tetany with Ammonium Chloride.

FREUDENBERG and GYÖRGY (*Klinische Wochenschrift*, February 25th, 1922) conclude from their previous observations that a condition of "alkalosis" exists in manifest tetany, and that this leads to changes in the consistence of the blood as regards active calcium. Since "acidosis" can be produced by ammonium chloride, the authors tried the action of this drug in tetany for short periods (up to ten days). Nine cases of tetany are recorded, in all of which the drug was of service. The results of electrical examination are given, showing the increased galvanic excitability, and especially the increased excitability for the anodal and cathodal opening contractions; this diminished markedly under the action of the drug. The immediate danger from the disease was prevented, and time was gained for other treatment. The action of the drug is symptomatic; it is not suitable as a prophylactic. It is suitable for manifest, but not for latent, tetany. The authors conclude that by the internal administration of ammonium chloride, in doses of 3 to 7 grains daily, to suckling infants liable to tetany spasms, the mechanical and electrical nervous over-excitability can be diminished, and the manifest tetany condition removed. The author also found it of service in a case of post-operative tetany.

SURGERY.

358. X-Ray Examination of Bile Ducts and Biliary Fistula.

TENNEY and PATTERSON (*Journ. Amer. Med. Assoc.*, January 21st, 1922) relate the case of a man on whom a cholecystectomy was performed. The patient made an uneventful recovery from the operation, but a permanent biliary fistula resulted. In order to determine the extent of the fistulous tract and its relations to the duodenum, a duodenal tube was passed and a small amount of milk containing barium was injected into the tube to make its outline clear. At the same time three-fourths of the contents of a one-ounce tube of bismuth paste was injected into the external opening of the fistula; the paste passed in with slight pressure and caused no pain. An x-ray examination was immediately made, and it was found that the liver ducts were extensively injected with bismuth paste. Before the second radiogram was taken (fifteen minutes later) the patient was given buttermilk and barium to drink, so that the stomach might be outlined and assurance made that the duodenal tube was in the duodenum. This was found to be so, and it was further shown that there was no connexion between the fistulous tract and the alimentary canal. The obstruction was apparently at the junction of the hepatic with the common duct. Immediately after the injection of the bismuth paste the patient developed discomfort in the region of the liver; this gradually grew worse, and in twelve hours he began to have extreme distress, morphine being required to relieve the pain. In twenty-four hours he had developed jaundice, but at the end of thirty-six hours the paste gradually began to come out through the external opening, the bile began to flow, and the distress of the patient was much less. The third radiogram, taken at this time, showed that the paste, which had extended to the margin of the liver, was disappearing; and the tube, which

was given the patient to swallow fifteen minutes previously, was looped in the stomach. Two days after the injection of the paste the jaundice was less and the patient had no discomfort; more of the paste came out, and the bile began to flow freely; on the fourth day the liver was almost free from hismith. The patient was apparently no worse for the mechanical obstruction to his liver for a period of forty-eight hours.

359. Gas-containing Abscesses of the Liver.

MASSARI (*Wien. klin. Woch.*, November 24th, 1921) states that only six cases of abscesses of the liver containing gas are on record. In two of these cases (Schenk-Justin, Lenk-Steindl) the lesions were due to gunshot wounds; in one case (Coutcaud and Le Dentu) to communication of the abscess with a bronchus; in two others to affection of the gastro-intestinal tract (Le Dentu); and in one case (Schenk) to the action of bacteria of the enteritis group following meat poisoning. Massari now reports a case of a man, aged 52, who developed a solitary liver abscess following a compound comminuted fracture of the right arm. Amputation of the arm just below the insertion of the deltoid was necessitated by the development of gangrene of the hand and forearm, in which abundant gas formation had taken place, though the condition was not really one of gas gangrene. Sixteen days after the operation the patient developed symptoms of hepatic abscess, and laparotomy was performed, when a large single abscess was found, from which about a litre of pus containing a large quantity of gas was evacuated. Bacteriological examination was negative. Recovery took place.

360. The Operative Treatment of Epilepsy.

THE etiology of epilepsy is obscure and little is known as to its pathology and causes. The recorded cases of cure show that almost anything may seem to cure epilepsy, from severe burns to operations on the intestines. LITTLE (*Boston Med. and Surg. Journ.*, January 19th, 1922) finds that in certain cases of epilepsy operation is beneficial. The difficulty is to pick out the cases that will be benefited, and then to decide what operation should be performed. He makes a report of fourteen cases in which there were no deaths due to operation. In all cases there was some temporary improvement and some were better over a considerable period. His general impression is that the operation was worth while. The type of operation done was generally some form of decompression. In a collection of 81 cases, gathered from the literature of the subject, together with his own 14 cases, it appears that some form of operation (decompression, fenestration or removal of a tumour) has given beneficial results in the majority of cases. If those cases are excluded where extirpation of the cortical centre and of tumour was done, the mortality is not high. Any benefit which may be had from surgical procedure should not be denied, where other measures fail, to this pathetic class of patients.

361. Paralysis of Accommodation due to Arsenobenzol.

MILIAN and PÉRIN (*Paris méd.*, November 12th, 1921) record the case of a syphilitic woman, aged 26, who, during the third series of injections of arsenobenzol, developed a nitritoid crisis at the time of each injection with a large quantity of albumin in the urine and paralysis of accommodation. The albuminuria was explained by vaso-dilatation of the renal glomeruli. Examination of the eye showed slight oedema of the conjunctivae, normal fundi; and myopia due to spasm of accommodation. The writers attribute the condition to involvement of the sympathetic, and suggest that all patients undergoing treatment with arsenobenzol should be systematically examined by an ophthalmologist.

362. The Efficiency of Various Haemostatics.

ELYING (*Finska Läkaresällskapets Handlingar*, November and December, 1921) has investigated by Bürker's method the influence of various haemostatics on the blood. Exposures of the spleen to the x rays had a marked effect in all but one of twelve cases, the average increase in the rate of coagulation being between 25 and 40 per cent. In one case the rate of coagulation was increased by as much as 67 per cent. X-ray exposures of the liver and heart had a similar but less marked effect, and this was probably due, in part at any rate, to the action of the x rays on the blood circulating through the organs exposed. Though the x rays were thus shown to have a definitely haemostatic action, the author is doubtful as to their practical value at the present stage. He has also tested the haemostatic properties of sodium chloride and of the diuretic ephyllin, both of which were administered by intravenous injection. Both increased the rate of coagulation considerably, but it was necessary to give large doses of the sodium chloride if this effect was to be obtained, and ephyllin betrayed the serious fault of exciting marked

tachycardia. By far the best haemostatic was found, to be calcium chloride; in one case the intravenous injection of 10 c.cm. of a 10 per cent. solution increased the rate of coagulation by 91 per cent. The author recommends the intravenous injection of 20 c.cm. of a 15 per cent. solution (3 grams CaCl_2), both as a prophylactic an hour or two before a severe operation, and also in the treatment of haemoptysis and other haemorrhages.

363. Hydatid Cyst of the Kidney.

ESTOR (*Bull. et Mém. de la Soc. de Chir. de Paris*, February 7th, 1922) records a case of a large hydatid cyst of the left kidney, and points out that hydatids are uncommon in this situation and cause much difficulty in diagnosis. His case occurred in an agricultural worker aged 42 years. The patient had noticed a swelling in his left flank for two years, but as it caused no trouble no treatment was thought necessary. Subsequently the swelling was diagnosed as an enlarged spleen, but a blood examination proved negative. The tumour then occupied almost the whole of the left side of the abdomen and extended from the iliac crest to the costal margin. As the patient even then gave no evidence of a lesion of the urinary tract and the urine examination proved negative, a diagnosis of hydatid cyst of the spleen was made. Abdominal exploration showed the true origin of the cyst. Puncture of the cyst yielded two and a half litres of fluid, and an injection of 1 per cent. formalin was made into the cyst to sterilize it. The sac was then opened and the hydatid membrane completely removed. To lessen the size of the cavity he removed all the fibrous capsule and was only stopped when kidney tissue presented. The excision removed about a third of the sac; the remainder was completely sutured up without drainage. Two tubes were placed outside the sac and removed a few days later. The patient made a complete recovery.

OBSTETRICS AND GYNAECOLOGY.

361. The X-ray Treatment of Sarcoma of the Uterus.

SEITZ and WITZ of Erlangen (*Deut. med. Woch.*, March 17th, 1922) review their experiences during the past four to five years with the x-ray treatment of primary sarcoma of the uterus and of myoma of the uterus which has undergone secondary sarcomatous degeneration. Of four patients treated almost five years ago, one was a hopeless case from the outset, and death occurred a few weeks after treatment. Another survived treatment by three and a half years before dying of metastases in the region of the stomach. The remaining two are still alive and well, nearly five years after treatment. The authors refer to three other cases observed for five years and seven observed for two years after treatment, and all are still alive and well. Of 15 cases of sarcomatous degeneration of myomata of the uterus observed for two to four years after x-ray treatment, 13 are still alive. Altogether the authors have treated 35 cases, and 26, or 74 per cent., are still alive and well two to five years after treatment. They believe that a permanent cure—that is, freedom from relapse for five years—can be achieved in 50 per cent. by x-ray treatment, whereas the best results of operative treatment show recovery in only 20 per cent. after an observation period of three and five years (Veit). Discussing the diagnosis of sarcoma of the uterus, the authors admit that even by exploratory excisions and microscopic examinations it is not always possible to distinguish between malignant and non-malignant disease, but they have found the reaction of tumours of the uterus to the x-rays of great diagnostic value, the sarcomatous tumour dwindling rapidly in two or three weeks after a full sarcoma dose (60 to 70 per cent. of the erythema dose), while the benign myoma may take a year and a half to disappear after a "castration exposure" (34 per cent. of the erythema dose). In the latter case this effect is achieved by eliminating the activities of the ovaries, whereas in the case of sarcoma the rapid dwindling of the tumour is due to the direct action of the x-rays on it.

365. X-ray Examination of the Pelvic Colon in Gynaecological Diagnosis.

FROM a study of 52 cases of pelvic tumour, ODESCALCHI (*Annali di Ostetricia e Ginecologia*, February 28th, 1922) concludes that x-ray examination of the ileo-pelvic colon, injected with a bismuth emulsion in gelatin, constitutes a valuable method in the diagnosis of large pelvic tumours, and has the advantage of being less inconvenient and less dangerous to the patient than the insufflation of gaseous mixtures into the pelvic peritoneum, as in Rubin's and other methods. When the pelvic tumour is the size of the three-months pregnant uterus, or larger, the mobile iliac and pelvic colon undergoes displacements, the radiological diagnosis of which, especially when combined with bimanual examination, may

afford valuable information as to the origin and nature of the tumour. In the case of tumours of the right adnexa, for example, the ileo-pelvic colon is displaced to the left, and forms an inverted U-shaped loop (with concavity directed downwards) parallel and internal to the descending colon. When the growth is on the left side four-fifths of the pelvic colon is seen on the screen as an arc of a circle, encircling the tumour from the sacral concavity to the left iliac fossa. As a result of examination by this method the writer was frequently able to amplify or correct the original clinical diagnosis.

366. Varicocele of the Broad Ligament.

FROM a study of the literature and of twenty personal cases ENGELMANN (*Zentralbl. f. Gynäk.*, March 4th, 1922) concludes that varicocele of the broad ligament is not of very infrequent occurrence and has a somewhat characteristic symptomatology. Those affected are usually in the third or fourth decade and are almost invariably multiparæ; the symptoms usually date from a pregnancy, and consist in pains in the abdomen and back, which are relieved by lying down, well marked in the standing position, and most severe in connection with defaecation or with sexual excitement. More than half of the writer's patients, all of whom came to operation, suffered coincidentally from uterine retroversion or prolapse; seven showed morbid conditions of the adnexa, and in four only did the broad ligament varicocele constitute the sole pathological condition discernible. The diagnosis can rarely be made before operation. Treatment is largely that of the complications which are present, but even in uncomplicated cases the author is averse to simple extirpation of the venous plexus, and regards removal of the adnexa of both sides and of the fundus uteri (one ovary being conserved if possible in young women) as the method of choice.

367. Perforation of Uterus without Destruction of Ovary.

BENTIN (*Deut. med. Woch.*, March 17th, 1922) records as a curiosity the case of a woman, aged 30, who attempted to induce abortion by injecting a solution of soap into the uterus with an aluminium syringe. Labour-like pains followed and she developed fever and rigors. A doctor, summoned seven days later, attempted to evacuate the uterus, but the stricture he withdrew from it was not the placenta but a coil of intestine. So he sent her to hospital, where she was at once operated on. Probably owing to the tilting of the pelvis the intestine was found to have slipped back into the peritoneal cavity from the opening, admitting one finger, in the lateral wall of the uterus. The intestine proved to be intact, and after supravaginal amputation of the uterus and adequate provision for drainage the operation was completed. The patient was afebrile by the seventh day after the operation. The uterus contained a practically intact ovum; only at its lower pole was it partially detached from the neighbouring structures and covered by a clot of blood.

368. Ectopic Gestation.

NAVARRO (*Rev. Española de Obstet. y Ginecol.*, 1921, 61) records a case in which a patient after three months' amenorrhoea suffered from symptoms of internal haemorrhage, pyrexia, and faecal and urinary obstruction. Examination showed the presence of a retroterine haematocoele following tubal abortion; the acute symptoms subsided gradually, and on the fifth day the placenta was passed per rectum. Eight days later the general condition became worse, and after very considerable pain the foetus was passed by the same route. Recovery took place ultimately. The passage of such an early foetus per rectum is unusual; the majority of recorded cases have concerned foetuses of at least five months and have been subjected to operative intervention.

369. Five Children at a Birth.

COSENTINO (*R Morgagni*, February 5th, 1922) reports a case of five living children at one birth—two female and three male. The diagnosis of multiple pregnancy is difficult. Auscultation of the foetal heart may indicate the presence of twins. In multiple births the male sex as a rule preponderates, and often the father is older than the mother. The author believes that three out of the five children developed from one follicle enclosing many ova. Veit, out of 298,928 twin births, found 153,723 males and 145,205 females. Pregnancy in these cases of multiple births is often shortened owing to the want of room in the uterus. The first three were born with vertex presentations, the fourth a breech, and the fifth a trunk presentation. There was an interval of only ten minutes between the births of the first two, the third was extracted by forceps, and the fourth and fifth (after turning) by the hand. The rarity of five at a birth is shown by some statistics of Wappaus, who only records 1 in 17,730,674 births: Three placentas were expelled.

370. The Dangers of the Intrauterine Pessary.

WETTERWALD (*Schweiz. med. Woch.*, March 16th, 1922) notes that the wearing of an intrauterine pessary as a contraceptive has become deplorably common—nurses, midwives, and quacks, as well as certain doctors, recommending it for this purpose. In addition to recording in detail a case of fatal septic abortion following the use of an intrauterine pessary, the author draws on the literature of the subject to show that pregnancy often occurs in spite of this device. One writer alone (Gummert) has collected as many as 93 cases of pregnancy in association with the wearing of an intrauterine pessary, and out of 72 cases of abortion by women who had worn this pessary as many as 61 proved febrile. In the author's case the pessary had been worn for a year and a half, and all had gone well while the patient had removed the pessary every month at the onset of menstruation. Neglect of this precaution was shortly followed by the abortion which terminated fatally. It is probable that, while the intrauterine pessary is at all times a dangerous foreign body calculated to promote septic infection of the uterus, its presence there during menstruation considerably enhances the risks of injury followed by infection.

PATHOLOGY.**371. Metabolism of Bacteria.**

KENDALL and a number of his co-workers publish (*Journ. of Infect. Dis.*, February, 1922) a record of their researches into the nitrogenous metabolism of the coli-typhoid group of bacteria. They show that bacteria require nitrogen for structural needs and carbon for energy requirements, and that in a medium containing both carbohydrates and proteins the former are used first, and only when the carbohydrates are exhausted are the proteins attacked. This is embodied in the dictum, "Carbohydrate spares protein from utilization for energy." Bacteria were grown in various media, and the nitrogenous constituents examined at stated periods of time and the ratio of the nitrogen fractions compared. In the case of *B. dysenteriae* (Shiga) they showed that this organism attacks most readily the so-called carbohydrate portion of the protein radiol, and builds up its protein from the polypeptides present in the original culture. With the typhoid and paratyphoid groups of bacilli also they found that the polypeptides were the ingredients most readily made use of in sugar-free media, but when glucose was present this portion was spared. Their observations on the Schmitz bacillus lead them to distinguish it definitely from Shiga's bacillus, which it closely resembles, for the Schmitz bacillus does not select the carbohydrate portion of the protein molecule for its primary attack, and it is capable of producing more pronounced proteolysis, indicated by the formation of indol. The organism known as *B. alkalescens*, on the other hand, although at one time confused with *B. typhosus*, is by these authors relegated to a position in company with non-pathogenic coliform bacilli. The proteolytic enzyme secreted by *B. proteus* is used for the preparation of protein for assimilation, and has no demonstrable rôle in the intracellular utilization of the protein by the bacteria.

372. Vitamins and Immunity.

BIONDO (*Il Policlinico, Sez. Prat.*, January 2nd, 1922) carried out experiments on pigeons to determine the effect of deprivation of the vitamins A, B, C, either separately or in combination, on (1) the natural immunity of the birds to the anthrax bacillus, (2) the weight of the body, (3) the leucocyte picture, (4) the opsonic index of the blood for the anthrax bacillus. His results were as follows: (1) An exclusive diet of autoclaved rice (absence of vitamins A, B, C), or of autoclaved rice and onion (absence of vitamins A and B), or of autoclaved rice and butter (absence of vitamins B and C), or of autoclaved rice, butter, and onion (absence of vitamin B), caused the death of the pigeons in a time varying from fifteen to twenty-four days from the commencement of the diet, with symptoms of avian polyneuritis. Under this diet, in which there was a constant absence of vitamin B, there was (a) loss of natural immunity to anthrax; (b) diminution in the original weight of the pigeons by about 20 to 40 per cent.; (c) leucopenia with considerable increase of pseudo-eosinophils, extreme reduction of lymphocytes, and appearance of transition forms, leucoblasts, and young red cells; (d) considerable and progressive diminution of the opsonic index of the blood for the anthrax bacillus. (2) An exclusive diet of dry peas (absence of vitamins A and C), or of dry peas and onions (absence of vitamin A), or of dry peas and butter (absence of vitamin C), did not cause any characteristic morbid symptoms in pigeons which had been kept on this diet for eighty days, except a slight arrest of development

and almost complete abolition of spontaneous movement, especially of flight. With such diets, in which vitamin B was always present, the pigeons did not lose their natural immunity to anthrax, even if inoculated eighty days after commencement of the diet, their weight slightly increased, their leucocytes did not undergo any remarkable changes, and the 'opsonic index' of the blood for the anthrax bacillus remained the same as before. Biondo concludes that vitamin B is sufficient in alimentation to the exclusion of the others.

373. Studies on the Pneumonic Exudate.

A CONTRIBUTION by NYE (*Journ. Exper. Med.*, February, 1922) to the study of the factors operating in the process of resolution of the pneumonic lung serves to confirm the previous well-known work of Opie and of other American observers. The subject was attacked by making a comparison of the proteolytic activities of portions of normal and of consolidated lung tissue obtained from a case of Type I pneumonia, the substrate used being fresh horse fibrin. Total nitrogen determinations by Folin's macro-Kjeldahl method and amino-nitrogen determinations by Van Slyke's method were made on digestive mixtures of different degrees of acidity. As a result it was found that washed cellular suspensions of pneumonic lungs contain a protease, derived chiefly from the leucocytes of the exudate. This protease is able to exert its most marked effect on fibrin at a hydrogen-ion concentration of pH 8.0—that is, in a slightly alkaline medium. On the other hand, washed cellular suspensions of normal lungs were found to contain a protease which is most active in a moderately acid medium—pH 4.0. The two enzymes are apparently distinct. That occurring in normal lung is derived from the endothelial cells, that in the pneumonic lung from polymorphonuclear leucocytes. Moreover, the latter is considerably more powerful than the former. It appears evident that the cause of the clearing up of the pneumonic exudate is due to this tryptic ferment, which digests the network of fibrin in the alveoli, thus liquefying the highly viscous proteins and enabling the resultant split products to be coughed up or removed in other ways.

374. Vaso-constrictor Substances in the Blood in High Blood Pressure.

HÜLSE (*Zentralbl. f. inn. Med.*, January 7th, 1922) examined various cases of high blood pressure, consisting of four of acute glomerular nephritis, two of chronic nephritis, and three of essential hypertension, for substances possessing a vaso-constrictor action, such as adrenaline. The results were negative in each case. The question therefore whether hyperadrenalinæmia is the cause of a marked rise of blood pressure could be definitely answered in the negative. Even in the highest readings, such as 250 mm. Hg, no adrenaline could be found in the arterial blood. It can therefore be concluded with certainty that the rise in the blood sugar found by some observers in cases of high blood pressure had nothing to do with increase of adrenaline in the blood. Hülse himself never found any increase of blood sugar in acute diffuse nephritis, but often, on the contrary, a remarkably small quantity. The occasional increase of blood sugar in chronic nephritis is best explained, as Fahr suggests, by a sclerosis of the pancreatic vessels. Hülse also concludes from his experiments that there are no other vaso-constrictor substances apart from adrenaline in the blood of patients with high blood pressure, and that therefore there are other causes for the general vascular spasm which leads to hypertension. He considers it probable that the rise of blood pressure in the various forms of hypertension is due to different causes, and suggests that in acute nephritis deficiency in calcium is the cause of the rise of blood pressure.

375. Uterine Tissue in the Ovary.

JANNEY (*Amef. Journ. of Obstet. and Gynec.*, February, 1922) records three cases in which he has discovered by microscopic examination the presence of uterine among ovarian tissue. The first patient came to operation for chronic inflammatory adnexal disease; both ovaries contained endometrial tissue in connexion with the wall of a small cyst. A second patient suffered from prolapse and lacerated cervix; uterine tissue occurred on the surface of one ovary. The third patient had a large bleeding uterus and a cervical polypus; the glandular tissue was contained in the wall of a small cyst of one ovary. The patients' ages were respectively 41, 48, and 44. In each case the uterine tissue was composed of stroma and epithelial elements in about the same proportion as in normal uterine mucosa; the nuclei were of typical and regular size and shape, and mitotic figures occurred rarely. Gland tissue was present both in typical arrangement and also as irregular diverticula. These findings can be explained as due to teratoma, metastasis, or anomaly: the writer believes the third explanation to be correct.

A British Medical Association Lecture ON RADIUM THERAPY.

BY
ROBERT KNOX, M.D.

HONORARY RADIOLOGIST, KING'S COLLEGE HOSPITAL; DIRECTOR,
RADIO-THERAPEUTIC DEPARTMENT, CANCER HOSPITAL.

THE subject on which I have been asked to speak covers so much ground that it will be possible only to deal with broad principles and give an indication of the value of radium in treatment—more particularly in the treatment of malignant disease, for it is in this field that so much has been expected from the use of radium.

New agents, whose powers are not at first properly appreciated, must pass through the stages of overestimation, depreciation, and possibly rejection, before their true value is arrived at. When an agent which appears to act upon all structures with which it comes in contact is employed, the difficulties increase proportionately with its effect upon these structures; and the greatest care must be exercised in all attempts to estimate its value. The radio-active bodies belong to this class, and it is very difficult even approximately to estimate their value.

The range of therapeutic activity of radiations is an exceedingly wide one, extending from the ultra-violet to the penetrating gamma rays of radium. The fundamental principle of radiation therapeutics is easily understood; it is realized that the wave length of the radiation is the determining factor. When the correct wave length for a particular depth has been estimated, it is then merely a matter of time—that is, duration of the exposure—to produce a particular effect upon the tissues. The effect of radiations is dependent upon the power of absorption the tissues possess for these particular wave lengths, and the absorption of the radiations causes changes in the cells, which may vary in their degree; amongst other's chemical changes may result which have a far-reaching effect upon the organism.

In order to obtain effects over a wide range of morbid processes, it is necessary to have at our disposal radiations of all wave lengths, so that any condition may be treated. In x rays and radium we possess the particular values required. Large quantities of radium may be used with advantage, as, for example, at the Middlesex Hospital, where $5\frac{1}{2}$ grams have been used for varying times in the treatment of malignant disease.

Relative Values of X Rays and Radium.

A great deal of unnecessary discussion has taken place on the relative values of x rays and radium rays, the assumption being that these agents act differently on the tissues. The matter will be more clearly understood if we assume that we are dealing with radiations which have a very wide range of wave length, the gamma ray from radium representing the extreme limit of penetrating power. Given an equal wave length from either agent the effect will be the same. The x -ray value has been, up to the present, limited by the inability of the apparatus to generate the high voltage necessary to produce x rays equal to the gamma ray from radium. So far it has only been possible to use voltages from 200,000 to 300,000; the voltage required to produce x rays equal to the hardest gamma rays is approximately between one and two millions. Nevertheless, the voltages of 250,000 give us a very useful radiation, which, if applied in sufficient intensity, may give very good therapeutic results. For example, cancer of the cervix uteri may be influenced by massive doses of x rays administered through several ports of entry. The dose may have to be very prolonged, from five to eight hours at a single treatment. Good effects are claimed for this particular technique. Radium is more applicable to the growth, and gives very brilliant results; these are, however, purely local, and are not permanent. The use of both agents would appear to be a rational procedure. By this method of attack it is possible to obtain the maximum effect from both agents, the radium acting from a local focus, and spreading outwards to the periphery, while the x rays are used from the periphery to a central focus point. The tissues are thoroughly saturated and simultaneously attacked from all points. It is possible that in this way peripheral extension of the new growths may be checked.

Superficial lesions are the most favourable for treatment, in so far as they can be kept under continual observation and

progress noted; occasionally it is possible to remove a piece of tissue for examination, when changes in tissue due to the treatment may be noted, and the exact character of the condition ascertained. The study of the changes induced in superficial structures gives an accurate indication of the type of case likely to respond to treatment, and also illustrates clearly the probability of influencing deeper morbid conditions; for it will be seen that the simple conditions, such as chronic inflammatory lesions, simple ulcers, naevi, etc., can be beneficially treated with a remarkable accuracy, while those conditions which verge on the malignant—that is, rodent ulcer and epithelioma—are more intractable, the very malignant forms of carcinoma frequently resisting treatment altogether.

Exactly the same sequence is noted in the so called deep therapy. The effects are, however, much more difficult to obtain on account of the greater difficulty in administering the correct dosage; more penetrating radiations are required in order to reach the depth of the lesion, while the intervening tissues absorb in a diminishing ratio, according to their depth from the surface, the radiations which have to pass through them to reach the tumour. When these difficulties are allowed for it will be seen that the order of response is almost identical with that of the more superficial lesions.

Consideration of the Physical Data of Radium.

Before dealing with the technique and practical application of radium a short reference to the physics of radium will be useful.

The physics of radium is a most interesting but somewhat difficult subject for the average medical man, who has long ago left behind him what elementary knowledge he possessed, as a student, of physics. For future medical men there can be no doubt that the physics side of the curriculum must be increased, and it would be well if all practitioners kept closely in touch with this subject throughout their years of practice. A correct appreciation of physical laws will enable them to understand many things which are at present obscure.

It is now known that the x rays are another manifestation of radiant energy, of which light and heat are familiar examples. The x rays resemble light rays in almost every particular, the chief difference being that the x rays have wave lengths about 5,000 times shorter—that is, the x rays are situated far beyond the violet end of the visible spectrum, and may be regarded in a sense as a "treble" form of ultra-violet light. It was this very minuteness of wave length—a distance of the same order as the size of atoms—that defeated all the earliest attempts to direct and sort out the rays. Just about a single octave of light waves is visible to the eye.

RADIUM.

The prominent member of the uranium series of radio-active elements, belonging to the alkaline earth group of elements. Its parent is ionium, and its disintegration product radium emanation. Radium was discovered in 1898 by M. and Mme. Curie. The discovery was preceded by Becquerel's discovery of radio-activity in 1896.

RADIUM SALTS.

The word radium, as it is generally used, signifies a radium salt, and in a stricter sense generally up to the present radium bromide ($\text{RaBr}_2 \cdot 2\text{H}_2\text{O}$). Other salts are used, however, so in describing preparations of radium it has become customary, as well as more accurate, to state the radium element content of the salt. Buyers of radium are advised in their own interests to have the salt certified by the National Physical Laboratory, Teddington.

The salts most commonly used are the sulphate, bromide, and chloride. The hydrated bromide ($\text{RaBr}_2 \cdot 2\text{H}_2\text{O}$), when pure, contains about 53.6 per cent. of radium element. The pure anhydrous radium bromide (RaBr) contains 58.6 per cent. radium element. The pure sulphate (RaSO_4) contains 70.2 per cent. radium element and pure radium chloride (RaCl_2) contains 76.1 per cent. radium element. The chloride and bromide are soluble in water, while the sulphate is insoluble in water and soluble in acids.

Radium emanation has a steady decay period; it falls to half value in about five days; when using the emanation in treatment the decay value has to be taken into account in estimating the exposure.

In whatever manner the radium is used—that is, in tubes, plaques, or in the form of emanation in suitable containers—

TABLE I.—Uranium-Radium Family.

(1) Name.	(2) Atomic Weight.	(3) Half Decay Period.	(4) Radiation.
Uranium 1	238	5 billion yrs.	Alpha.
Uranium X1	234	24.6 minutes	Beta, gamma.
Uranium X2	234	1.15 minutes	Beta, gamma.
Uranium 2	234	Abt. 1,000,000 yrs.	Alpha.
Ionium	230	Abt. 100,000 yrs.	Alpha.
Radium	226	1,700 yrs.	Alpha.
Radium emanation (niton)	222	3.85 days	Alpha.
Radium A	218	3 minutes	Alpha.
Radium B	214	26.8 minutes	Beta, gamma.
Radium C	214	19.5 minutes	Beta, gamma (alpha).
Radium C2	210	1.4 minutes	Beta, gamma.
(side reaction 0.03%) End 0.03%	210	—	—
Radium C1	214	0.00001 second	Alpha.
(main reaction 99.97%) Radium D	210	16.5 yrs.	Soft beta.
Radium E	210	5 days	Soft beta.
Radium F (polonium)	210	136 days	Alpha.
Radium G (end product)	206	—	No rays, atoms stable.

it is found that there are three types of rays given off: alpha, beta, and gamma. The alpha ray is not used to any extent. The beta and gamma rays are most active, and induce changes in the tissues which are most important from the therapeutic point of view. It is on a correct appreciation of the biological action that successful treatment will depend. The point cannot be dealt with fully now, but it is essential that the radiologist be fully conversant with this matter.

Beta rays are negative electrons shot out from the nucleus of the transmitting radium atom with a velocity which in some cases is nearly that of light. Beta rays are more penetrating than alpha rays, the swifter or harder beta rays being half absorbed in almost 1 mm. of soft tissue or 0.1 mm. of lead or silver. The next equal thickness of these materials will then absorb about 50 per cent. of the remaining ray, so that 10 mm. of tissue, or 1 mm. of lead or silver, absorbs 99.9 per cent. of these hard beta rays. The beta rays from radium B and C, in equilibrium with a gram of radium element, produce per hour 4.3 calories of heat. A bundle of parallel beta rays will be deflected from its path by passing through a strong electromagnetic or electrostatic field due to their negative charge, and observations of this deflection in fields of known strength serve to measure the velocity of the beta rays, since the faster the electron travels the less the deviation in a field of given strength. The beta rays are closely related to the gamma rays.

Gamma rays are ether vibrations of very short wave lengths (therefore similar to light and x rays); they are caused by the rapid vibrations set up in electrons in the structure of the transmitting element by the electrostatic repulsion between the electron and the escaping high-speed beta ray. The hardest gamma rays from radium B and C are due to beta rays which have initial velocities corresponding to differences in potential of from 500,000 to 2,000,000 volts, and it is probable that the production of x rays of the same short wave length as the gamma rays from radium will require the use of such high potentials.

Recent work, using the molecular crystal structure as a space grating, has led to the determination of the wave lengths of the characteristic x rays and of the softer gamma rays. The wave length of the hard gamma rays is too small to be satisfactorily examined by this method. It is estimated that the wave length of the hard gamma rays lies between 0.01 and 0.001 Angström unit, while the x rays lie in a range between 10 and 0.05 Angström unit, visible light 7,200 to 4,000 Angström units, ultra-violet in the range 4,000 to 200 Angström units, and the longer radiant heat waves beyond the red run from 0.06 mm. down to 7,600 Angström units, the Hertzian or wireless waves following on these.

Secondary rays are formed when these primary rays impinge upon matter. The alpha rays give rise to a delta ray. Secondary beta rays are produced in matter by the absorption of the gamma rays.

Filtrations of Radiations from Radium.

For this purpose metal filters are commonly used. These are silver, brass, steel, lead, gold, platinum, and aluminium; the thickness in millimetres of these substances necessary to absorb 99.9 per cent. of the hard beta rays from radium is as indicated by the figures following:

Silver	1.0 mm.	Gold	0.6 mm.
Brass	1.3 "	Platinum	0.5 "
Steel	1.4 "	Aluminium	4.0 "
Lead	1.0 "		

The most useful screens are those of silver and brass.

TABLE II.—Density and Screening Power of Various Materials.

Ray Absorbing Material.	Approximate Density.	Thickness of Absorbing Material required to absorb 50 per cent. of the Hard Beta Rays of Radium.	Thickness re- quired to absorb 99.9 per cent. of Hard Beta Rays of Radium.
Water	1.0	1.00 mm.	10.00 mm.
Gum rubber	1.0	1.00 mm.	10.00 mm.
Soft tissues	1.0	1.00 mm.	10.00 mm.
Bone	1.7-2.0	0.60 mm.	6.00 mm.
Glass	2.6	0.40 mm.	4.00 mm.
Aluminium	2.7	0.40 mm.	4.00 mm.
Steel	7.7	0.14 mm.	1.40 mm.
Brass	8.5	0.13 mm.	1.30 mm.
Nickel	8.7	0.13 mm.	1.30 mm.
Copper	8.9	0.13 mm.	1.30 mm.
Silver	10.6	0.10 mm.	1.00 mm.
Lead	11.3	0.10 mm.	1.00 mm.
Gold	19.3	0.05 mm.	0.50 mm.
Platinum	21.5	0.05 mm.	0.50 mm.

Secondary radiations are given off from metal filters, and these in their turn may have to be filtered because of their injurious action upon the skin; good secondary filters are paper, rubber, gauze, etc.

Action of Radiations upon the Tissues.

The physiological effects of the radiations from the radioactive substances are attributable to the "photo-electric" effect—that is, the liberation in the structure of the tissue cells of negative electrons. In the case of primary beta rays which are negative electrons their absorption in tissues suffices to start the action. Gamma rays, by their action in evicting secondary beta rays, produce a similar action by the absorption of these secondary beta rays.

When the aim of the exposure is to utilize the beta rays from radium compounds the duration is so relatively short that the gamma ray effect is negligible; but when it is desired to obtain the effect from the more penetrating gamma rays filtration is necessary to cut off the beta rays because of their greater action upon the superficial structure. When dealing with the effects of radiation upon the deeper structures it is necessary to remember that from a point source the intensity of the radiations diminishes inversely as the square of the distance from the source of the radiations. Consequently from a small radium tube, if the intensity of the radiations at 1 mm. is set at unity, at 2 mm. the intensity is 0.25, at 3 mm. 0.11, at 4 mm. 0.06, at 10 mm. 0.01, at 2 cm. 0.0025, at 3 cm. 0.0011.

It is evident from a consideration of these figures that the physiological effect of the gamma rays is limited to distances of 2 to 3 cm. in the treatment of malignant growths, while the dose required to induce the disappearance of the new growth is one which will almost produce a similar effect upon adjacent normal tissue. It also furnishes a scientific proof of the need for thoroughness in the technique of the treatment of malignant disease.

In whichever way the radiations produce these effects—and this is a debatable point on which sound arguments can be advanced on either side—it is imperative that if the tumour is to have administered to it an equal dose of radiations throughout its mass, the radium must be distributed at equal distances, and each tube must have an equal activity.

RANGE OF ELECTROMAGNETIC WAVES

UNIFORM VELOCITY 300,000 KM PER SECOND

[1 ÅNGSTRÖM UNIT = 10^{-8} CENTIMETRE]

VISIBLE SPECTRUM

Illustrating diagrammatically the wide range of electromagnetic waves in Nature. (By kind permission of Dr. G. W. C. Kaye.)

For this reason it is suggested that the most rational technique is to employ that in which the radium is placed in needles or small tubes of an equal capacity and having filters of equal size. The tubes must be placed at distances not less than 2 cm. apart, and all portions of the tumour should be exposed equally. To obtain this, in many cases of malignant disease a most complete surgical operation will be required, and it is essential that a large quantity of radium should be available. The quantity of radium in each tube need not be very large: 10 mg. of element furnishes a fairly active source of radiation; in other cases 25 mg. may be used in each tube.

An alternative to the radium in such cases would be to use the penetrating α rays. Combined treatment ensures very thorough radiation of the tumour and its lymphatic field.

The constant endeavour of the α -ray instrument designer has been to increase the power of the α -ray machine and the vacuum tube in order that radiations of shorter and shorter wave lengths, and therefore greater and greater penetration, could be produced. It is now within the range of practical therapeutics to apply wave lengths of radiation, the production of which necessitates the use of voltages up to 300,000. Great claims are made for the efficiency of the radiations when employed in sufficient intensity and long exposures in the treatment of malignant diseases. It will be increasingly difficult, for technical reasons, to exceed that voltage to any appreciable extent. It is therefore a question whether we should not be content with the use of α -ray apparatus working up to 300,000 volts, and rely upon radium for wave lengths beyond those produced at that voltage.

The most important point would be, then, to ensure that a sufficient quantity of radium might be available. For hospital work a well-equipped department would require to have at least 500 milligrams in tubes, and possibly a maximum of 2 grams would be required. Apart from the difficulty of having sufficient radium in the institution, the other argument for centralization of all radiotherapeutic work, especially in deep therapy, is the fact that anaesthetics and surgical operations are often required. Blood examination should be made at intervals, and patients undergoing such heavy treatment must be placed in a hospital or a private nursing institution. The success of radiation therapy depends very largely upon the work of a number of experts acting in unison. Such combined work can more readily be carried out in a large institution.

The next point to discuss will be the varieties of disease likely to benefit from radium treatment. These may be briefly divided into two groups—non-malignant and malignant.

Radium Applications in Non-Malignant Cases.

It is not necessary to discuss cosmetic conditions other than to sound a note of warning in the treatment of the so-called port-wine stains. The greatest care must be taken in these conditions, otherwise the patient will present a result fully as disfiguring as the original mark.

In angiomas of all sizes radium is doing work that is simply remarkable, entirely removing this condition from the surgical field. This is particularly so when dealing with children.

In uterine fibroids, in 40 per cent. of the cases radium or α rays should be the agent of choice, but strict regard must be given to certain contraindications.

In uterine hemorrhage radium is almost a specific, but here

again due regard must be given to the prevention of certain annoying immediate after-effects, and care must be exercised to ascertain the cause of the haemorrhage. It is well to make it a rule only to treat these cases after consultation with a gynaecologist.

In subacute and chronic leucorrhoea, according to recent reports, radium has proved to be efficient when other methods have failed.

In papilloma of the bladder radium is used after fulguration or operative measures.

In cases of inoperable hypertrophic goitre radium is being employed more and more; in exophthalmic goitre the tendency seems to be in favour of radium as the agent of choice.

The leukaemias offer a large palliative field, and radium seems to control the condition longer than other single methods now employed. Raying the spleen, with transfusion in severe cases, is believed to be the method of choice in many of these conditions.

Enlarged thymus in children, according to a recent article by Hienblein, is a field in which radium comes to the front as the agent of choice.

Recent reports seem to indicate that radium might occupy as prominent a place in the treatment of cataract as it now does in the treatment of spring catarrh.

A surgeon seeing the results produced with radium and α rays in tuberculous adenitis will be induced to combine radiation treatment with the surgical if in a number of cases he does not recommend its adoption in the first place.

Radium Applications in Malignant Diseases.

At the present time, however, he

Cancer of the lip, when springing from the skin surface, is occasionally treated by radium. Springing from the mucous membrane, (and very early) it is treated with surgery and radium, with α rays over the glands of the neck and chest. In advanced cases radium and α rays are used over the lesion and glands, including the glands of the chest.

Cancer of the lingual and buccal mucous membrane is treated with radium and fulguration. No sharp-cutting instrument should be used in this region. Salvarsan may be administered as a routine agent in these cases, giving the salvarsan at the height of the radium reaction. This is useful because it is possible to get secondary effects from the combination.

Treatment of malignant disease of the antrum should be operative plus radium. Metastasis does not occur so early in these cases, but the glands should be rayed as a routine measure.

Cancer of the oesophagus is a radium case—with perhaps surgery—if it is the very early stage. Radium is the best palliative agent in advanced cases, but must be used with care, because of the effect of the rays on the adjoining tissues. Very penetrating α rays may be used from the skin surface.

Cancer of the stomach and intestinal tract is treated surgically, followed, if possible, by radiation. The mechanical difficulties in placing radium in the stomach have not been overcome.

Early cancer of the breast is considered surgical, and radium has rendered seemingly inoperable cases operable. Only in inoperable advanced cases is radium alone employed, and then for its palliative effect. Post-operative radiation treatment is recommended in all cases of cancer. The best time for prophylactic treatment is a question that must be decided for the individual case.

Cancer of the rectum is a condition not treated satisfactorily from any standpoint. If it is inoperable, it should be treated by radium and α rays. Colotomy should be performed to prevent irritation to the parts. Radiations should be applied from all available aspects.

Cancer of the prostate should be removed (if early) and radium tubes and oedles buried at the time of operation. If inoperable, it may be treated by the use of radium oedles via the perineum, or the cross-fire method via rectum and urethra.

In cancer of the bladder radium will be useful, and a suprapubic operation is done in order to facilitate the placing of the radium and to provide for good drainage.

Early cancer of the fundus uteri is a surgical condition if the patient is in a condition to stand a radical operation; otherwise it is a case for radium, and no case, however severe, should be denied the palliative action of radium.

Much of the work which has been done in the past has been experimental and empirical. The technique has been extremely crude, and often left in the hands of men who from their lack of skill and training have not been able to use the radium to the best advantage. But haphazard methods have no place in present-day technique. Take, for example, cancer of the cervix uteri. The patient must be thoroughly prepared as for operation. The gynaecologist is the man best fitted to deal with these very difficult cases. Small quantities of radium or emanations from radium in metal tubes are used. The needle already described is most suitable for this class of work. A tube may be introduced into the cervical canal; around this small needles are inserted into the growth in positions where the greatest activity is required and can be obtained. Close apposition of the tubes to the active edges of the growth will ensure the best results. As many as twelve needles may be inserted into a growth. The cervix with the radium tube and needles is next carefully packed around with gauze, and the vaginal walls are protected (as far as that is possible) by being pushed as far away from the radium as possible. The vagina is next carefully packed and the requisite exposure given. At the end of the time arranged the radium is removed. It may be necessary to give the patient morphine or other sedatives during the exposure. At the end of about ten days the patient is inspected and another exposure given. Then at the end of three weeks a further exposure is made. After these three exposures the patient is kept under observation.

In a short time after the last exposure the improvement sets in, and it is no exaggeration to say that in a number of cases the immediate results of radium treatment are very remarkable. The local tumour disappears and leaves a firm pliable scar. The distressing symptoms clear up and for a time the patient returns to normal health.

In these cases a combination of radium and x rays is preferred, the latter being applied from many ports of entry around the pelvis. With the possibility of using the more penetrating x rays, of which so much has been heard lately, the prospect of helping the sufferer is greatly improved. With a skilful application of radium followed by large doses of x rays, we are almost certain to get vastly improved results. I am trying both methods singly and combined, and at present it is not possible to say which will be the more reliable method to employ in the future.

Cancer of the rectum is one of the disappointments of radium therapy; it is possible that the unfavourable results which have followed upon applications are in part due to the faulty technique. The fixation of the tube of radium is not an easy matter; great skill is required to get it into a position where it will exercise a maximum effect. It is suggested that if the growth could be brought into view by dilating the rectal canal, radium needles could be buried in the mass. In this way the irritation of the rectal mucosa would be to a large extent avoided. Long exposures would then be possible. A large number of small needles could be introduced at regular intervals of space in order to get a uniform irradiation. The aim of the treatment is to induce throughout the tumour a degree of reaction which will result in the absorption of the tumour mass. How this is brought about is not clearly understood, but it is quite clear that if a uniform irradiation is obtained the probability of favourably affecting the growth is greater.

A physician, who ought to have been better informed, has stated that radium had proved to be a failure, and that surgeons were giving up its use and turning to penetrating x rays in the treatment of malignant disease. This is not true at all, though it may have a semblance of truth in it, because so many disappointing results have followed the use of radium in quite unsuitable and hopeless cases. The failure of radium in those cases is not surprising; and need it be pointed out that radium merely follows upon failure of all other methods of treatment which have no doubt been tried in the cases sent for radium treatment?

Against this statement may be advanced the conclusions of an experienced observer, Professor Frankl of Vienna, who recently lectured in Dublin on the subject of x rays and radium. An abstract of his paper was published in the *Lancet* of December 3rd, 1921, p. 1176:

Professor Frankl pointed out that radium had a limited area of action not exceeding 4 cm., and that its effectiveness decreased in ratio to the distance, so that the peripheral portions of a tumour might receive a dose inadequate to destroy but sufficient to stimulate the cancer cells. All the cells of the body were, he said, sensitive to x rays or radium, but cancer cells and the specific cells of the ovary more sensitive than others, so that it was possible to destroy tumour cells and the follicles of the ovary without harming the surrounding tissues. Some gynaecologists had, perhaps, expected too much from rays and radium in the treatment of cancer of the neck of the uterus; there was no excuse for abandoning the knife, and a combination of the two methods promised to give better results than either alone; it was important to subject cases operated to subsequent treatment by rays. It was also true that in a small percentage of cases treatment by rays might render an inoperable case operable, or even bring about cure. In Frankl's clinic, of 42 cases of inoperable cancer of the cervix even had been cured, and 58 per cent. of the cases subjected to ray treatment subsequent to operation remained well for a period of five years. In uterine haemorrhage due to the presence of myomata or unconnected with obvious signs of disease the rays acted upon the follicular elements of the ovary, and by destroying them brought about a cessation of ovarian secretion and so produced amenorrhoea. It had been suggested that small doses might stimulate the follicular epithelium of the ovary and so cure obstinate amenorrhoea.

I am in agreement with Professor Frankl in practically all that he says in regard to radium and cancer. The probability is that in time we shall arrive at a correct estimate of the value of radiations in treatment. The five years given by Professor Frankl as the longest time up to the present he has patients in good health after x -ray treatment is not long enough on which to base values. I could quote a large number of cases of malignant disease who have had operations and x -ray treatment who are at present quite well. A number of cases in which recurrence has shown itself within the five years period have cleared up and remain well. On the other hand, it is just at the five years limit that I would look out for manifestations of deep-seated secondary deposits, and I would place the critical period upon which statistics may be based, which would be of value, between five and ten years. It is between these times that the end stages of malignancy will show themselves. I mean particularly in reference to carcinoma, for I believe that sarcomata have a much shorter latent period between the discovery and the removal of the primary growth and the deep-seated recurrence.

If and when we can produce statistics, either operative or radiotherapeutical, which clearly show a good percentage of patients alive and well ten years or longer after operation or treatment by radiation, it will be possible to consider the advisability of making statements of curative work in cancer.

It has been my fate to watch a large number of cases of cancer in all parts of the body progress towards the end stages of the malady. These stages are not pleasant ones to contemplate, and they do not encourage one to become optimistic regarding the treatment of malignant disease. True, one sees an occasional brilliant result, and encouragement springs from the sight, but on the whole the results are not good. In a fairly large percentage of cases of carcinoma of the mamma the end condition is one of mediastinal involvement: that is a hopeless condition to deal with. Radiotherapeutic measures may relieve, but they never cure. The last of the involvements is the occurrence of bone metastases. These are much more common than is suspected. They are often overlooked, even in the *post-mortem* room. Radiography has been helpful in discovering these changes in bone. Bone carcinomatosis is more common than we know. It is probably the end manifestation of the cancer process, and it may be localized or very general in its distribution. Involvement of bone may occur within five years of the primary lesion, but in my experience it does not often become evident before the fifth year, and it may appear at a much later date. From the point of view of ray therapy it is a most hopeless condition. The spread of the disease is so extensive that no amount of radiation can possibly influence it for good, though temporary improvement may follow upon thorough radiation. Nor is it likely that ray therapy can prevent the spread to the osseous system unless the primary dosage can be sufficiently large to clear up the primary growth, and any possible infiltration through the lymphatics. It is quite clear that at present we are not giving anything like dosage of such quantity and quality as to influence such wide areas. I therefore plead for the extensive use of radiations from whatever source available, and I hold that in radium we have an agent which helps towards the attainment of cures, since it carries a source of very penetrating radiation into the regions

where it is most needed, and in which in a number of cases it is not possible to of x rays delivered. It is well to use of exposures as early as possible, and to g er of exposures at intervals over a period of, say, two months, and then keep the patient under observation for as long as possible. Watch carefully for evidence of recurrence; when this occurs treat it in the same way as a primary growth would be dealt with.

In advocating the use of radium by the surgeon in his operative work, it is clear that two chief points must be realized. He must have a sufficient supply of radium in suitable applicators, and he should know something of the physical properties and action of radium. The principal fields for its use in the hands of the surgeon will be in two types of case:

1. The operable case of cancer, where the whole of the tumour can be removed. Radium is used in this class at the close of the operation as a prophylactic measure. Mr. Sampson Handley is a strong advocate of this method, and he further insists on post-operative ray treatment, the combination giving the patient the best possible chance of a complete recovery.

2. The inoperable case, in which an operation for the use of the radium is justifiable. In this type of case a large field exists, for the majority of surgically inoperable cases will have to be considered from this point of view. The field is a large one, embracing as it does a variety of forms of tumour, and an equally large variety of situations.

It is evident from a consideration of the facts submitted that the possibilities of radium in the treatment of disease have not been nearly exhausted; in fact, up to the present the technique has been more or less experimental. The experience of recent years brings forth two dominant facts. The potency of radium is now acknowledged by all competent workers; it is a most valuable adjunct to the surgeon and the x-ray therapist. Indispensable to both, it is clear that a great future lies before it. To utilize radium to the utmost it is imperative that much larger quantities must be used than has been customary. Instead of talking in milligrams it will be necessary to think in grams, and to devise technique which will make it possible to use with safety much larger quantities. The larger the quantity used the shorter will be the exposure. This in itself will be an important step, particularly in regions in which the applications are not well tolerated, such as the mouth, pharynx, oesophagus, rectum, bladder, etc.

The second important point is concerned with the technique of the application. In order to obtain the maximum effect the radium must be accurately applied. The surgeon must be prepared to perform operations for the insertion of the radium. In internal regions an exploratory operation may be required to locate accurately the tumour and to place the tubes in position. Take, for example, a localized tumour of the pyloric end of the stomach which is inoperable. Is it not possible to anchor the tumour in the operation wound, insert a number of small tubes into the tumour, allow a few hours for the exposure (and with large quantities of radium used this could be limited to a comparatively short period), remove the radium tubes, and close the wound? Such measures may appear to be extreme, but is it not a desperate condition which is being dealt with? Surely it is sound practice to give the patient the chance of even a forlorn hope.

The question of radiations *versus* operation must now be discussed. In all cases, with perhaps one or two exceptions, there can be no doubt that the operative should be the first choice. In all cases where possible radium should be used at the operation, placing it in positions which are likely to contain residual cells. It is surely more logical to endeavour to check at the outset any possible residues than to await their development.

The radium exposures should be followed up by thorough x-ray treatment. The aim of radium and x-ray treatment should be to administer doses of great intensity in the hope that changes may be brought about in the tissues which will lead to the disappearance of any cancer cells.

THE Mayor of Detroit has announced a grant of 1,000,000 dollars for the purchase of the children's Free Hospital and the Michigan State Hospital to provide additional facilities for the treatment of children in Michigan. Additional contributions to the amount of 5,000,000 dollars will be made as money is needed for the development of the joint hospital.

THE DIAGNOSTIC VALUE OF LUMBAR PUNCTURE IN CEREBRAL AND SPINAL HAEMORRHAGES.

BY

WILFRED HARRIS, M.D., F.R.C.P.,

PHYSICIAN FOR DISEASES OF THE NERVOUS SYSTEM, ST. MARY'S HOSPITAL, AND TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

For some few years I have realized in increasing degree the extreme diagnostic value of blood mixed with the cerebro-spinal fluid removed by lumbar puncture. It is, of course, to be assumed that the lumbar puncture has been cleanly performed without any great difficulty or prolonged searching, as if that happens, local haemorrhage due to the prolonged manipulation of the needle may reach the cerebro-spinal fluid. The blood in such an event is liable to clot easily, and is not intimately mixed with the fluid, unless the attempt is renewed on the following or subsequent day, by which time the blood and fluid will be intimately mixed. With this exception, the finding by lumbar puncture of free blood intimately mixed with the cerebro-spinal fluid is a practically certain and invaluable method of rapid differential diagnosis of haemorrhage occurring into the central nervous system, thus distinguishing at once between apoplexy due to haemorrhage and other causes of cerebral confusion and coma—such as embolism, thrombosis, naemia, encephalitis, tumour, diabetic coma, epilepsy and general paralysis, disseminated sclerosis, heat-stroke, hysteria, and so on. The one other condition in which blood or its derivative pigments is constantly found in the cerebro-spinal fluid is severe concussion with laceration of the brain, and fractured base. Therefore in these two diseases of haemorrhage—either spontaneous, as in apoplexy, or traumatic, due to severe injury—lumbar puncture gives us at once a certain and invariable deciding indication as to whether the lesion is one of haemorrhage within the cranial cavity or not. An examination of the chief textbooks on diseases of the nervous system shows an almost uniform absence of reference to lumbar puncture in the differential diagnosis of apoplexies, though in one or two books devoted to diagnosis the point is mentioned, but not stressed sufficiently.

During the last week I have seen in consultation five cases of acute cerebral apoplexy, in which lumbar puncture showed the cerebro-spinal fluid to be intimately mixed with and opaque with blood. In only two of these cases had cerebral haemorrhage been suggested as the cause of the mental confusion or coma before I saw the patient, naemia having been diagnosed in two of the cases, and encephalitis lethargica in the other.

The history of the latter case is instructive, inasmuch as the patient lived for fifteen days after the rupture of a small aneurysm on one anterior cerebral artery.

CASE I.

Miss M., aged 44, had not been feeling well, and had a fainting attack in a Turkish bath on March 3rd, but quite recovered. On March 8th she partook of tinned salmon at supper, and was taken acutely ill shortly afterwards with recurrent vomiting and diarrhoea, though other members of the family, who had eaten of the same dish, were unaffected. As soon as the sickness began she felt a "rush of blood to the head," and a sensation of sickness, but was quite conscious, though semi-collapsed when seen by Dr. Eric Pritchard of Hampstead at 1.30 a.m. The vomiting did not recur, and next evening she felt stiffness at the back of the neck and the flushing-sensation, being drowsy but able to talk. Even on the third day, during intervals of periods of drowsiness, she would get up from the sofa and attend to business, writing cheques and letters, and was perfectly rational, though it was noticed that she had occasional visual hallucinations. Dr. Pritchard considered the case to be one of encephalitis lethargica, and a neurologist who saw her with him on the fifth day confirmed this diagnosis, although he performed lumbar puncture and found the cerebro-spinal fluid intimately mixed with blood, showing changes in colour and general appearance compatible with a history of four days in age. I saw her on the eighth day, as during that day she rapidly became worse, being comatose, with flaccid left hemiplegia, and slight rigidity and muscular twitchings on the right side. The case appeared to me as one of undoubted inveterate cerebral haemorrhage, confirmed by the free blood found in the cerebro-spinal fluid, as I have never seen the slightest trace of blood in the fluid in cases of encephalitis lethargica. Her state made it seem probable that she could not live more than a day or two, yet she lingered another week, with total flaccid paralysis, dying on March 23rd, fifteen days after the initial symptoms of the cerebral haemorrhage. Dr. Spilsbury made a post-mortem examination for Dr. Pritchard and found a ruptured aneurysm, the size of a pea, on the left anterior cerebral artery, one-third of an inch from its

origin, with considerable haemorrhage between the membranes. The blood had forced its way between the frontal lobes, damaging considerably both inner frontal convolutions.

CASE II.

In another case, a woman aged 46, the diagnosis of uraemia had been made, because the doctor in attendance had treated her previously for high blood pressure and occasional albuminuria. She was eight months pregnant, and had been taken suddenly ill when returning home about 6.30 p.m., five hours before I saw her with Dr. Woodcock, of Palmer's Green. She was then quite comatose, with slight generalized rigidity, pin-point pupils, and extremely raucous stertorous breathing. The blood pressure was then 160, the knee-jerks brisk, and bilateral extensor plantar reflexes. Lumbar puncture revealed extensive haemorrhage into the cerebro-spinal fluid, which was intimately mixed and quite opaque with bright red blood. Death occurred five hours later, but the diagnosis made of pontine haemorrhage seems probably correct.

Meningeal haemorrhage resulting from fractured base, and lacerations of the brain due to concussion, will in like manner cause bloodstained cerebro-spinal fluid, the depth of stain varying in proportion to the amount of exuded blood. The staining may be no more than a distinct yellow tinge after the lapse of three or four days, as after the third day a pigment derivative from the blood, of the nature of bile pigment, appears in the cerebro-spinal fluid, due to absorption and chemical changes in a localized collection of blood in the membranes or brain substance. This yellow pigment, appearing after the third or fourth day of an intrameningeal haemorrhage, was shown many years ago by Froin to be practically identical with bile pigment, and gives the Gmelin reaction for bile pigment, but does not give the ordinary test for blood. Thus, a small localized cerebral haemorrhage in the neighbourhood of the internal capsule or other deep area within the brain substance, which has neither reached the surface nor ruptured into the lateral or third ventricle, will signalize its presence by the appearance of this yellow stain in the cerebro-spinal fluid within three days, rather than by the appearance of free blood mixing with the cerebro-spinal fluid, as is the case with the larger cerebro-spinal haemorrhages. In fractured base and laceration of the cortex the injury may be sufficient to cause death within a week, and yet the fluid may be stained only a light yellow, with never any free blood mixed with it.

Meningeal venous haemorrhage may occur from the rupture of a vein, usually into the posterior fossa, in periods of intense vascular congestion, as in men during the act of coitus, especially when performed in an abnormal position, such as when standing, and if the man is in poor health or suffering from headache at the time. Violent headache and faintness, with, very probably, vomiting, occur at once, and intense headache may persist for several days, though complete recovery is the rule after three or four weeks. Free blood in the cerebro-spinal fluid will be found by lumbar puncture during the first few days, the blood being probably recoverable within half an hour or so of a direct haemorrhage into the subarachnoid space. Venous haemorrhages may also occur upon the cortex during the severe congestion of an epileptic fit, or during the strain of violent coughing, as in whooping-cough, the blood either appearing free and intimately mixed with the cerebro-spinal fluid, or indicating its presence after the third day by the yellow tinge of bile pigment.

Spontaneous haemorrhachis, or intraspinal haemorrhage, may occur as the result of an intense muscular effort, and if the bleeding occurs low down in the spinal canal, amongst the roots of the cauda equina, the blood may clot *in situ*, and cause pain in the lower extremities, and motor and sensory paresis for years. Such a case I published in 1912 (*Proc. Roy. Soc. Med., Neurolog. Sect.*, February 15th, 1912, p. 115).

When the blood is extravasated higher up in the cerebro-spinal axis, then the mixture of blood and cerebro-spinal fluid obtained by lumbar puncture does not clot. Spontaneous haemorrhachis, with the formation of clot around one or more roots of the cauda equina, I believe, accounts for not a few cases of persistent pains in the lower extremities following a heavy muscular effort, such cases being usually diagnosed as ruptured muscle, fibrositis, or neuritis, and if the pain is in the front of the thigh the condition may be labelled "meralgia paraesthetica." Lumbar puncture would at once decide the diagnosis in such a case, possibly even one or two years after the onset of symptoms, as in the case quoted above, in which I obtained by lumbar puncture a canary-yellow fluid eighteen months after the primary attack. Another example may be given in which the lesion was almost certainly a spontaneous haemorrhachis.

CASE III.

A man, aged 61, strained his right leg in pushing a heavy iron safe with his knee. Two days later he noticed great tenderness along the front of the thigh, so that he could not bear the bed-clothes over it; the pain then spread to the calf and the sole of the foot, which has ever since for the last five years felt as if he were walking on sand or pebbles. The right foot is always cold and blue; there is no anaesthesia, but a varying degree of hyperaesthesia. The knee-jerks and Achilles jerks are unaffected.

Though lumbar puncture was never done in this case, which did not come under my observation until two and a half years after the onset of symptoms, I have no doubt that spontaneous haemorrhachis was the cause, and that lumbar puncture would have shown free blood in the cerebro-spinal fluid in the first few days, and that subsequently the fluid would have been yellow-stained, probably for months.

SIMPLE GOITRE.

BY

ROBERT McCARRISON, M.D., D.Sc., LL.D., F.R.C.P.,
LIEUT.-COLONEL I.M.S.

IN CHARGE OF THE DEFICIENCY DISEASES INQUIRY, INDIAN RESEARCH
FUND ASSOCIATION.

It may be useful at a time when the prevalence of simple goitre in this country is attracting attention to outline our present knowledge with regard to its causation. I include in the term "simple goitre" those sporadic or endemic cases often encountered in towns and country districts in England. Simple goitre is a deficiency disease due to an insufficient supply of iodine for the needs of the thyroid gland, or more properly for the needs of the body cells in the form of the gland's iodine-containing hormone. Two facts may be stated in proof of this definition: (1) Thyroid hyperplasia is readily produced by the use of diets deficient in iodine; (2) iodine in minute doses will prevent and cure goitre when administered at the proper time and season. But while theoretically goitre can, and sometimes does, arise in consequence of a deficient supply of iodine in the food, it arises more commonly in spite of the fact that there is present in the food a sufficiency of iodine. There is abundant proof of this statement; it will suffice, however, to mention in this connexion the results of one fundamental experiment. If animals be confined in dirty cages they will develop goitre spontaneously, the size of the goitre being dependent on the season of the year and the duration of exposure to the unhygienic conditions. If, however, they be confined in scrupulously clean cages of the same dimensions goitre will not arise. Since the food supply, and therefore the iodine supply, was the same in both cases, it follows that there are factors provided by unhygienic conditions of life, as in dirty animal cages, which render the available iodine in the food insufficient for the needs of the body in these particular circumstances. A sufficiency may become an insufficiency in the presence of such unhygienic conditions. Further, if an additional supply of iodine be provided, or cod-liver oil be administered, goitre will not develop in animals confined in dirty cages. This action of unhygienic conditions of life calls to mind the effect of want of sunlight in favouring the development of rickets when animals are fed on a diet deficient in vitamin A, calcium and phosphorus. The parallel must not, however, be pressed too far, for the mode of operation of the two factors—dirt and want of sunlight—differs; the parallelism is mentioned to emphasize the importance of such general hygienic conditions of life as clean surroundings and sunlight in the maintenance of health, an importance which is apt to be minimized in our search for more specific excitants of disease.

This effect of iodine in preventing enlargement of the thyroid gland (goitre) is to some extent exhibited also by free chlorine, although I am not yet certain how far this halogen prevents thyroid hyperplasia. So far as my experiments go they agree in their results with those of Marine, who found that iodine prevents both thyroid hyperplasia and goitre; but while chlorine has in some recent experiments prevented thyroid enlargement, it has not always prevented thyroid hyperplasia without enlargement. Two of the facts proved regarding the production of simple goitre may therefore be stated as follows: (1) That it may arise from an insufficient supply of iodine; and (2) that under unhygienic conditions of life, as represented by dirty animal cages, an additional supply of iodine is—in certain cases especially—

required for the needs of the thyroid gland; failing this additional supply goitre is prone to develop.

Previous work has demonstrated the importance of gastro-intestinal infection (in which may be included infection of the mouth, nose, tonsils, etc.) as a goitre-producing influence. The truth of this is now generally admitted. It is therefore reasonable to conclude that goitre develops in animals confined in dirty cages because their food becomes contaminated by their own excreta. Some animals are more susceptible than others to gastro-intestinal infection carried in this way: hence the individual idiosyncrasy both to goitre and to the size of the goitre that is so apparent in such an experiment. It would seem, then, that the second fact above referred to might be restated thus: Under unhygienic conditions of life, as represented by dirty animal cages or by bacteriological impurity of the alimentary tract, an additional supply of iodine is required for the needs of the thyroid gland—or more properly this additional supply is required in order that the gland may secure a sufficiency for its needs. If it does not secure this sufficiency it hypertrophies. It is unnecessary here to go over old ground¹ dealing with the experimental production of goitre in man and animals, and with the production of its congenital manifestations in animals by faecal material or faecal bacteria, or with the nutritive action of intestinal antiseptics in recent goitres. What I wish to point out here is that there is nothing in the newer work which does not dovetail into the older, although it may involve some reconstruction of ideas and a wider outlook regarding the combination of causes which gives rise to goitre. Before outlining these causes the most recently discovered fact may be referred to—namely, that excess of fat favours the development of goitre. Briefly expressed, this excess involves an additional strain on the resources of the thyroid gland, and may in consequence be a determining factor in goitre production. Its effect is more marked in some cases than in others, and is more apt to manifest itself in the presence of unhygienic conditions, such as are provided by dirty animal cages or pens, and by an unhygienic alimentary tract. Here, too, the fat excess increases the needs of the thyroid for iodine, and the goitre-producing influence of fat excess can be counteracted by increasing the available iodine in the food.

It is obvious, therefore, that the factors which give rise to goitre centre round the supply of iodine and the needs of the thyroid gland for iodine. Now this supply of iodine is dependent on a multiplicity of factors both extrinsic and intrinsic to the body. It is dependent on the iodine content of the food and water; and this in its turn is dependent on altitude, distance from the sea-coast, and the iodine content of the soil from which both vegetable foods and water derive their iodine supply. Again, the supply of iodine to the thyroid gland, and of the gland's iodine-containing secretion to the body cells, is dependent upon the adequate absorption and assimilation of iodine; this in its turn is influenced by factors such as disordered function of the gastro-intestinal tract and bacterial intervention in the digestive tube, both of which may interfere with the adequate absorption and assimilation of iodine. On the other hand, the needs of the thyroid for iodine are dependent on the needs of the body-cells for the active iodine-containing principle of the gland, and these in their turn are dependent upon a multiplicity of factors such as food balance (excess of fats, for example, increasing these needs), metabolic variations, age, sex, puberty, sexual activity, pregnancy, menstruation, infectious, and season. There is further to be considered the capacity of the thyroid gland to utilize iodine and efficiently to manufacture its hormone; here are involved such factors as heredity and excessive stimulation of the gland, which may be induced by nervous, toxic, or infectious influences, and impairment of its function, which may be induced by hereditary influences or by toxic or microbial agents, the two last being frequently of gastro-intestinal origin.

These, then, are the chief known factors—physiological, nutritional, metabolic, toxic, infectious, and nervous—which in varying combinations may cause goitre. So it comes about that while theoretically goitre may arise in consequence of actual deficiency of iodine in the food, it is much more likely to arise, and usually does arise, when a number of factors combine to render the available iodine in the food relatively insufficient for the needs of the body under the condition of life in which it finds itself. While, therefore, simple goitre is due theoretically to insufficiency of iodine, it is due in practice to a combination of factors which together bring about this insufficiency.

It is this combination of factors—a combination which

may vary within wide limits in different individuals, at different seasons, and in different localities—that constitutes the true cause of goitre in any individual or locality. Indeed, while in one locality a given grouping of factors may serve to induce goitre in a considerable proportion of individuals of the same age, sex, and race, comparatively slight variations in this grouping may suffice to cause notable variations in the incidence of the malady, or lead only to its sporadic occurrence in another locality. Long familiarity with the experimental conditions under which goitre arises has taught me how subject to variation is the combination of factors that may be concerned in the production of goitre, and how different the results may be when variation has occurred in such factors as race, locality, season, climate, and hygienic conditions of life. It is often a matter of extreme difficulty to ensure in subsequent experiments precisely the same conditions as prevailed in previous ones. The fact that the experiments are carried out at different seasons of the year or in a different place, or that in one experiment the animal cages are more scrupulously cleaned than in another, at once introduces variations in causal conditions the influence of which may be paramount. The most we can do, therefore, in regard to the discovery of the cause of goitre, or, indeed, of any deficiency disease, is to determine the combination of conditions under which it arises in the particular individual or locality with which we are dealing. It is by a knowledge of these conditions and of their relative importance, by the rectification of all of them, and by refusing to confine attention to any one of them, that we may hope to prevent and cure goitre.

I have been prompted to write this brief outline of our present knowledge of the causes of goitre because this knowledge is now sufficiently definite to enable us to prevent and to cure the condition. It is pre-eminently now which need not exist in this country if such knowledge of its causation and of its prevention as we already possess be but applied. A single example in this connexion will suffice. In 1913 I demonstrated that the goitre prevalent in a large European school in India was associated with great bacteriological impurity of the water supply. So prevalent was it that 65 per cent. of girls and 45 per cent. of boys above the age of 16 years were goitrous, and a residence of seven or eight years in this school sufficed to cause goitre in 80 per cent. of the pupils. Measures directed to the purification of the water (first by iodine and later by chlorine) reduced the incidence of the disease by 50 per cent. in a period of six and a half months, and the subsequent introduction of a bacteriologically pure water supply has resulted in its complete disappearance. The prevention of goitre is a matter of attention to food and water supply, to individual and to general hygienic conditions of life, and to the varying needs of the body for iodine.

In this outline of the causes of goitre no attempt has been made to go into detail, my object being to provide a concise sketch of the present state of knowledge regarding its etiology.

DETACHMENT OF THE RETINA, PROBABLY DUE TO EXPOSURE TO LIGHT DURING AN ECLIPSE.

BY

N. BISHOP HARMAN, M.B., B.Ch. Cantab., F.R.C.S.,
SENIOR OPHTHALMIC SURGEON, WEST LONDON HOSPITAL;

AND

PETER MACDONALD, M.D. Aberd.,
OPHTHALMIC SURGEON, YORK COUNTY HOSPITAL.

THERE is perhaps no eclipse of the sun without its quota of damaged eyes. Cases of injury of the usual type were seen after the eclipse of April of last year, despite the many warnings that appeared in the newspapers of the dangers of observation with the unprotected eye. Dr. Oliver Lodge described a case in the *JOURNAL* of May 14th, 1921 (p. 701), and cases of a similar nature were related in subsequent issues (May 21st, p. 756, and June 4th, p. 837) by Dr. G. Maxted and Mr. H. W. Archer-Hall. An unusual case in which detachment of retina of one eye occurred certainly as a sequel and probably as the direct effect of the eclipse exposure has been seen by us, and it appears of sufficient interest and rarity to merit record.

The patient is a professional man, aged 54, who was in the north during the eclipse, and was seen by one of us (P. M.) on April 13th. The eclipse of the sun (annular) occurred on April 8th. He gave a history which is set out below from notes by N. B. H., on whom the chief share in the care of the case devolved.

Notes made on April 13th (P. M.) show that: Vision right eye was perception of light in the upper part (less than half of field). Vision left eye was 6/6 with a small degree of hypermetropia, about 0.5 D. The right eye showed a very extensive detachment of the retina, involving the whole of the upper half of the eye, and the detachment ballooned downwards so as to obscure the disc and macula, which could not be seen. The vessels running downwards from the disc could be seen from a point which was estimated as being about one disc's breadth below the disc.

The point of greatest interest was the relationship between the patient's looking at the eclipse and the onset of the ocular trouble. He himself quite definitely assigned his looking at the sun as the origin of his visual defect. On first thoughts this view was not regarded with favour (P. M.), but on reconsideration of his history of the onset of the disease in this case; of the fact that the etiology of detachment of the retina is not established; that a violent stimulation of the retina is known to be able to cause damage to the nerve elements of the retina; that it is not unreasonable to regard such violent stimulation as competent to set up an exudation behind the retina; that in this case there was a history of such definite violent stimulation; that exposure to light sets up exudation elsewhere—for example, blistering in sunburn—we decided that we were justified in publishing the case as one of retinal detachment due to excessive exposure to sunlight during an eclipse. Since the patient's home was in London and he desired to return thither he was referred to N. B. H. for further observation and treatment.

When seen on April 15th he stated that he viewed the eclipse with the right eye through a piece of cinematograph film, and also through a tunnel formed by his hand. Half an hour after exposure he saw sparks in the eye; the sensation was worse on the next day. Three days later he noticed that part of the sight of the right eye was obscured; the defect appeared at first downwards and then to the right side. It rapidly got worse. He stated that his eyes had always been good, but that he had an impression that the right eye was always a little less keen of sight than the left. He had seen spots in both eyes some six months ago, but the appearance was only temporary.

Left eye: Vision 6/9, hypermetropia 0.5 D = 6/6 all; Jaeger 1 with additional 2 D. Right eye: Surfaces normal, pupil slightly smaller than that of left eye; reacts to light. Fundus reflex dull. Examination showed a huge detachment of the retina as described above, but even of greater extent, for now only a narrow band of the normal lower part of the fundus could be seen. A very few fine vitreous opacities were visible. The patient was in an extremely jumpy and nervous state; he wife said he was always so.

Taking the statement of the association of the eclipse exposure with the incidence of the detachment of the retina at its face value, it seems that there was a probability of some damage to the macular region which alone would be sufficient seriously to injure vision. It therefore did not appear advisable to attempt to relieve the detachment by operation; another consideration supporting this decision was the experience (N. B. H.) that operations do not secure better end-results than the simpler treatment by rest; and, finally, the neurotic temperament of the patient and his strong aversion to operation were conclusive against it. The treatment adopted was: confinement to bed—he was not allowed up even for the natural offices; low diet, mainly slop food; elastic bandage to the one eye; blisters to the right temple on alternate nights; and a potassium iodide mixture.

April 28th. The patient says he sees more of things with the eye. The view of the normal lower part of the fundus is wider, but there is no view of disc or macula. Treatment continued.

May 12th. The great mass of the detachment has gone back, there are only patches of rugous retina, up and to the left, up and to the right, and in the macular region. The vitreous is slightly foggy. It is possible to see all the details of the disc and to trace every vessel therefrom in continuity.

May 26th. The patient says that the eye seems better. Vision 3/60. The vitreous is full of fine dust-like opacities. The retina is not quite so flat as on the last examination; there is a bulge up and outwards. Patient has come to the limit of his toleration of confinement to bed. Short walks allowed out of doors. Fuller diet given. Eye still to be bandaged. All other treatment stopped.

June 11th. A shallow detachment of about 4 D up and outwards, and some wrinkling inwards. In the macular region is a small white opaque elevation (the size of the disc) with a dark shadow under the summit; this appearance may be either due to a dimple or pigment—parallax suggests the former. Radiating outwards from the little hillock are a number of striding edges or folds which spread upwards into the shallow detachment. Disc seen

clearly. Vitreous haze much less. Vision 2/60; the wall of the room is seen clearly in all its parts; there is no sense of deficiency; fovea are regular. Bright light dazzles him.

June 28th. The small elevation in the macular region is of less size, and there are fine glistening lines radiating out from it; the striding edges that pass outwards to the remains of the detachment are sharper. Vitreous clear. Vision 1/60. Patient allowed to return to work three days a week.

August 31st. Conditions unchanged, patient working four days a week. "Eye does not bother him, but he does not see so well with it."

November. Report received to same effect.

The sequence of events may be fairly summarized as follows: 1. Severe damage to the macula consequent on exposure to sunlight. 2. A succeeding infiltration of the macular region. 3. Extension of the exudate in such quantity as to cause a gross detachment of the retina. 4. Absorption of the greater quantity of the fluid during the weeks of rest. 5. Exposure of the initial area of damage in the macula. 6. Onset of scarring in the macular region.

It is probably fortunate that operation was decided against. Had operation been performed no benefit could have accrued to the patient, since subsequent events proved that the macula was practically destroyed. It is even possible that, had operation been performed, it might have been held to be responsible for the macular injury; in any case, there would have been no certainty that the eclipse was alone to blame for this.

There are good grounds for believing that the majority of detachments succeed some injury or tear of the retina. In this case there was no such injury, unless it can be held that the damage to the macula consequent on the exposure constitutes a point of permeable tissue. It is much more likely that the accumulation of fluid behind the retina was an inflammatory collection—a suggestion to some extent supported by the gradual onset of the cloudiness of the vitreous some time after the detachment reached its full measure.

A METHOD OF PREVENTING PUERPERAL INFECTION.*

By F. H. WHYTE, M.B.,

LATE EXTERN ASSISTANT, COOMBE HOSPITAL, DUBLIN.

In making a vaginal examination or putting the hand into the uterus abnormal ascent is substituted for the natural descent, with great risk of carrying up infection. The frequency with which these apparently trivial and necessary proceedings either kill, sterilize, or are the cause of chronic invalidism is one of

the worst features of obstetrics. Auto-genous infections are rare, and cases arising from germs lying in the lower genital tract being pushed up by previously sterile gloved fingers are not autogenous. That the vulva and vagina (particularly its lower part) are septic towards the end of pregnancy is an undisputed fact. As a rule, the lower down in the tract the more numerous, mixed, and virulent

FIG. 1.

FIG. 1.—Digital funnel. 1. A diamond-shaped piece of tough white rubber 9 inches long and 5 inches wide, to cover pubis, perineum, and sides of thighs. 2. Tube part of funnel. Diameter of tube 1½ inches. Length of upper border 3 inches, lower border 3½ inches, so that free end is cut like a Ferguson's speculum. 3. Canvas covering to funnel. 4. Boy for threading tape. The manual part that the tube part has an oval section, 1½ inches and its transverse is 2½ inches, to admit border of tube is 4 inches long and its lower is of its diamond-shaped portion is 7 inches.

FIG. 2.

FIG. 2.—Repositors for digital funnel. 1. Eye through which the tube is threaded. 2. Mark, 2½ inches from eye. 3. Handle. The instrument is made from round steel about the size of No. 7 catheter. The larger repositors for manual funnel is similar, but the eye is bigger to receive the larger tube, and the mark is 3½ inches from the eye.

do the germs become. Bacteria are common also in the urine, and the germs in the bladder may frequently cause no symptoms there, but if they reach the injured uterus their behaviour may be very different. The proximity of the

* This article was received by the Editor on November 14th, 1921.

anus to the birth canal is a source of danger also. Unfortunately the vulva and vagina cannot be sterilized. The ante-partum douche is, even in cases with obvious vaginal discharge, considered dangerous.

The severity of an attack of puerperal infection depends on the resistance of the patient, the time of infection, the site of the wound infected, the extent of the wound, the virulence of germs present, their number and variety (giving an opportunity for dangerous hetero-infections and symbioses to develop). Anything which influences any of these factors favourably for the patient will considerably alter the course of an attack of infection. The danger of vaginal examination is due to the fact that germs are lifted as the fingers touch the vulva and vagina and are carried higher up the genital tract, some being deposited on the cervix. The space between the fingers makes an excellent receptacle for carrying up the highly-infected mucus and epithelium from below.

In putting the hand into the vagina, folds in the skin of the vulva and mucous membrane of the vagina are opened up and septic epithelium and mucus are forcibly rubbed on the gloved hand. Even the anus and external urinary meatus may be so invaginated that the lower and upper borders of the hand are infected from these sources also. These are factors which assist in making the removal of adherent placenta the most dangerous proceeding of obstetrics.

The method I wish to explain depends on the fact that the germs present and unsterilizable on the walls of the lower genital tract and neighbourhood may be passed over and not pushed higher up when making a vaginal examination or introducing the hand into the uterus. The articles required are two funnels and a repositor as in the accompanying sketches.

The smaller funnel for vaginal examination is used as follows, no upward friction between it and the vagina taking place during its insertion. The boiled funnel is smeared with sterile vaseline or sterile soap solution on the surface towards which the tube part lies, or merely on the outer side of the tube. The tube is threaded into the eye of the repositor, as seen in Fig. 3. (The eye of the repositor is such that it is almost filled by the tube.) The funnel is then placed directly opposite the vulva, the labia are separated a little if the patient is a primipara, and the tube is made to enter the vagina as an intussusception by pushing the repositor downwards and backwards into the vagina. (See Figs. 3 and 4.) By this means, as any part of the funnel comes in contact with the genital tract it remains at that level, and therefore does not move any germs present in an upward direction but only turns them aside.

The repositor is only pushed down the vagina (between the entering and returning layers of funnel) for a distance of 2½ in. or up to the mark on the back of the repositor. This is done so that the repositor may not catch on the upper end of the tube when being removed.

The repositor is removed and the examination is carried out through the tube, the fingers placing the upper portion of the funnel against the vaginal walls and arriving at the cervix without contact with the highly infected lower genital tract. The manual funnel is used in a similar way, but the hand itself is the repositor and is carried straight up into the uterus. If the outlet is not dilated up a larger repositor may be used. For version or incomplete abortions difficulty would be expected in repositing the manual funnel with the hand itself.

On removing the funnel the vagina is cleaner than when the funnel entered, and few of the germs are at a lower level, as some of them come away and others are drawn down a little as the tube is removed. By the use of the digital or manual funnel the fingers or hand obviously reach the cervix without contact with infection. To prove that the intussusception of the funnel does not carry up infection I carried out the following experiment on a female dissecting-room subject. Powdered starch was placed on the vulva and lower inch of the vagina. The digital funnel was inserted as described. The upper end was then caught with bullet forceps and the tube taken out again as it entered (care being taken with one finger in the tube that no slipping of the part in contact with the vagina took place). The funnel was now reversed once more, so that the part in contact with the starch was outermost again. A series of matches were dipped in tincture of iodine and the tube was touched at various spots, when it was seen that the hne reaction was only obtained at and below the level to which the starch was placed in the vagina.

I was fortunate enough to have Dr. MacLavery's permission to try it in the Coombe Hospital, Dublin, where Dr. Keelan, the assistant master there, kindly took the matter in hand. The first patient we examined was in the gynaecology side. We found that the small funnel could be

inserted without difficulty or annoyance to the patient, and the examination of her pelvis was quite easily conducted through the tube. Since then Dr. Keelan has tried it repeatedly in gynaecological, maternity, and abortion cases. He tells me that he found it applicable, easily worked, and sound in principle; its introduction was not resented by the patients, and examination through the tube was quite easily conducted.

Occasion has so far not arisen in which to use the manual funnel, so it is with some reluctance that I publish this

method without having tried what may be the best part of the idea; but by the advice of others who have seen it and foresee its useful possibilities I am doing so now. The types of cases in which the funnels may be used are many and varied.

The small funnel would be suitable for (1) the ordinary ante-partum vaginal examination. (If repeated examination is

probably necessary in watching the progress of labour, a bandage may be tied above the trochanters and the funnel retained in position by tapes fastened to the bandage. A sterile cloth is tucked over the funnel, and so repeated examinations may be made without a summation of risk.) (2) The examination and treatment of early abortions. (3) A douche may be safely introduced through the tube in treating post-partum haemorrhage.

The large funnel may be used in (1) internal version; (2) rotation of occipito-posterior or mento-posterior presentations, the alteration of brows, etc.; (3) the removal of adherent placenta; (4) the exploration of the uterus in post-partum haemorrhage; (5) plugging the uterus for post-partum haemorrhage.

A funnel, in fact, may be used in most of the abnormal derangements of pregnancy where a finger, hand, or instrument is to be introduced into the vagina or uterus. Large instruments, as forceps, are an exception, particularly low forceps.

My apology for publishing a comparatively untried method of preventing puerperal infection is the frequency of that condition, and the hope that anyone who may chance to think the method advantageous to his patients may adopt it at once. The length of the tube portions of the small funnel (in particular) may, of course, be cut shorter to suit the length of the fingers of any hand. Messrs. Mayer and Phelps have made very suitable apparatus for my purpose.

VALENTINE MOTT'S ANEURYSM NEEDLE FOR LIGATURE OF THE INNOMINATE AND SUBCLAVIAN ARTERIES.

BY ALBAN H. G. DORAN, F.R.C.S.

CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL.

My attention has recently been directed to Sir Charles Ballance's four cases of ligature of the innominate artery published in the JOURNAL last December (vol. ii, 1921, p. 1033). I am at present engaged in the preparation of a descriptive catalogue of the collection of instruments in the Museum of the Royal College of Surgeons of England, and only a few weeks ago I came across a neat little wooden case, measuring over seven inches in length, over an inch in breadth, and under three-quarters of an inch in depth. It is covered with bright red leather, its interior is lined with dark purple velvet, and the inner surface of the lid with light purple silk, padded. The lid is united to the case by the leather covering, without any metal hinge, and is closed with two hooks and eyes, one near each end of the case.

The two instruments described below are fitted accurately into "shapes," while a space at one end of the case, covered in by a lid made out of the velvet lining, is set apart for some waxed flaxen ligature thread wound round a piece of card. Mott, in his notes in Velpeau's work, states that in these operations on the great arteries he preferred "the small

FIG. 3.—The funnel and repositor in position for introduction to vagina. The angles of the funnel are held against the resistance of invagination of first portion, and then they are turned towards the patient as in Fig. 4.

FIG. 4.—Small funnel half introduced. On removing the repositor it is necessary to introduce a finger to keep the tube in position.

strong ligatures of silk or flax." The ligature employed in his operation on the innominate artery in 1818 was silk. Raw silk and catgut, Mott adds, proved less satisfactory.

On the outside of the lid of the case is the following inscription, in Gothic letters, gilt:

Dr. Mott to Bransby B. Cooper.

The dealer's name and address, gilt, but in roman type, is marked on the case, below its line of closure with the lid:

W. L. CARTER, COUTELIER DE LA MARINE ROYALE, PLACE DE L'ODÉON, 4, PARIS."

The MS. catalogue of this collection describes the instruments in question as "Mott's apparatus for ligaturing the subclavian artery, given by Professor Mott to Bransby Cooper, by whom it was presented to the donor." Then follows the donor's name and date of presentation: "J. Birkett, Esq., 1904." No further notes are preserved.

The two instruments in the case are a special mounted aneurysm needle and what Mott calls "the American aneurysm hook."

1. *The Mounted Aneurysm Needle.*—Its total length is 6½ in. or 15.5 cm. The metal part to the bend, quite straight, is 3½ in. or 7.9 cm., and the curved portion, measured by the curve, 1 in. or 2.54 cm. The stem is inserted with a highly ornamental flange into an ivory handle, chequered on its upper and lower surfaces, and rounded off into a blunt point at its free end. This needle is moderately stout and well curved at the end, where it is blunt. At about 1/8 in. or 0.3 cm. from the end lies the eye for the hooked blade, a slit about 3/16 in. or 0.4 cm. long. A second eye, made for the ligature, somewhat smaller than the other, lies in the stem just below the bend, and about a quarter of an inch (0.6 cm.) lower it unscrews from the rest of the stem. The screw is so finely fashioned that the junction is easily overlooked; on that account it is intentionally made more visible in Fig. 1.

2. *The American Aneurysm Hook or Hooked Blade.*—This instrument measures altogether 5½ in. or 14.6 cm. The metal part is 2½ in. or about 6 cm. long. The length of the blade is 3/16 in. or 0.4 cm., the depth 1/8 in. or 0.3 cm. The stem and the ivory handle are similar in pattern to the corresponding parts in the aneurysm needle. A small, flat, blunt, hooked blade projects at a right angle from under the free end of the stem, and is fashioned out of the same metal.

Valentine Mott, in his translation of Velpeau's *New Elements of Operative Surgery* (New York, 1851), vol. ii, p. 306, describes how he ligatured the innominate in 1818:

"The artery was denuded and kept free from pleura with the aid of a scalpel; a round silken ligature was then readily passed around it."

At page 311 Mott describes the passage of the ligature:

"With the ligature introduced into the eye of one of the smallest blunt needles, which was nearest the shank of the instrument, I pressed down the cellular substance and pleura with the convex part, and very carefully insinuated it from below upwards under the artery. The point of the needle appearing on the opposite side of the artery, I introduced the hook into the other eye of it, then, unscrewing the shank, the needle was drawn through with the utmost facility, leaving the ligature underneath the artery."

The last sentence, printed here in italics, explains the meaning of the needle detachable from its stem, and the hooked blade. Mott (loc. cit., p. 301) writes: "For passing the ligature we have always used the American aneurysmal hook, which we consider the best that has ever been invented." According to a footnote it was devised by Drs.

Parish, Hartshorne, and Hewson, of Philadelphia, about the beginning of the nineteenth century.*

These contrivances were found necessary on account of the difficulty of operating on the great arteries before the introduction of anaesthetics. The patient's neck could not be held steady, and the contraction of its muscles gave great trouble to the operator and his assistants. Resection of part of the clavicle or sternum to gain space was never attempted. The ingenious mechanism by which the needle was detached and drawn out with the hook overcame the disadvantages of manipulation of the needle and ligature when a long stem remained undetached.

The case of ligature of the innominate artery ended fatally on the twenty-sixth day, but Mott met later on with great success in operations for the ligature of the subclavian. He published a "Case in which the Right Subclavian Artery was tied just as it passes the Scaleni Muscles for an Aneurysm of the Axilla from a Gunshot Wound" (*New York Journal of Medicine and the Collateral Sciences*, vol. iv, 1845, p. 16); the case is also related in Mott's notes in his translation of Velpeau's standard work. In the original report Mott, it is necessary to bear in mind, states that—

"An aneurysmal needle, armed with a strong silk ligature, was now passed round the vessel, the point of the needle being now directed outwards and backwards; so as to avoid the subclavian vein. The artery being then tied, the edges of the wound were brought together by two interrupted sutures."

No note of this special needle and hook is to be found in the 1845 report; where Mott states that—

"It was the fourth where he had put a ligature around the subclavian artery above the clavicle on the acromial side of the scaleni muscles. All the operations have been attended with success."

However, we may conclude that he held that the use of the special detachable needle and "American aneurysm hook" was a mere matter of detail, well known to his colleagues in the city where the journal containing the report was published, whilst in his additions to Velpeau's work he thought it advisable to give a detailed description of those elegant and ingenious appliances. Again, it seems that Mott presented them to Bransby Cooper as instruments for the ligature of the subclavian. In short, Mott probably used them as a rule, if not always, in such operations on these great arteries.

It is instructive to read the opinion of a great contemporary surgeon, Robert Liston, on ligature needles for large arteries. In the fourth edition of his

Practical Surgery, issued in 1846, the year following the publication of the case of ligature of the subclavian artery, at page 199, Liston states:

"The simple needle will answer the purpose [of passing a ligature round an artery at the root of the neck]; but in case of difficulty arising in consequence of the depth of the wound, it is well to be provided with a very admirable instrument, invented and manufactured by Mr. Weiss for the purpose of surrounding deep arteries by ligatures, or we may employ the needle used by my friend Dr. Mott, who was the first to practise this operation. Each is so contrived that the point, after having been felt under the vessel, can be laid hold of and detached from the stalk of the instrument. The contrivances by which this is effected are simple and ingenious."

* We think that Valentine Mott, in turn, deserves a second footnote expressing some commendation of that great surgeon for his graceful recognition of other men's work. He also had recently made it known that it was Cockell of Pontefract, and not himself, who invented that well known modification of Paré's and Scultetus's bone-saw which always goes by his name (see Hey's *Practical Observations in Surgery*, 1803, p. 8). The College possesses the set of Hey's saws used by himself at the Leeds General Infirmary. They were presented to the museum by Mr. Edward Atkinson in 1905.

VALENTINE MOTT'S INSTRUMENTS FOR LIGATURE OF THE INNOMINATE AND SUBCLAVIAN ARTERIES.

FIG. 1.—The mounted aneurysm needle. The ligature lies in the lower eye of the needle, just beyond the point where it unscrews from the stem.

FIG. 2.—The "American aneurysm hook" or hooked blade.

FIG. 3.—The hook inserted into the upper eye of the needle, which is unscrewed from its stem so that it can be drawn up by the hook, leaving the ligature under the artery.

TRICHOTILLOMANIA DUE TO THREADWORMS.

BY

HENRY C. SEMON, M.A., M.D., M.R.C.P.

PHYSICIAN IN CHARGE OF THE SKIN AND VENEREAL DEPARTMENTS,
ROYAL NORTHERN AND HAMPSHIRE GENERAL HOSPITALS;
DERMATOLOGIST TO THE MINISTRY OF PENSIONS.

Though the psychic perversion of hair avulsion (auto-epilation) cannot, strictly speaking, be classified amongst diseases of the skin, it is not infrequently referred for treatment to a dermatologist. Hallopeau first described the habit and suggested the name of trichotillomania at a dermatological demonstration in Paris in 1889,¹ and in this country Pernet² has twice shown cases at clinical meetings. The literature on the subject is mainly French (Voisin,³ Féré,⁴ Raymond,⁵ Dubreuilh and Magne,⁶ and Crutchet⁷). A detailed description of the disease, with six cases of his own (seventeen in all), was published by Wolters⁸ in 1907, and in this monograph the etiology is very fully discussed.

According to the majority of these authors, the perversion may be associated with epilepsy, general paralysis of the insane, and imbecility, and is fairly frequently observed in asylums and institutions for the demented.

The hair of the moustache and of the eyebrows may be abraded reflexly and epilated, as a result of pruritus, and the habit of tearing the hair occurs also, as is well known, in hysteria, and has been observed in epidemic form in religious revivals and other exalted or depressed conditions of the mind.

So far as I am aware, however, the etiology which undoubtedly produced the "tic" in my patient has not been recognized hitherto. Although certain associated symptoms such as nail-biting, pruritus, convulsions, tumidity of the stomach, etc.—well-known accompaniments of helminthiasis—are described by the French authors enumerated, in some of their cases of trichotillomania the possibility of oxyurias as a common cause for them all does not seem to have occurred to any of them.

Mrs. C. brought her son to me for consultation on February 8th, 1922. He is six years old, and has never had a serious illness, although he looks pale and delicate, and has a coated tongue. Both parents are normal, and there is no history of hereditary disease on either side.

The boy was first noticed to pull out his hair when three years of age, and the habit had become severe enough to produce the considerable disfigurement illustrated by the photograph. The scalp is noticed to be denuded mainly in the left frontal area, and epilation was mostly with the right hand, and at times quite subconscious, so that the child would simultaneously "play with a toy with his left hand and pull out his hair with the right." The habit was not practised during sleep, and there was nothing to suggest that local pruritus in any way disturbed him. Latterly he had been turning his attention to his mother's hair.

The scalp itself appeared to be somewhat deficient in sebaceous secretion, but was not otherwise abnormal or irritated, and the hairs which I epilated (without protest) showed no evidence of dystrophy or other nutritional disturbance.

I was assured that the boy was quite bright mentally, and took a normal interest in his surroundings. Drugs prescribed to "quieten the nerves," and punishment, or threats directed against the continuance of the practice, had all proved unavailing. Inquiry elicited the fact that the appetite was exceedingly capricious, and that threadworms had been noticed in the stools, and treated ineffectively from time to time since the age of eighteen months. The indications were obvious, and the anthelmintic treatment recommended by Still⁹ was instituted at once.

On February 22nd the mother reported that the "hair pulling" had ceased. Relapse has not occurred to date (March 25th), the anaemia and appetite are improving, while the risk of reinfection by unhatched ova is being obviated by the continued administration of iron sulphate (Still).

Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF INFLUENZA BY SALICIN.

DURING the recent epidemic of influenza I treated 54 cases by the administration of large doses of salicin—20 grains every hour for twelve hours, and then 20 grains every two hours for the next twelve hours. The ages of these persons ranged between 74 and 16 years. Four when seen had a temperature over 104°. The next day (with one exception, when the temperature was 99°) all the patients were normal or subnormal, and remained so; they were up and about the house the day after. There were no complications or sequelae. Ten had temperatures of over 103°, of whom one the next day was 99.2°; the rest were normal. They ran the same course exactly. Thirteen had temperatures of over 102°, and were well in two days. One of these, however, after going out, developed an attack of follicular tonsillitis, to which he is very subject, and which ran its usual course to complete recovery. Twenty-two had temperatures of over 101°, and 15 over 99°. They all rapidly recovered without any drawback. In no single instance was there any bronchitis or pneumonia, nor was there any mischief left behind. The attack of tonsillitis though post can hardly be considered proper influenza, as on several previous occasions this person has been treated for that complaint; and he had been out at his work for four days before starting it. These 54 cases follow in direct sequence more than 3,000 others which have been treated since 1891 in the same manner with the same results: no ill effects from the salicin; no complications; no sequelae; no deaths.

E. B. TURNER, F.R.C.S.

GONOCOCCAL SEPTICAEMIA.

The following case goes to prove that gonococcal septicaemia or pyaemia must occur, otherwise secondary infective involvement of other parts of the body away from the usual point of infection could not take place. In the case described below positive blood cultures were obtained on two occasions and on each a skin rash appeared which it was thought might possibly be associated with this condition.

A man, aged 38, was admitted to the surgical wards at the Paddington Infirmary with acute synovitis of the right knee. A history of gonorrhoea three months previously was supported by the condition of the prostate, which was hard, tender, and nodular; the seminal vesicles were palpable. He ran a temperature of from 102° to 104° F., and appeared more toxic than the local conditions warranted. The knee gradually settled down under treatment.

About two weeks after admission intense pain occurred over the outer side of the right thigh. This pain appeared to be localized to the deep fascia, and an acute metastatic involvement of this structure was considered probable. A few days later venous thrombosis occurred in the superficial femoral vein of the right leg about the middle of the thigh, and the leg became very oedematous. Gentle prostatic massage yielded pus and blood from the posterior urethra, and gonococci were found in the smear; previous examination had been negative. A generalized adenitis throughout the body then occurred. The cervical glands in the anterior triangle of the neck were visibly enlarged, and were tender on palpation, and a free purulent discharge from the urethra commenced.

Ever since admission the patient's temperature had ranged from 102° to 104°, and about three weeks after admission his general condition was much worse. His pulse rate rose at times to 140, and he had frequent rigors, but neither at this time nor in the subsequent course of the disease was there any clinical evidence of endocarditis. A papular eruption appeared at this stage. It was most marked on the extensor surfaces of the forearms and backs of the hands, and on the legs below the knees; large hyperaemic spots were also present. These eruptions faded away in the course of a few days. The next complication was the sudden onset of severe pain over the localized area in the region of the internal semilunar cartilage of the left knee-joint. There was no fluid in the joint then, but a few hours later the joint was hot, painful, and tender, and was fully distended with fluid. Epididymitis of the testicle followed next day, and the right testicle became similarly involved a few days later.

Another crop of papules then appeared, associated with large hyperaemic spots half an inch in diameter as before. A blood culture at this time gave a pure culture of gonococci, from which a vaccine was prepared. The rash disappeared in about three days, and with its disappearance there was a slight improvement in his general condition. A week later another series of rigors occurred, associated with a high temperature and prostration. Hyperaemic areas and papules appeared on the arms. Blood culture was again positive for gonococci. One papule on the hand formed a pustule, but no growth of organisms was obtained from the pus. During the course of the disease arthritic pains and

slight effusions into practically all the joints of the body took place.

Gradual recovery followed, and the temperature was normal about four months after admission. The patient was discharged to the country about two weeks later, with no disability other than a definite involvement of the prostate gland and seminal vesicles, and considerable oedema of the right leg when up and about. Three months later he reported much improvement in general health, but there was still marked oedema of the right leg, with dilatation of the superficial veins. The prostate and vesicles were in the same condition as on discharge, and he is now undergoing treatment for this.

The case seems to be worth reporting in view of the excellent recovery in spite of the very widespread involvement and septicæmia (in the absence of endocarditis). The existence of gonococci in the blood stream, and the rash, which appeared to correspond in time with the rigors and septicæmia, seem also worthy of note.

I wish to express my indebtedness to Dr. G. P. Richardson, of the Inoculation Department of St. Mary's Hospital, for the bacteriological investigation, and to Dr. Stewart, medical superintendent of Paddington Infirmary, for permission to publish the case.

JAMES A. JENKINS, F.R.C.S. Eng.

Paddington Infirmary, London.

ACUTE DIFFUSE NEPHRITIS IN CHILDREN.

ACUTE diffuse nephritis in children is a comparatively rare disease, and in severe forms the symptoms are often not marked, whilst dropsy is rarely present, so that unless the urine is examined as a routine the condition is very often overlooked. Some cases, in fact, present symptoms not typical of the ordinary symptoms of nephritis, consequently the condition at first is frequently attributed to some other disease. For this reason the recording of the following case may be of some value.

A girl aged 9 was sent to this hospital on July 4th, 1921, as a case of acute appendicitis. She was undoubtedly suffering from abdominal pain, and had vomited several times that day. I noticed, however, that the pain was confined to the "umbilical region," and that there was no distension or rigidity anywhere. No tenderness was felt in the right iliac region on palpating deeply. The patient was in a state of apathy, the temperature was 103° F., the pulse rate 140, the respiration rate 36. Dyspnoea was very marked, but there was no sign of pulmonary disease, and no cyanosis. The absence of dropsy was a feature of the case. No rash was noticeable on the body. The tonsils were not inflamed, and there was no enlargement of the glands round the angle of the jaw. No specimen of urine was obtainable at the time of admission; when the father attended on the following day he stated that a week before admission the child ceased to micturate for thirty-six hours, and then the legs became swollen. On the following day micturition started again, and the swelling in both legs suddenly disappeared, but the child began to be sick every time she took food, and the bowels were very loose. The father was very emphatic that this condition commenced suddenly, and that she had never been ill before.

During the night after admission to hospital the patient vomited several times, and the bowels moved frequently, the stools containing a good deal of mucus. The following morning the temperature fell to 99° and the pulse rate to 120, but no change in the general condition of the patient was noticeable. Alkaline and saline injections were administered, but they were not retained, and the vomiting and diarrhoea continued. It was only on the third day that a specimen of urine could be obtained. It was dark in colour and acid in reaction, with a specific gravity of 1020. Albumin was present, but not in a large quantity; no blood was detected; casts, chiefly hyaline and granular, were detected, also diacetic acid. On the fourth day the temperature became subnormal and the pulse almost imperceptible, and the girl seemed beyond any hope of recovery. On the fifth day the temperature rose to 102°; it became normal next day, and thereafter so continued, whilst the pulse improved. Vomiting did not cease until the tenth day and diarrhoea continued a few days longer. Soon afterwards herpes broke out on both hands and feet, the latter being affected most. The herpes lasted a little over a week, and on its disappearance convalescence became rapid, and she was discharged on August 21st last in a healthy condition. The urine was examined daily during the last few days before her discharge and found normal in colour, reaction, specific gravity, and quantity, without a trace of albumin. Since her discharge she has attended at the hospital several times, and has kept in good health. After the disappearance of the acidosis I relied on epinephrine, as recommended by Borelli in the treatment of this form of nephritis. Epinephrine (1 in 1,000) minims 4, with water to 1 drachm, was given every four hours, and, as can be seen, the result was most satisfactory.

The case presented many peculiar and interesting features:

- (1) The sudden suppression of urine for thirty-six hours a few days before the girl was brought to hospital.
- (2) Dropsy, following the suppression of urine, first in one leg and then in both legs. The sudden disappearance of dropsy when patient commenced to micturate again. It is also of interest to note that no sign of dropsy was noticed by her

family doctor in the face and hands, as is usually the case. (3) The colitis was the only complication noticed, and its severity was exhausting. (4) The appearance of herpes after convalescence had begun. The case shows the difficulty of coming to a diagnosis in severe forms of acute diffuse nephritis. Two years ago I saw a case of this kind in a girl of 16, in whom the main symptoms were vomiting and pain in the epigastric region; she was sent to hospital as a case of gastric ulcer, but examination of the urine afterwards showed the way towards a correct diagnosis.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

NORTH LANCES AND SOUTH WESTMORLAND BRANCH.

A VERY successful meeting of the North Lanes and South Westmorland Branch of the British Medical Association was held on April 5th at the Furness Abbey Hotel, Barrow-in-Furness, presided over by the President, Mr. A. S. BARLING of Lancaster. Dr. ALEXANDER read a short paper entitled, "A plea for earlier diagnosis of glaucoma." He outlined the symptoms of acute and chronic glaucoma, and laid stress on the necessity of quickly deciding whether a case was one of glaucoma, so as to avoid the tragedy of condemning a patient to blindness through neglect or faulty treatment. He stated that this disease constituted 1 per cent. of all eye diseases. The necessity for instillation of eserine and avoidance of atropine was pointed out. The various operative procedures were briefly noted, and the paper was illustrated by a diagram.

Dr. DEAN stated that after twenty-five years' experience he decided in favour of Hnbert's small flap operation, even although Elliot's trephining operation was the more popular. He was more and more driven to the conclusion that all operations were palliative, and the ultimate results were bad as regards sight. Dr. RUTHERFORD reminded the meeting of the fact, important to the man in single-handed practice away from help, when confronted with an acute case, that simple puncture of the sclerotic into the vitreous as far back as possible, resulting in the escape of a little vitreous, aided over the emergency by relieving pressure, and could be safely done by anyone. Dr. FAWCETT thought that in all suspicious cases the urine should be examined.

Dr. G. A. JOHNSTON read notes of a case of puerperal eclampsia which he had attended from start to finish, and frequently examined urine before and after confinement without finding any trace of albumin. The patient gave birth to twins, without any difficulty, before the arrival of the doctor, and one of the twins after birth vomited a large quantity of blood but ultimately recovered. The mother for a few days was completely blind, and the blood pressure reached 200 mm. Treatment consisted of bleeding to a pint, and the administration of chloral and bromide after initial hypodermic injections of morphine and atropine. The patient was confined on March 10th, and was now (April 5th) practically well. Dr. Johnston thought the case illustrated the toxicæmic origin of puerperal eclampsia, and he thought that the vomiting of blood by the baby was also toxicæmic. Dr. MACDONALD thought in a case like this, where there was no albumin, the faulty metabolism was probably of hepatic origin. Dr. CRAIG mentioned a case he had in which repeated examination before and after fits failed to show albumin, and yet once or twice throughout the period the urine boiled nearly solid and rapidly cleared again, so that he thought there might have been albuminuria in Dr. Johnston's case of an evanescent nature.

Dr. REED showed a child, 4 years old, with extraordinary malformation, which was present at birth. The lower limbs were enormous as compared with the rest of the body. The feet were deformed and superdilatation was present. The child moved along the floor in a shuffling, grotesque manner—right foot and left knee alternately pressing against the floor. Dr. Reed considered the condition was due to interference with development of the lymphatic circulation, and therefore akin to elephantiasis. Other interesting cases were shown by Dr. ALLAN, Dr. MILLIGAN, Dr. FAWCETT, and Dr. LIVINGSTON.

Reports of Societies.

RECOVERY IN MENTAL CASES.

At a meeting of the Section of Psychiatry of the Royal Society of Medicine on April 11th a discussion was opened by the President, Dr. BEDFORD PIERCE, on the subject of "Recovery."

Dr. BEDFORD PIERCE said that the recovery which he had in mind was recovery in the social sense—not the eradication of morbid tendencies, but the restoration of the previous state, enabling the patient to resume his former life. His remarks bore upon 120 cases of recovery which he had observed since 1908, in which year the system of registration of recoveries instituted by the Medico-Psychological Association was started. He divided these cases into five groups:

1. Relapsed cases which appeared to recover, but eventually did badly—21.
2. Cases in which the cause of recovery was obscure—27.
3. Obscure cases in which heredity might have had an important influence—20.
4. Cases in which recovery appeared to have been brought about by the removal of some physical condition—33.
5. Cases in which recovery appeared to depend upon the removal of some mental stress—19.

"It was unfortunate; from the medical point of view, that there were so large a number of cases to which no definite reason for recovery could be assigned. In some of these cases—even those with a long history—it was extraordinary how soon convalescence began after transference to new surroundings. The benefit in these cases did not appear to be due to change of climate, food, or any bodily condition, but to new personal relationships and outlook.

Continued residence in the same mental institution was not always beneficial. One lady in the third group recovered with startling suddenness. She had been ill for four months before admission, and rapidly passed into a state of stupor, in which she required to be tube-fed, and rarely spoke to anyone. Then one day she signalled her recovery by remarking to his colleague, "You have your reward." The remark referred to an observation which the doctor had made to the nurse a few days previously when attending the patient, "Well, I suppose we shall have our reward some day." The factor of auto-suggestion as a means of recovery in these cases of stupor carried one only a little way towards the understanding of their nature. It was obvious that this lady, while stuporous, continued to receive impressions, and it seemed unlikely that his colleague's remark had anything to do with her recovery.

His largest group of recoveries (8 men and 25 women) were cases in which there was definite physical disorder. Alcohol, drugs, and sedatives were responsible in 10 of these cases; the puerperium in 8; post-operative troubles in 4; influenza in 4; and in the remainder a variety of causes, including encephalitis lethargica and diabetes.

As an instance of complicating factors he mentioned one case, a woman of 44, admitted in acute confusion, six weeks after the onset of mental symptoms following influenza. The family history was bad, there was chronic financial difficulty, the woman had been addicted to self-abuse, and she had had the responsibility of nursing her parents. Her recovery was slow, but after five months' residence she was discharged, and remained well for ten years, when, following another attack of influenza, she again had mental trouble, and died in acute mania. Here there were at least five causal factors: heredity, bad habits, financial stress, the strain of nursing, and influenza, which last was probably the one of most immediate importance.

As a general rule he never gave sedatives for restlessness or excitement. It was only when the patient began to show objective signs of wear and tear that he gave them a trial. His last group consisted of persons whose recovery seemed to depend upon the removal of mental strain or the making of new mental adjustments. The psychosis in the majority of these cases was maniacal in character. In one case the attack of mania followed the bombardment of West Hartlepool during the war, after the person concerned had rendered quite heroic aid among the wounded; others were due to grief, household worries, and an unhappy marriage. The removal from home and the introduction to a new social environment did much, but a considerable time was necessary for the recovery to take effect. It was always necessary, in working towards recovery, to bear in mind the necessity for combating secondary factors. Even when the cause was psychogenic, such as thwarted instinct, there was probably an induced toxæmia or a disturbance of the balance of the secretions. Recovery from the psychosis was due, at least in part, to the removal of the associated physical disturbance. Psychiatrists must be eclectic in their methods of treatment, and must not

identify themselves with any single method. The mechanism of recovery after all was as obscure in the case of measles or herpes as in delirium or melancholia. The statement often made by those who belittled the success of psychotherapy that it lagged behind general medicine was unfair in view of the inherent difficulty of psychological problems.

Sir ROBERT ARMSTRONG-JONES differed from the psycho-analytic definition of insanity which Dr. Pierce had given—namely, as the withdrawal or retreat from an intolerable situation. He said that in every mental case it was impossible for the person to know what he was escaping from or was trying to escape from. As for the percentage of recovery, in his own experience at Claybury, which extended to nearly a quarter of a century, the recoveries were 33 per cent. Some cases recovered after fifteen or twenty years or longer. The proportion of recoveries was noteworthy among cases which had been transferred to Claybury from a private asylum; this meant no reflection upon the private asylum, because the factor at work might simply have been a fresh social adjustment. He thought that cases with heredity were really more recoverable than cases with no hereditary history at all. Many people were discharged from asylums as recovered, and yet for many months, or even years, were quite unfit to manage their own affairs. One of the greatest factors in recovery was undoubtedly auto-suggestion, which was the same thing as had been described by Chalmers, the great divine, as "the expulsive power of a new affection."

Dr. C. HUBERT BOND said that it had lately been resolved by the Board of Control that medical staffs of mental hospitals should supply copies of their recovery registers to the Board in the same way as, for many years past, they had supplied copies of their admission registers. There were about 22,000 admissions annually into institutions for the insane in this country, and the recovery rate was 33 per cent. But that recovery rate was obtained by including all cases, and it was only fair to eliminate certain groups, such as true senile dementias when clearly diagnosable, also congenital cases which were in a state of idiocy or imbecility, though not the milder forms of congenital mental defect, because upon such a condition there was often superimposed an acute psychosis from which the patient recovered and was able to resume his former life. He thought also that it would be fair, in the present state of knowledge, to eliminate cases of general paralysis from this computation; he was a little doubtful as to the elimination of epilepsy. If these forms of mental disorder were eliminated the recovery rate, instead of being 33 per cent., became 49 per cent. Of the cases admitted some 37 per cent., by all the evidence of parallel cases, were recoverable, and yet for some unknown reason did not recover. The fact that these cases did not recover was a reason for closer and more routine methods of inquiry, both on psychogenic lines and in the laboratory.

Dr. STANFORD READ pointed out that what might be regarded as recovery from the social standpoint was not necessarily recovery from the strictly scientific standpoint. Many mental symptoms were physiogenic in origin, but there were others to which it was impossible to assign a physical cause. He could not think that the question of recovery had been properly considered unless the circumstances of the individual illness had been fully ascertained, and he pleaded for a more intensive study of the individual case, especially in its psychopathological details.

Dr. THOMAS BEATON doubted whether the intensive method of the study of the individual case would reveal as much as the previous speaker supposed, for the most one could get from another individual was what he chose to reveal, and there were barriers to the personality in all cases, normal and abnormal. To his mind the course of recovery had two definite stages: (1) Gradual diminution and final cessation of the actual morbid symptoms; (2) a period of what might be called convalescence (though the patient was still ill) in which an adjustment was proceeding, quite below the level of consciousness, a state usually marked by apathy, submissiveness, and lack of initiative. Time played an important part in all mental processes, including those of the normal person; in grief, for instance, there was no remedy but time; which placed the trouble in its true perspective. With regard to the physical or psychical nature of the cause they were all very much in the dark. Rather too much stress was laid upon infections, which could not be an absolute cause. Metabolic disturbances also doubtless played a part. He dwelt upon the good effects of the confusional state as a release from the previous hallucination in which the individual had been continually rationalizing and building

on the false experience. So long as that rationalizing process went on there was little hope of recovery, but when the patient became confused the intelligence was resting, and the prognosis was more favourable. He believed in the value of sedative drugs, and recalled a case in which a man had an acute hallucinatory psychosis, and was so excited owing to his vivid hallucinations that the only way he could be controlled was by giving him a very heavy sedative, with the result that he became quite confused; at the end of a week arrangements were made for his removal, and the sedative was discontinued, whereupon the man came out of his state of confusion perfectly well and able calmly to discuss the situation.

Dr. HUBERT NORMAN dwelt upon the difficulty of making returns as to recoveries in view of the possibility of relapse. He associated himself with the previous speaker in advocating sedatives. If the deeper cell layers—deeper than those disordered—could be put out of action for the time being, it gave the others, where the disorder had occurred, a chance to settle down and recuperate.

Dr. BEDFORD PIERCE, in reply, said that with regard to the origin of mental disorder, when the condition was extremely severe he could not but think that some toxæmia played a part, in addition, of course, to any psychogenic factor. He looked upon sedatives as agents which caused a slowing down of the protoplasmic activity, thereby delaying the process of repair. Sleep induced by sedatives was probably lost time, and it was better to use baths, fresh air, and other similar methods rather than sedative drugs, though he agreed that some of these last seemed to act in a marvellous manner. He was quite convinced that some cases would never recover so long as sedatives were administered. It was the theory of some physicians with whom he had been called into consultation that if the patients could only be got to sleep the maniacal symptoms would disappear. But he believed that sleep induced by sedatives would only retard the process of recovery.

THE LYMPHOIDOCYTE AND THE TÜRK CELL.

At a meeting of the Pathological Section of the Liverpool Medical Institution held on April 6th, with Dr. HILL ABRAM in the chair, Drs. J. C. MATTHEWS and C. V. PEARSON contributed a paper entitled "The lymphoidocyte and the Türk cell," giving an account of a research which had been suggested by an article which appeared in the *Lancet* (July 19th, 1919, p. 108), in which Knyvett Gordon described the discovery in the blood of cases of subacute bacterial endocarditis, and other diseases, of a cell to which he considered the name "lymphoidocyte" to be applicable. The writers investigated 225 cases of miscellaneous diseases, and failed to find the lymphoidocyte in any except those of leukaemia. Pappenheim's panoptic stain was used. A discussion was given of haematological terms and of staining methods, with the object of proving that the writers were conforming to well-recognized standards in the use of the term "lymphoidocyte." In the course of the research deeply stained basophil cells were occasionally seen in normal and pathological blood, and were considered to conform to that known as the Türk cell. Reasons were given for regarding the Türk cell as a lymphocyte which has undergone metaplasia, probably as a result of some stimulation or irritation. It was found in abnormal numbers in many conditions, in most of which generalized blood infection was present. Analysis of the findings did not suggest that it had any serious prognostic significance.

PREVENTION OF GYNAECOLOGICAL AFFECTIONS.

The Glasgow Obstetrical and Gynaecological Society met in the Faculty Hall on March 15th, with the President, Dr. J. BALFOUR MARSHALL, in the chair. Dr. W. D. MACFARLANE read a paper on some preventable causes of gynaecological affections. Ever since Semmelweis (the true pioneer of antiseptics in obstetrics) published his work on the cause, concept, and prophylaxis of puerperal fever in 1861 there had been a greater zeal in the prophylactic side of obstetric practice. Much yet remained to be done in the way of eliminating from medical practice the after-results of difficult and complicated labour, or even simple labour. The large proportion of gynaecological ailments result from the accidents, used in the largest sense of the term, of childbirth. The question for discussion that evening was how many of these unfortunate conditions could be prevented.

No young graduate (continued Dr. Macfarlane) thinks or dreams of doing a major surgical operation, and yet here in the realm of obstetrics he is forced by the nature of circumstances to do so. My plea is for a more extended course of clinical obstetrics under teachers of experience. You may say that it is not very easily obtained. I think it is. It is only a question of money; and surely where the matter is one of such importance—namely, a living mother, and very particularly a healthy mother, as well as a living child—the State should be made to take cognizance of the present position, which seems to me to be far from satisfactory. Thus I think a course of clinical instruction, equal at least to that given in medicine and surgery, is an essential if many of the gynaecological affections resulting from labour are to be prevented. Another aspect of this question is worthy of consideration—the establishment of a State, county, or municipal obstetric service. Medical men in general are not over-anxious to have midwifery cases, at least in any great number, and so the practice is coming more and more into the hands of trained midwives. I heartily welcome this change, as it makes all for prevention of gynaecological cases. The chief essentials are that the nurses are well trained in modern surgical principles, and that they are intelligent and have sufficient experience to guide them in asking for medical assistance. I hope at a future meeting to elaborate this question of an obstetric service, which would, in my judgement, be a real service to the patient and relieve a busy practitioner from the worries of midwifery, which often interferes with his other work. Labour is a natural process which requires time, and should not be hurried unless in cases of emergency—certainly not hurried to suit the other necessities of the busy practitioner. Here, as I have already indicated, is a sure means of prophylaxis.

Dr. Macfarlane then discussed some preventable causes. Of these sepsis claimed its many victims, either in the way of mortality or morbidity. In regard to the latter, many cases of minor sepsis were overlooked. The patient might make no complaint at the time, the pulse might be normal, and the morning temperature normal and perhaps the lochia a little heavy. In a few days the patient was supposed to be able to move about and soon begin her work. Going over 400 consecutive cases in his journals, he found the following statements made by the patients voluntarily: "Never well since the birth of first child"; "Ever since my miscarriage I have been ill"; "Ulceration of the womb ever since first baby." On questioning these women the puerperium had apparently been normal, but they had never been well since the full-time birth or the miscarriage. He wondered how often in general practice any attention was paid to the evening temperature—a small rise not being recorded—yet here was the indication of some minor form of sepsis as a rule. Among the 400 cases there were 118 patients who aborted, some several times—as many as twelve or fourteen times; and after excluding the possibility of syphilitic infection or abortion caused by fibroids, the great proportion were associated with laceration of cervix, backward displacement of uterus, or "chronic inflammatory mischief." Most of these cases were in some degree or other, as far as the history could help, infected to a minor degree; they were never well since the miscarriage—pain and menorrhagia being the chief complaints. The young practitioner and the nurse needed to be more careful in dealing with abortion cases. Associated with these minor and unrecognized forms of sepsis the involution of the uterus was interfered with. If the causes of this condition were more carefully searched for—namely, retained pieces of placenta or membrane, blood clot, the non-shrinking of the child—and attention paid to the treatment of constitutional disease of the mother or the results of *ante-partum* and *post-partum* haemorrhage, then this condition, which bulked so largely as a cause of so-called inflammation of the womb, and certainly the cause of so many backward displacements of the uterus, would be dealt with efficiently and the gynaecological affections prevented. In the 400 cases there were 77 cases of retroversely flexed uterus in which the cause seemed undoubtedly puerperal. Timely treatment by pessary might have made later operative treatment unnecessary. Pelvic peritonitis and accompanying salpingo-oöphoritis complicated 44 of the 77 retroflexions—an infection either by continuity of the mucous surfaces or by minor degrees of lymphatic sepsis. The untimely and injudicious use of forceps was responsible in many cases for either laceration of the soft parts or overstretching of the tissue, so that they never regained their former tone, and hence prolapsus uteri was favoured, or some perineal laceration was imperfectly repaired, the support to the anterior vaginal wall withdrawn; and this, complicated by overstretching of the pelvic floor, began the whole story of prolapsus uteri. There were some 54 cases of varying degree of prolapsus in the 400 cases, which might undoubtedly have been reduced in number by greater care and experience. That 37 severe cases of laceration of the cervix were allowed to go untreated and be associated with repeated abortions and metro-endometrial changes was

further proof of the possibility of preventing weeks or months of illness to the mother. Again, the injudicious use of the curette was responsible for quite a number of acute uterine and pelvic conditions. It seemed to be almost a universal rule to curette when in doubt in gynaecological cases. One regard was not often enough paid to the aseptis of the vaginal and cervical canal.

An interesting discussion followed, in which the Fellows present joined.

STRICTURE OF NASAL DUCT.

A MEETING of the Irish Ophthalmological Society was held in the Royal Victoria Eye and Ear Hospital, Dublin, on March 23rd. There was a good attendance, with the President, Mr. J. B. STONY, in the chair.

Mr. T. O. GRAHAM opened a discussion on stricture of the nasal duct. He said that to overcome epiphora various operations had been devised which had for their object the short-circuiting of the tears directly into the nose from the lacrimal sac. Toti advocated the transplantation of the outer wall of the sac bearing the entrance of the canaliculi into the outer wall of the nose. This he did by external operation. West, however, conceived the idea of attacking the lacrimal sac from the nasal cavity, thus dispensing with the external skin incision. Mr. Graham had adopted West's method and modified it. The operation was most easily carried out under local anaesthesia.

The area on the outer wall of the nose anterior to the middle turbinal is anaesthetized with the local application of 20 per cent. cocaine and adrenaline, or submucous injection of novocain may be employed. With a septum knife or small scalpel the mucous membrane about half an inch square is removed from this area. The underlying bone is then chiselled away, the window in the bone being enlarged by means of nibbling forceps such as Heymann's. In this way the inner wall of the lacrimal sac is exposed and can be invaginated into the nose by passing a probe through the lower canaliculus into the previously cocainized sac. While the probe thus invaginates the inner wall of the sac a vertical incision is made into its anterior surface with a fine-bladed sharp knife. The inner wall of the sac can then be removed with a conchotome. I find it unnecessary to use the special sharp-toothed tenaculum forceps for catching the sac. This completes the operation. The after-treatment consists in irrigating the sac through the canaliculus and preventing the formation of granulations around the artificial opening in the sac.

The difficulties encountered during the operation were enumerated as follows:

1. Thick bone, particularly a prominent sclerosed nasal process of the superior maxilla.
2. An overlying anterior ethmoidal cell which may be opened up. One finds then that two layers of bone have to be removed in order to reach the sac, which lies at the bottom of a recess in the lateral wall of the nose.
3. An enlarged anterior end of the middle turbinal which may require removal.
4. Haemorrhage during the operation. The operation may have to be completed under the sense of touch, a finger pressing into the lacrimal groove externally acting as a guide.
5. A narrow nose; in order to obtain sufficient space for approaching the sac it may be necessary to do a preliminary submucous resection of the nasal septum.

Mr. Graham had endeavored to ascertain by observation and inquiry letter the end-results of the thirty intranasal dacryocystostomy operations performed by him during the past three years.

Twenty-two were complete successes. Four had lacrimal sac fistula prior to operations: all healed up after the intranasal drainage of the sac. Four wrote to say that they still had epiphora: improvement; one said there was now only and no purulent discharge. Four had not inquiry; two of these patients were, however, free from trouble on leaving Dublin several weeks after the operation. All these thirty cases had been referred to the speaker for operation by ophthalmic surgeons who had carried out conservative treatment without permanent benefit.

Mr. L. J. CURTIN said his experience was not extensive, but the operation seemed to present some difficulties from the operator's point of view. (1) If the nose were narrow it was difficult to orientate properly owing to the lateral view of the site of operation. (2) Sufficient space was not always available for grasping and cutting instruments to be inserted at the same time. These obstacles could be overcome to some extent by performing a high submucous resection of the septum or by following the transseptal route. After-treatment was all-important, and it must be carried out from six to eight weeks following operation, with an occasional visit up to a later period. Granulations needed removal when they made their appearance.

In the discussion which followed the President, Messrs. WERNER, J. A. CRAIG, SMITH, DWYER, JOYCE, MOONEY, CRAWLEY, and MATTHEWS took part, and Mr. GRAHAM replied.

The following cases were shown by members:

Mr. STONY: Calcareous film of the cornea after sympathetic ophthalmia in 1915. Several cases of mucocele and stricture of the nasal duct; some of hypopyon keratitis under treatment.

Mr. WERNER: Case of tumour of pituitary and basilar process of occipital bone region. Case of skin graft.

Mr. CRAWLEY: Case of epiphora.

Miss MAXWELL: Case of lacrimal gland tumour treated by x rays and improving. Case of retinitis proliferans.

Mr. W. C. MACPETHRIDGE: Case of post-neuritic atrophy of both optic nerves in a young man, attributed to sand-fly fever.

Reviews.

PUBLIC HEALTH AND GENERAL MEDICINE.

IN his foreword to *Practical Preventive Medicine* Dr. MARK F. BOYD, who is professor of bacteriology and preventive medicine in the medical department of the University of Texas, expresses the opinion that the general practitioner is not using to the full the opportunities he has in the field of preventive medicine and public health. To bring home to medical students and practitioners, a realization of their public health responsibilities and stimulate co-operation with public health authorities is therefore one of the purposes of his book. In his endeavour to accomplish this purpose he has produced a work of unusual interest and reliability. The general arrangement differs from that usually adopted by writers of public health textbooks, and rightly so in view of those for whom it is intended, though public health students and public health officers will find in it a great deal of useful and precise information of the utmost value, including bibliographical references at the end of each chapter. More than half the volume is devoted to epidemiology; diseases due to invading micro-organisms are dealt with in a manner which cannot fail to be helpful to the practitioner who is desirous of taking his part in the prevention as well as in the cure of disease. Separate sections are allotted to deficiency diseases, occupational diseases, diseases arising from the puerperal state, and diseases transmitted from parent to offspring.

The final chapter gives a succinct account of the public health administration in the United States. In the central or federal administration there is unquestionably a great deal of overlapping, which Dr. Boyd considers can best be remedied by the creation of a single public health department. In some States, such as New York, Massachusetts, and Minnesota, there is efficient administration, but elsewhere it is said to be manifestly inadequate. Local health administration in many parts of the country appears to be subservient to political organizations, though there are many notable exceptions. Dr. Boyd anticipates improvement in this respect by means of propaganda. He refers over and over again to the importance of educating the public in matters of hygiene and sanitation, and expresses the opinion that the avenues of instruction available are "through the press, the movies, pamphlets and circulars, lectures, special conferences and exhibits, and instruction in secondary schools." The value of this work is materially increased by the inclusion in it of a large number of illustrations and diagrams and by a very complete index to its contents.

PSYCHO-ANALYSIS AND THE FAMILY.

THOUGH Mr. FLÜGEL describes his book on the *Psycho-Analytic Study of the Family*² as a compilation, the material he has gathered together is presented in a manner indicative of much personal thought and consideration. The author writes with authority as an orthodox exponent of Freud's teaching, and the volume may be recommended to those who wish to obtain a clear understanding of the principles it is intended to teach. Mr. Flügel devotes some attention to views which diverge from his own, and he appears to concede rather more than some of his colleagues to the post-analytic school, notably in respect to the interpretation of symbols.

¹ *Practical Preventive Medicine*. By Mark F. Boyd, M.D., M.S., C.P.H. Philadelphia and London: W. B. Saunders Company. (Med. 8vo, pp. 352; 135 figures. 28s. net.)

² *The Psycho-Analytic Study of the Family*. By J. C. Flügel, B.A., Senior Lecturer in the Department of Philosophy and Psychology, University College, London. London, Vienna, and New York: The International Psycho-Analytical Press. No. 3. The International Psycho-Analytical Library. (Roy. 8vo, pp. 259. 10s. 6d. net.)

The social problem considered in this volume—namely, the influence of parents on the mental development of the child—is one of much importance. This influence is possibly somewhat overemphasized at the present time, and insufficient account is taken of inborn "sensitivity," but this is a fault in the right direction, as it concerns circumstances which are capable of being modified; it must be recognized that Freud has done much to extend and formulate our knowledge of the family situation and to draw attention to its significance in relation to the future reaction of the child. At the same time there is much in the Freudian system which arouses opposition, and to which it appears reasonable to adopt an attitude of scepticism. As an instance may be cited the chapter in this volume dealing with ideas of birth and pre-natal life, where Mr. Flügel not only describes coffins, graves, and vaults as all being symbols of the mother's womb, but seriously discusses, and seems to be attracted towards, the highly speculative theory that birth fantasies may be derived from pre-natal impressions and experiences. While such views may be, and frequently have been, criticized on theoretical grounds, certain opinions expressed in this book we regard quite definitely as biologically unsound and socially undesirable. We refer more particularly to the author's discussion on forbidden marriage relationships. Contrasting exogamous communities with modern civilizations, Mr. Flügel points out that there is a tendency for the number of forbidden relationships to become smaller as culture advances. He cites as an instance the recent removal of the ban upon the marriage with a deceased wife's sister. He then proceeds as follows:

"The same result emerges if we consider the matter . . . from the point of view of . . . an enlightened system of morality. The evidence available shows, for instance, that little if any harm is likely to ensue from the marriage of first cousins, so long as the stock is a healthy one: much the same is probably true as regards the marriage of half-brother and half-sister or even full brother and sister. Our condemnation of such unions is due to influences emanating from the repression of the incest tendencies, and not to any sound appreciation or experience of their ill effects; and in so far as the taboos consequent upon repression give way to more balanced moral judgements based on a real understanding of the issues involved, . . . the disapproval of these unions between near kin will be continued only in so far as real dangers are to be apprehended from them. Among such real dangers there may be found the biological one of the possibility of inferior offspring, especially in the case of families with marked hereditary defects, and the psychological one of too little emancipation from all the family influences, with all the consequences that this may involve. As regards this latter, however, it will have to be recognized that complete emancipation will often be beyond the bounds of possibility, and that it is often advisable to permit some degree of indulgence to overstrung unconscious tendencies, so long as this indulgence is not too persistent or too definitely pathological" (p. 229).

It is most difficult to find any justification for such views. There would seem to be no ground for the contention that a more enlightened system of morality would give social sanction to incestuous relationships. On the contrary, such sanctions would seem to be more suggestive of decadence than of progress in any race or community. From a biological point of view we should have thought that experience on the whole was definitely against inbreeding, and in any case cultured people who exhibited a desire for incestuous relationships would certainly tend to be of the psychopathic type and therefore all the more liable to produce degenerate offspring. That this is so is evidenced from the fact that incestuous fantasies so often find expression in the delusions of dementia praecox. Most sociologists will probably prefer to rely on the wisdom of the ages in regard to these matters rather than on conclusions based upon the study of the unconscious needs of the neurotic.

A MANUAL OF FEVERS.

We welcome the appearance of the second edition of Dr. CLAUDE KER's excellent *Manual of Fevers*.³ The work is divided into fifteen chapters: the first two are introductory, and the rest are devoted to a consideration of the diseases usually met with in fever-hospitals—namely, measles, rubella, scarlet fever, small-pox, vaccinia, chicken-pox, typhus, enteric fever, diphtheria, erysipelas, whooping-cough, mumps, and cerebro-spinal fever. An account of other diseases which are only occasionally seen in fever hospitals—namely, influenza, poliomyelitis, and encephalitis lethargica—is omitted.

³ *A Manual of Fevers*. By C. B. Ker, M.D. Second edition. Oxford: Medical Publications. London: H. Frowde, and Bodley and Stoughton. 1922. (Cr. 8vo, pp. x+334; 35 figures, 6 plates. 12s. 6d. net.)

Although the work as a whole is a model of what a textbook intended principally for students should be, there are certain details which call for criticism. In the chapter on vaccinia no note is made of the liability of generalized vaccinia to occur when vaccination is performed on a child suffering from a skin disease, especially eczema. This is a serious omission, for neglect of this precaution has been the cause of a certain number of fatal cases. In the chapter on enteric fever no mention is made of the possibility of laboratory infection, several instances of which have lately been recorded. Dr. Ker recommends that antitoxin should not be given in relapses of diphtheria unless the symptoms are very urgent and severe; as a rule, however, the relapse of diphtheria is mild and can often be cured by local treatment only; we are not aware that alarming results of an anaphylactic nature have followed the administration of small doses of antitoxin, but it is a good rule never to exceed 9,000 units when the patient has been sensitized by a previous prophylactic or therapeutic injection. The half-tone photographs of the eruption of scarlet fever, facing p. 74, and of a scrub rash, facing p. 262, might well be replaced by colour plates or omitted, as they have no value as illustrations. In spite of these shortcomings, we have no hesitation in warmly recommending the book to medical students, especially those living in London, who can beguile their long journey to and from the fever hospital by a perusal of its pages.

A SHORT TEXTBOOK OF SURGERY.

The outstanding feature of Mr. MACEWEN's *Textbook of Surgery*⁴ is that it is small enough to be slipped into a student's overcoat pocket. Yet on its six hundred pages there are more than five hundred illustrations. This achievement (remarkable in these days of ponderous tomes and multiple volumes, and no doubt welcome to the student) is attained by the omission of "fractures and dislocations" in their entirety, and by a reduction in size of the illustrations, which nevertheless upon the whole are good; certainly when good they are useful, having been well chosen from an extensive collection.

An author to be brief must be dogmatic, and Mr. Macewen disarms criticism in his preface, though in fact he need not have much uneasiness on this score. Of course it is easy to take exception to certain statements—as, for example, that "chronic appendicitis is generally due to tubercle." Is it so certain either that "young carcinoma cells, like leucocytes, possess the power of slight independent locomotion," or that "thus" (our italics) "they infiltrate the surrounding tissues . . ."? On the other hand, the author is sometimes not dogmatic enough. When does intestinal obstruction "threaten"? And surely there should be an incisive statement about the medical man's duty when it is actually established. Such minor blemishes, however, only throw into relief the general excellence of the teaching, the sound and simple arrangement of the matter, the balanced selection of information. The book cannot fail to be popular with students.

CHEMISTRY.

The fourth editions of Mr. A. W. STEWART's two books on chemistry, *Recent Advances in Physical and Inorganic Chemistry*,⁵ and *Recent Advances in Organic Chemistry*,⁶ may be warmly recommended to the many readers who take an interest in chemical problems and are anxious to know something of the progress made year by year in chemical science. The author writes very clearly, and his pages make no very great demand on the chemical knowledge of their readers, and are free from mathematical abstractions; the subjects he has chosen for discussion in the two volumes are interesting, though naturally not all of them equally so to everybody. They should be of particular interest to all students of chemistry, for they contain answers to many of the questions likely to be set in examination papers. The author's references to some of the many unsolved problems of chemistry will serve a particularly useful function by

⁴ *Textbook of Surgery for Students and Practitioners*. By John A. C. Macewen, M.B., C.M., B.Sc. Glasgow: Maclehose, Jackson, and Co. 1922. (Demy 8vo, pp. 619; 535 figures. 30s. net.)

⁵ *Recent Advances in Physical and Inorganic Chemistry*. By A. W. Stewart, D.Sc.; with an introduction by Sir W. Ramsay, K.C.B., F.R.S. Fourth edition. London and New York: Longmans, Green, and Co. (Demy 8vo, pp. 302; 5 plates, 23 figures. 18s. net.)

⁶ *Recent Advances in Organic Chemistry*. By A. W. Stewart, D.Sc.; with an introduction by J. N. Collie, LL.D., F.R.S. Fourth edition. London and New York: Longmans, Green, and Co. (Demy 8vo, pp. 371; 21s. net.)

indicating directions in which research seems most promising or most required. It is no doubt unfortunate for the purchaser that the prices of the fourth editions of books should be about half as big again as those of the third editions, although no material increase in the number of pages has taken place; but presumably the high prices of labour and materials have left the publishers no choice in the matter.

The second volume of the third edition of Professor LEWIS's *System of Physical Chemistry* deals with *Thermodynamics*, and supplies the botanist with an introduction to the chemistry of physics with a very thorough account of the subject with which it deals. The treatment throughout is of necessity highly mathematical; the subjects discussed are in the main theoretical, although Professor Lewis incorporates what he can of practical and technological chemistry. The book is admirably turned out by the publishers and should be of great service to mathematically minded chemists.

The first volume of the *Introduction to the Chemistry of Plant Products*,⁸ by Dr. HAAS and Mr. HILL, sets out to furnish the botanist with an introduction to the chemistry of botany, and the chemist and chemical physiologist with a knowledge of the substances of chemical interest and importance derived from plants. It is divided into ten sections dealing with the different classes of chemical compounds or agents—fats, carbohydrates, glucosides, tannins, pigments, enzymes, and so forth—met with in the vegetable kingdom. The book contains a deal of information not previously collected together, and should be of service to botanists, physiologists, and chemists alike.

Dr. CUSHMAN's *Chemistry and Civilization*⁹ consists of six discursive chapters in which the author, regarding the science from different points of view, endeavours to set out the main facts about it that should appeal to the man in the street. His treatment is largely historical, but besides delving into the past the author looks forward to the future. The book is meant for readers who know nothing of chemistry as well as for those who have a little knowledge of it, and should prove interesting to both parties.

Professor COPAUX's *Introduction to General Chemistry*,¹⁰ translated by Dr. LEFFMANN, is a short and well-written account of the subject meant for intelligent students of chemistry, and not demanding (as do so many such introductions) any great knowledge of mathematics. The metal called glaucinum by the French is properly referred to as beryllium in English, a point which may have escaped the translator.

The second and enlarged edition of Mr. KINGZETT's *Popular Chemical Dictionary*¹¹ may be recommended to the vast class of general readers who want a book in which they can look up the meaning of the chemical terms or names of chemical substances so commonly met with in everyday books and papers. We have nothing but praise for this dictionary, which fills a long-felt want and should help in stimulating the man in the street to take an interest in chemical science and technology. It is well printed, and in general remarkably accurate; the "mustard gas" mentioned on page 221 is more properly called dichloro-diethyl sulphide.

The application of the electronic theory of matter to the problems of chemical constitution made in Professor FRAY's *Electronic Conception of Valence and the Constitution of Benzene*¹² is a highly interesting study for chemists. The

author seeks to establish a new type of structural chemical formula, the "electronic formula"; he adds to the already long list a new structural formula for benzene, C_6H_6 , that goes farther in explaining graphically the chemistry of the benzene ring than any of its predecessors. The book should be read by all who are interested in the foundations of chemical science.

NOTES ON BOOKS.

The ninth edition of Professor Dr. MAX JOSEPH's well-known *Lehrbuch der Hautkrankheiten*¹³ is smaller than its predecessors. Owing to economic conditions the author states that he has been compelled to reduce its size as much as possible in order to prevent the price being so great as to make it unsaleable. As it is, the price quoted for bound copies for export is M. 130 in Germany, a considerable sum, but at the current rate of exchange a very small fraction of a pound note. Considering the size of the book (only 253 pages of text) it is remarkably complete, and the author claims that all important advances have been included in it. We do not, however, notice any mention of the work lately done on the subject of protein therapy in its possible applications to dermatological problems. This is a promising field of research, and although up to the present no startling developments have taken place, something should have been said about it. The classification adopted is mainly pathological, and is founded on a combination of those of Hebra and Auspitz; it is fairly convenient, but of course, like all other systems, is open to objection. The book is well illustrated in black and white; a large proportion of the figures are of microscopic slides and principally of pathological interest—in fact, the book is strongest on the pathological side. While acknowledging that this is a sound textbook of dermatology, although perhaps too much compressed, there is no reason to recommend it to the British student or practitioner in preference to the several excellent works lately published in his own language.

Readings in Evolution, Genetics, and Eugenics,¹⁴ compiled by Professor NEWMAN of Chicago, is a book of composite authorship in which the attempt is made to give an account of evolutionary biology in all its phases. Many of its chapters are taken from the works of other writers, Professor Newman being responsible for the next pages or chapters. It is divided into five parts, of which the first two deal with such subjects as the history and development of our views on organic evolution, and the evidences for its existence as derived from palaeontology, geographical distribution, classification, morphology, and the like. The third part discusses the causal factors of organic evolution, and is naturally mainly concerned with Darwin's work and the modifications of his views that have been approved or suggested. Part four is given to genetics, variation, biometry, and Mendel's laws of heredity; part five to eugenics and eugenics, which may be defined as the sciences of being born well and of learning to live well. The book is well arranged, and Professor Newman is to be congratulated upon the skill with which he has welded his material into a consecutive whole. It is designed for university students of biology and evolution, and has been written to fill a want said to have been long felt in America.

The official report of the Conference held last January between Commissioners of the Board of Control and medical superintendents and chairmen of mental hospitals has been published, as a pamphlet of 120 pages, by H.M. Stationery Office, at the price of 2s. 6d. The purpose of the Conference was to consider in what directions lunacy administration and the treatment of persons suffering from mental disease may be improved. The Conference was convened by Sir Frederick Willis, Chairman of the Board, and opened by Sir Alfred Mond, Minister of Health. An account of the proceedings appeared in our columns at the time.

Dr. JOHN P. TURNER has produced a rather trivial little book entitled *Ringworm and its Successful Treatment*.¹⁵ He claims to be able to cure this obstinate complaint by successive applications of tincture of iodine, oil of cade, ammoniated mercury, and resorcin, in a time varying from a fortnight to thirty weeks. X rays find no place in his system of therapy.

MEDICINAL AND DIETETIC PREPARATIONS.

Diabetic Flour for Bread-making.

We have received from Messrs. Allen and Hanbury (37, Lombard Street, London, E.C.3) a specimen of a new diabetic flour, which they have prepared in response to certain suggestions made at a discussion on the treatment of diabetes at the Medical Society of London.

In this discussion Dr. E. I. Spriggs pointed out that although the diabetic flours prepared by firms of repute were satisfactory, in that the results of analysis agreed with the manufacturers' claims, nevertheless most of these breads contained an undesirable amount of fat. He recommended a bread made from casein and white of egg, and gave directions for its preparation.

Messrs. Allen and Hanbury have prepared a flour from a mixture of casein and lactalbumin, with the addition of leavening agents—namely, cream of tartar and sodium bicarbonate. This flour, with the addition of white of egg, makes a bread essentially similar to that described by Dr. Spriggs, and the patient is saved the serious inconvenience of preparing casein from skimmed milk in his own home.

The special advantages claimed for the flour are that it contains a vanishingly small amount of carbohydrate and no fat, and that a palatable bread can easily be made from the flour. Analysis shows that the flour contained no fat and not more than 1 per cent. of carbohydrate, which latter consists only of lactose. The protein amounts to 73 per cent. of the whole flour. Two ounces of the diabetic flour mixed with the white of two eggs and baked gave a palatable loaf which possessed good keeping qualities. The preparation and cooking can be performed with ease and require no greater skill than any ordinary culinary operation. The directions on the box state that one packet is to be mixed with three eggs. This mixture gives a satisfactory product on baking, but of course the yolks of the eggs provide a considerable amount of fat. The yolk of a hen's egg contains about 5 grams (75 grains) of fat; if a fat-free bread is desired only the whites of eggs should be used.

The analysis and tests show therefore that the flour is a thoroughly satisfactory diabetic preparation; it should prove of great value to clinicians who are desirous of reducing to a minimum the fat as well as the carbohydrate in the diet of their patients.

THE PHYSIOLOGY OF LIFE ON THE ANDES.

Some account of the recent expedition to the Andes for the purpose of physiological investigation of life at high altitudes was given at a meeting of the Chelsea Clinical Society on April 11th by Mr. JOSEPH BARCROFT, F.R.S., Reader in Physiology at Cambridge University.

The expedition was arranged originally by the Royal Society, which appointed a committee to supervise it. It was supported financially by the Presbyterian Hospital, New York, Harvard Medical School, the Rockefeller Institute, the University of Toronto, the Carnegie Fund, and the Moray Fund of Edinburgh; it also received substantial subscriptions from Sir Robert Hadfield and Sir Peter Mackie. The expedition was also greatly helped by the facilities afforded by the Peruvian Corporation, Limited, and the Cerro de Pasco Copper Corporation, as well as by the Pacific Steam Navigation Company and the Grace Line.

A Mountain Laboratory.

The members of the expedition, in addition to the leader, Mr. Barcroft, were Professor J. C. Meakins of Edinburgh, Mr. Duggart of Cambridge, Dr. Redfield and Dr. Forbes of Harvard, Dr. Boek of Massachusetts General Hospital, Dr. Harrop of the Presbyterian Hospital, New York, and Dr. Binger of the Rockefeller Institute. The British contingent sailed on November 17th last to find, on arriving at Callao, the Peruvian port, that the American contingent had already been there a fortnight and had spent the time in preparing a laboratory in the shape of a luggago van 45 ft. in length, excellently adapted to this new use. The Central Railway of Peru attains a height of 15,880 ft., which is about 100 ft. higher than Mont Blanc, so that up to this altitude the party had at its disposal an excellent mobile laboratory, electric light and power, and plenty of water.

Mr. Barcroft said that the greatest advantage which the Andes presented as a field for high altitude research was the fact that there was a native population living under these alpine conditions. So far as one could judge, the race had lived here for many generations, going back to a time before the occupation not only of the Spaniards but of the Incas. These people lived at a barometric pressure of somewhere about 450 mm. of mercury, or a little over half the normal height. The town of Cerro de Pasco, which was situated at a height of 14,000 ft., was the third largest in Peru, and had been the centre of a mining industry for hundreds of years. In addition to the native population there was another population, consisting of the mining engineers and executive staff of the copper corporation, who offered themselves very willingly as subjects for experiment.

Effects of High Altitude.

The members of the expedition suffered from mountain sickness in varying degrees. None of them slept well; some had short hours of sleep, and others, while sleeping the allotted hours, had fitful and broken rest. At the end of a month all of them were mentally quite exhausted. It was clear, however, from the activities of the mining staff, that a fair amount of mental work could be sustained for long periods at 14,000 ft., but with regard to muscular work there were evident limitations to the effort even of the most acclimatized. In some respects it was surprising how much exercise could be taken. Dancing and lawn tennis were possible so long as the exercise took place on the flat, but on even the gentlest gradient the limitation which the low barometric pressure placed on the powers was obvious. The natives could perform some remarkable feats, even to carrying 100 lb. of ore on the back from a mine 250 ft. deep, but this was only done with frequent pauses, due to the necessity of squaring the oxygen account.

The facial appearance under these conditions underwent considerable change, especially in colour. Many of the natives were sallow, but those who were ruddy had cheeks, which were purplish rather than pink. One of the mining engineers had an unusually fresh complexion, but not until the party saw him at sea-level subsequently did they discover that it was pink rather than purple. The actual colour of the arterial blood bore out this observation. If taken from the radial or brachial arteries, without exposure to air, the blood appeared to be venous in character, and was, in point of fact, usually about 85 per cent. saturated with oxygen, or, as the Americans said, 15 per cent. unsaturated. The lips and nails of the visitors were obviously cyanosed on arrival, and this cyanosis, although it decreased, never entirely went away. Another interesting physical sign, which was often seen, though not present in the majority of the natives, was, and several cases were examined in was found to be unassociated with any cardiac or pulmonary lesions such as might be suspected if the appearance was met with at sea-level. The shape of the chest, as indicated by x-ray photographs, showed that the sternum was carried in an elevated position, and the ribs were more horizontal than in the case of normal people. This was true both of the American engineers and of the native population, but during the month of the party's stay none of the members acquired the habit of carrying the chest distended.

Blood Changes.

The red blood corpuscles were found to be increased in numbers, up to between 6,000,000 and 7,000,000 in members of the party, while among the residents counts up to 8,000,000 were made, with corresponding increase in the haemoglobin. There was also a marked rise in the reticulated red blood corpuscles observed among members of the party on arrival, and a corresponding fall subsequent to the descent. No nucleated red blood corpuscles were seen. The chemical changes in the blood were also of considerable interest, but in a general way they suggested that the blood acquired its oxygen more easily at high altitudes than at sea-level.

Altogether, it was clear that life could be carried on in a comparatively satisfactory manner without the production of gross permanent disabilities, consistently with the degree of unsaturation of the blood already described, for no member of the party suffered from this stay in the heights of the Andes, and Mr. Barcroft believed that there was no suffering among the mining community, at all events during the first five decades of life.

NINETIETH ANNUAL MEETING of the British Medical Association, GLASGOW, 1922.

THE ninetieth Annual Meeting of the British Medical Association will be held at Glasgow this summer, under the presidency of Sir William Macewen, LL.D., F.R.S., Professor of Surgery in the University, who will deliver his Address to the Association on the evening of Tuesday, July 25th. The sectional meetings for scientific and clinical work will be held as usual on the three following days, the mornings being given up to papers and discussions and the afternoons to clinical and laboratory demonstrations. The University Court has granted the use of the University buildings for the scientific and other purposes of the meeting. The Annual Representative Meeting will begin on the previous Friday, July 21st. The provisional programme for the scientific work of the meeting is being drawn up by the officers of the various Sections, whose names were printed in the SUPPLEMENT of February 18th, 1922, p. 39; and brief announcements of the sectional arrangements, as these are made, appear from time to time in the JOURNAL.

The last day of the meeting, Saturday, July 29th, in accordance with the custom of previous Annual Meetings, has been set apart for excursions to places of interest in Glasgow and the neighbouring West Highlands. The article published below (the fourth of the series) gives a preliminary sketch of the neighbourhood of Glasgow. Further descriptive notes will be published in subsequent issues. A note on the accommodation for visitors at Glasgow was printed in last week's SUPPLEMENT.

GLASGOW AND ITS NEIGHBOURHOOD.*

It has been said that among the great advantages enjoyed by the city of Glasgow none ranks ahead of the satisfying knowledge that immediately beyond the municipal boundaries lies a countryside of unparalleled enchantment. Sometimes it is suggested that the charm of Glasgow is that "it is so easy to get out of it," and, while that statement may seem to imply a reproach, it is in reality a compliment. Visitors to the Annual Meeting of the British Medical Association in July will, undoubtedly, be impressed by the facilities afforded for learning something of the city's environment.

Custom has decreed that every city through its local historians, its archaeologists, geologists, botanists, or guide-book chroniclers must make the most of the situation in which it is placed, and, if evidence of interesting features be not clear of itself, it must be suitably treated by skillful writers—usually enthusiasts in their subject—to make it attractive. But in Glasgow visitors readily discover that any policeman on point duty will tell them where to board a tramcar that with only one change en route runs to "the bonnie banks o' Loch Lomond," the Queen of Scottish lakes; and, while a journey by train may be quicker (and better advised), still the fact remains that the city tramlines are a link between the busy streets and the solitudes of the Highlands.

"Westward ho!" has a significance in Glasgow as a slogan for travellers. One can almost hear it sounding in the air of a summer morning when the tourists trek to the Broomielaw, where a part of the magnificent fleet of river steamers is ever lying waiting to convey all who will to the lands of desire that border the glorious Firth of Clyde. The very boardings one

passes on the way to the University proclaim, with picturesque insistence, how easy it is to reach "the laud o' Burns," the Trossachs, the castle towns of Dumbarton, Stirling, Edinburgh, the famous golf courses of Prestwick, Turnberry, and, probably most wonderful of all, the unequalled inland course at Gleneagles. Many visitors are inspired to travel by the pictorial suggestion of posters that tell now of the beauties of the Kyles of Bute on the Isle of Arran; of Rothesay (the "Madeira of Scotland"); of the green-uplands of Lanarkshire, the sylvan beauties of the Bridge of Allan and Dunblane district; of the romantic appeal of Aber-

foyle, Loch Ard, and the Lake of Menteith. Nor may one omit the attractions of Inveraray, the home of the Argylls, or the wonders of those railroad tracks—the West Highland and Callander and Oban lines—that convey one through country of magnificent beauty.

Glasgow is the centre from which in the season the tourist traffic radiates to all these points, that in the broadest sense are the city's environment, for from no centre are they more easily reached by rail, by road, or by river. The Glasgow schoolboy was not so far out when he wrote "the wonderful thing about Glasgow's environment is that it is nearer the city than the environment of any other place."

LOCH LOMOND FROM INCH TAVANAGH.

The Isle of Arran.

It were impossible within the limits of this brief article to envisage the whole, and it may be well to choose items of interest on the same principle as one might make choice from an enticing menu. The Isle of Arran has been mentioned. Geologists will find it unique. The island has gained the repute of epitomizing the geological history of both the Highlands and the Lowlands of Scotland. There are folded and contorted Highland schists, the strata of Old Red Sandstone, Carboniferous, and Triassic Ages, and indication of the Chalk of Lower Lias. Then again there are evidences

* The Glasgow and University of Glasgow, have appeared in the JOURNAL, 3rd, 1921, p. 951, January 7th.

everywhere of volcanic action, while the glacial epoch has also left its marks in perched blocks, erratic boulders, ice-worn rock surfaces, moraines, and traces of glacial lakes. Raised sea-beaches, indicating periods of land upheaval, are readily traced, and there are caves formed by the action of the sea waves in ancient cliffs now far beyond the reach of the sea. Arran is also of supreme interest to botanists, possessing as it does a rich flora and fauna. One botanist declares that in a single month (August) he noted upwards of three hundred flowering plants, including some alpine, and a profusion of mosses, ferns, liverworts, and seaweeds. The marine zoologist finds scope, too, in Arran for study in rock pools, and is well rewarded if his energies are directed to dredging off shore.

Millport Marine Biological Station.

Mention of marine zoology naturally suggests the proximity to Arran and Ayrshire of the Cumbræ and the Marine Biological Station at Millport. The romantic associations of the Burns Country and the "auld Brig o' Doon," the cottage where Burns was born, and the Memorial Gardens with their impressive monument, may appeal to many; yet, of more practical interest at the moment, the Marine Station will draw many visitors to Millport. The station owes its origin to the late Dr. Robertson, "the Cumbræ Naturalist," who died in 1897, and to the late Sir John Murray, of the famous *Challenger* expedition. Its genesis was an old canal boat used as a laboratory, and known as "The Ark." Ultimately an association was formed and the present buildings were erected from the funds. Large additions have been made to it from time to time, and its equipment has been greatly improved. It was established on its present basis in 1901, and has for its object the investigation of the marine flora and fauna of the district known as the Clyde sea area and the fostering and encouragement of biological research. The equipment includes laboratories with a very complete collection of microscopical and physiological apparatus, a museum for the preservation and exhibition of specimens, a valuable reference library, and an aquarium with a special system of tanks for research work.

Blantyre.

So far our random choice has taken us to Arran, to Ayr, and to the Cumbræ; it may now be applied to find for us other interests to intrigue the fancy or inclination of the moment we are at present anticipating. The Medical Faculty of Glasgow is proud of the memory of one of its earliest members, the late Dr. Livingstone. His birthplace, Blantyre,

is distant from the city some few miles. There he worked in a cotton-mill until ambition and zeal for foreign missionary work fire him. The strength of his Scottish character is realized in the tale told that to pursue his studies he had to walk from Blantyre daily to the old cottage in the High Street. The activities of the coal-mining industry have sullied somewhat the one-time beautiful district in which he first saw the light, but many visitors still find their way to the early home of our greatest medical missionary, and if industrialism has shorn the pilgrims' shrine of something of its early simplicity, the memory of the intrepid explorer is still cherished and adds its lustre to the village of his birth.

Birthplace of the Hunters.

In rural proximity to Glasgow, at East Kilbride, there is the birthplace of John and William Hunter. The former was surgeon to St. George's Hospital and Surgeon-Extraordinary to the King; an investigator in the sciences of anatomy, physiology, and pathology; and originator of the museum that is now the property of the Royal College of Surgeons of England. The latter, a great obstetrical surgeon also, was founder of the Hunterian Museum at Glasgow University, regarding which a special article will appear in our columns later. The Hunters were born at Long Calderwood, East Kilbride, about seven miles distant from the city. "It is not known to a tithe of the men you meet," writes one of their biographers, "that a small Scottish farmer, who more than a century ago tilled the soil within a very few miles of Glasgow, had two sons who raised themselves to the very highest position possible for men to reach in connexion with science, and the profession which they adorned; and not only so, but conferred blessings of a priceless, imperishable kind on the whole human race." To the old home of the Hunters many may wish to pay a visit, and will find that, while the surroundings may have taken on the touch of modernity, something of the old-world charm still remains.

Opportunity to say something regarding other centres of interest mentioned in the preliminary survey in this article will occur later. It may be mentioned, however, that Stirling and Dumbarton Castle can be reached by motor in an evening run. So also may Aberfoyle and the Lake of Menteith. An hour's journey by train takes one from Glasgow to Edinburgh, and in other regards the three railway companies serving Glasgow arrange their time-tables to suit connexion with the river steamers and ensure pleasant and undelayed transit to all parts of Scotland. In that, as in so many other respects, Glasgow is ideally situated for the holding of a conference.

British Medical Journal.

SATURDAY, APRIL 22ND, 1922.

PUBLIC ASYLUMS AND MENTAL HOSPITALS.

A NUMBER of recommendations in regard to the administration of asylums are made in a recent report by the Quaker Medical Society.¹ The report is perhaps all the more valuable as its writers show themselves to be deeply impressed by the difficulties inherent in the whole question, and it is written in "a Quaker spirit with a genuine desire to help." Naturally some of the suggestions are similar to those which have been made from other sources. It is recognized that certain of the present difficulties are due to the antiquated premises in which the staff of a number of asylums have to carry on their work, and it is suggested that a levelling-up process is necessary to bring these institutions into line with the more modern. Reference is made to the grouping of cases on sociological lines, and to the need of an improvement in the daily lot of those who are capable of responding to their environment. The latter aim may, it is suggested, be attained by a more varied supply of literature and games, by the organization of simple hobbies and handicrafts, and by habit training, re-education, encouragement of initiative, and a more varied dietary. A great deal is done, of course, in these directions in most asylums, and occupation-therapy forms part of the routine treatment in all these institutions. Yet it is doubtful if the possibilities of rehabilitation in the insane have hitherto been completely explored.

Much may often be done for apparently grossly deteriorated cases, but a certain attitude of pessimism is apt to arise in work which makes severe demands on doctors and nurses, and which is attended with a great deal of difficulty and discouragement. The apathy which is apt to invade these institutions is easily to be understood in view of the almost complete isolation, in some instances, from the outside world. This tendency would be largely counteracted if the public took a more intelligent and sympathetic interest in the patients in these hospitals. It is suggested in this report that regular visits from social workers to teach simple hobbies and handicrafts, as well as to help those of literary and intellectual tastes, on the lines of similar voluntary helpers' work in military hospitals during the war, would help a good deal. With this we are in entire agreement, because at present the patient who is sent to the asylum is, apart from his relatives, shunned by society, and it is seldom indeed that he is even visited by the clergyman of the parish to which he belongs. Often the lot of the patient who has recovered from an episode of insanity is one of considerable stress, and it is difficult for him to resume his place in the outside world. The public regard him with timidity, and employment is not always easy to obtain. If it were not for the existence of a Mental After-Care Association—an organization which, as we had occasion to show the other day, does much useful work for the asylum patient—there would be no alternative but the workhouse for a number of recovered cases. It is pointed out in this report that after-care welfare work amongst patients is still greatly needed, and this might be undertaken by trained psychiatric social workers, as has been done in America under the stimulating influence of the National Committee for Mental Hygiene.

¹ *The Friend*, February 17th, 1922.

A plea is made for a broader outlook in regard to mental cases on the legislative and administrative side. Reference is made to the fact that the supervision of the Board of Control is largely advisory, and that the Board has little authority over visiting committees, which may grow perfunctory in the discharge of their duties and conservative in outlook, whilst still fulfilling their legal obligations. The suggestion that visiting committees should be empowered to appoint suitable lay visitors, not necessarily from amongst their own members, to visit patients in mental hospitals frequently and freely, has much to commend it.

While we are entirely in sympathy with a more enlightened policy in regard to the treatment of mental disorder as a whole, it is well to remember that mental disease cannot always be dealt with on exactly the same lines as physical disease, since it tends to find expression in definitely abnormal conduct. Hence insanity must always of necessity involve legal and civil considerations, as well as medical. The legislative side of mental disorder is summarized in this report as follows: (1) The safeguarding of the individual against wrongful incarceration; (2) the protection of the insane patient against self-inflicted injury and ill treatment by others; (3) the protection of the public against the dangerous lunatic; (4) the defining of the civil status of the lunatic. In spite of a number of recent statements as to improper detention, we believe the mechanism at the command of the Board of Control is adequate to prevent its occurrence. Rather may there be an increasing tendency to withhold the protection of certification in certain cases where it is desirable and necessary. It must not be forgotten that, quite apart from seriously anti-social acts, the psychopathic personality is apt to exert a most unfavourable influence upon his wife and family, and his isolation may be necessary for the sake of others, just as in the case of infectious diseases. There still is such a disorder as insanity, and to give the paranoiac the label of "neurasthenia" does not render him a less dangerous element in society. A balanced attitude towards the whole question of mental disorder is particularly necessary at the present time; whatever may be done in the way of internal reform in asylums, these institutions will always be viewed by the public with a certain fear, suspicion, and dislike. Insanity will always be one of the maladies the most dreaded, and this dread will inevitably tend to express itself by some measure of antagonism to those who are responsible for the care of the insane.

MINERS' NYSTAGMUS.

THE Medical Research Council, at the request of the Home Office, appointed in 1920 a special committee to investigate the causation and means of prevention of miners' nystagmus. The members of the committee are Professor J. S. Haldane, M.D., F.R.S. (chairman), Professor E. L. Collis, M.D., T. Lister Llewellyn, M.D. (secretary), G. H. Pooley, F.R.C.S., and W. H. R. Rivers, M.D., F.R.S. The committee has issued its first report,¹ this comprises a summary of its primary conclusions, a general report on the disease by Dr. Lister Llewellyn, and a report by Dr. Rivers on psycho-neurotic symptoms associated with the disease.

Miners' nystagmus is a disease of comparatively late discovery. The earliest reference known is one by C. Turner Thackrah in a book published in London in 1832. He wrote of colliers: "Their eyes, from swelling of the lids, appear small, are affected with chronic inflammation and intolerance of full light, and many, after a few years' trial, are obliged, by the injury which their

¹ Special Report Series, No. 65, Privy Council Medical Research Council. First Report of the Miners' Nystagmus Committee. London: H.M. Stationery Office, 1922. Pp. 61. Price 1s. 6d. net.

health has sustained, and especially the weakness of their eyes, to leave the mine." Dr. Gillet of Sheffield is said to have recognized the disease in 1854. The first detailed record of a case was made by Decondé, a Belgian doctor, in 1861, in a paper dealing with nystagmus generally. In 1875 C. Bell Taylor of Nottingham published a paper on "Miners' nystagmus, a new disease," in which he held the condition to be due to the overburdening of the eye muscles and to the sustained effort to see in a deficient light. Thereafter many observations on the disease were published and a variety of conditions were assigned to its production—for instance, work in a strained position, poisoning by coal gases, and labyrinthine disturbance. Two workers—Romée of Belgium and Josiah Court of this country—have consistently maintained that deficient light was the essential factor in the production of the disease. Opinion is now generally in favour of this view, and the finding of the committee is completely in favour of it. The modern teaching is that the disease is either a general fatigue of the whole oculo-motor system or a general neurosis with special local manifestations in the oculo-motor apparatus.

The disease was added to the schedule of industrial diseases in the Workmen's Compensation Act of 1906. At first "nystagmus" was given as the specific symptom of the disease; but in 1913 a wider definition was drawn up—"the disease known as miners' nystagmus, whether occurring in miners or others, and whether the symptom of oscillation of the eyeballs be present or not." With the wider definition the number of cases receiving compensation has risen rapidly. In 1920 no fewer than 2,865 new cases were certified, making a total of 7,028, receiving compensation to the amount of £300,000 per annum on an employment roll of 978,000. It may be taken that the total incapacity rate in the United Kingdom, France, Belgium, and Germany is 0.2 per cent. of men employed underground, but the number of those who show nystagmus on examination is much higher, varying from 5 to 35 per cent. in different districts. It is calculated that the total economic loss to this country alone from this one disease is one million sterling a year.

The first and most general subjective symptom is failure of sight, which is most marked at night-time, especially in the dark winter months. The worker cannot perform the more skilled part of his work, he fails to find his tools, walking underground is difficult, the movements of his comrades' lamps annoy him, he may become irritable or quarrelsome, and his bad work may lead to further trouble. As the disease progresses sleep is broken by headaches and dreams; there is giddiness on exertion and dread of light. Later, after prolonged absence from work, well-marked neurotic and even hysterical symptoms may appear. Some men after failure are able to work at once on the surface, but most require complete rest. Total incapacity may last from one to twelve months, after which time there is ability to do almost any surface work. A few extreme cases never completely recover: these men are unable to do any colliery work again. It is observed that with the beginnings of recovery the earlier the man starts surface work the better is the prognosis. A considerable body of evidence was found indicating that the attention paid to the disease, and "compensation," have increased the frequency with which claims are made. "The increase of the number of cases of nystagmus is probably more due to the new consciousness that men were suffering from it than to any real increase." *Blantyre*. It thus: "It is quite certain in choice has taken us to not increased the prevalence of the disease; it may now be applied to. It is solely to intrigue the fancy or inclination. We are at present anticipating. The Medical and psychological Glasgow is proud of the memory of one of its increased members, the late Dr. Livingstone. His birthplace, Ben a man's

attention is called to his trouble, a mild or latent attack may be converted into the manifest variety. "It would be quite possible to 'infect' a pit, hitherto free from certified cases of nystagmus, by the introduction of a few bad cases." Stoppages of work bring out numbers of cases—men who have carried on successfully when out of work claim half-pay on their disability. Duration of compensation is to some extent influenced by methods of compensation; in one district a high incidence, low rate of return to work, and a high cost of each case, is related to a practice of lump-sum settlement: "it is quite common for men to return to work underground after such a settlement."

There is clear evidence that deficiency of light during work at the coal face is the essential cause of the disease. It is found in all classes of coal mines, and in ironstone mines where, on account of the presence of thin coal seams, safety lamps are employed. It is very uncommon in the purely naked-light mines—for example, those of Somerset and the Forest of Dean. It is common on the Continent, where safety lamps are almost universally used. It is very uncommon in America, where open lights and electric cap lamps are used. The badness of the light in the mines was demonstrated by Llewellyn in 1912; he made a large number of observations, and found that the average illumination at the coal face in safety-lamp pits was 0.018 of a foot-candle, and in candle pits 0.09. (The standard artificial lighting for schools at the child's desk is 2.5 foot-candles.) The bad light in mines is due to the feebleness of the illumination—whether lamp or electric—the rapid fouling of its protecting gauze or glass, the distance from the working point, and the high degree of absorption of light by the surrounding blackness of the coal. A lowered percentage of oxygen, the presence of moisture, and the coal dust in the air all lower the feeble light of the safety lamp. Professor Haldane examined the possibility of the disease being due to the gases abnormally present in the air of the mines. Excess of CO_2 and deficiency of oxygen could not be responsible, for these are found to a greater extent in naked-light pits, where nystagmus is practically absent. Firedamp was found experimentally to have no more physiological action than the nitrogen normally present in air. Minute traces of carbon monoxide—about 0.005 per cent.—are present, a much too low proportion to cause any appreciable physiological effects. Professor Haldane writes: "We may therefore conclude with complete certainty that the abnormal constituents in ordinary mine air have nothing to do with the production of miners' nystagmus."

The influence of alcohol was investigated and discounted. Accidents, shock, and acute illness increase liability to the disease. Hereditary predisposition, if any, is small and probably acts where there are congenital ocular defects. Errors of refraction are so common amongst the general population that their influence is difficult to determine; correction of these errors gives relief to symptoms, but may not check the oscillations. Rest from pit work and surface employment are the only known means of treatment; medicinal treatment, except that directed to the general health of the patient, is of little avail. Dark glasses delay recovery. No man loses his sight from the nystagmus, and it is the first duty of the doctor to assure his patient that the disease is curable, for nothing is so certain to re-establish the man's confidence in himself. "To tell a collier that he should never go down a pit again is almost to pass a sentence of industrial death upon him." Early employment on the surface plays as great a part in the treatment of the disease as work underground does in its production. Unfortunately, compensation arrangements check surface employment; it does not pay.

The committee unanimously agree that: (1) The essential factor in the production of miners' nystagmus

is deficient illumination, other factors have no direct influence on the disease; (2) the deficient illumination is due to the low illuminating power of the safety lamps generally used by coal miners; (3) workers at the coal face are more affected than other underground workers, and this appears to be due to the unrelieved blackness of the coal and the greater need for accurate vision; (4) distinct signs of nystagmus are present in a large proportion of coal miners, though only in a small proportion do the symptoms ever become so severe as to cause even temporary incapacity for work underground. The committee recommends that the standard of illumination should be improved to at least an equality with open-light pits, by the use of the electric cap lamp or other method which brings the light nearer the working area without shining directly into the eyes, and by an increase of whitewashing and stone dusting. It believes that by the application of these remedies miners' nystagmus of sufficient severity to cause disablement can, by degrees, be entirely prevented. Lastly, it recommends that both workman and employer be granted power to appeal to the medical referee, at intervals of not less than six months from the original certificate of disablement or date of last appeal, to assess the incapacity present. In this appeal the medical referee should certify that the man is: (1) totally incapacitated; or (2) partially incapacitated—(a) fit for surface work, (b) fit for suitable work below ground; or (3) not incapacitated.

Further investigations are in progress into the causation of the disease and into the operation underground of remedial measures, with a view to assisting the introduction and trial of new methods. This first report of the committee is sure to be received with the greatest interest by all those who have to do with the mines and the miners. It is well written, with a sufficiency of detail to establish every statement, yet it is commendably brief. The committee is to be congratulated on its work.

SCIENTIFIC SECTIONS AT THE GLASGOW ANNUAL MEETING.

The officers of the Section of Public Health at the forthcoming Annual Meeting of the British Medical Association at Glasgow are arranging an exhibition in the Kelvin Hall. This is a large hall adjacent to the University, where the sectional meetings will take place. In this hall the usual Annual Exhibition of drugs, foods, and appliances will be held, but a separate part is to be allocated for the purpose of the exhibition of the Public Health Section. A committee has been appointed in connexion with this exhibition, consisting of the medical officer of health of Glasgow, the city bacteriologist, and the medical members of Glasgow Town Council, with certain officers of the Section. The aim is to show specimens of public health interest from all the departments of Glasgow Corporation. For July 26th the following is the provisional programme of the Section: Dr. Richard J. Reece will open a discussion on "Fort sanitation in relation to the public health of the country," Dr. F. E. Fremantle, M.P., a discussion on "Public health economics," and Dr. John Brownlee a discussion on "Statistics." On July 27th Dr. Roberts will open a discussion on "Defects in children on attaining school age," and Dr. McKail a discussion on "Industrial fatigue and vocational selection on a basis of physical inquiry"; the administrative requirements for the various types of tuberculosis will also be discussed. The following provisional arrangements have been made by the Section of Neurology and Psychological Medicine. July 25th will be devoted to psychotherapy. On July 27th Sir James Purves Stewart will open a discussion on "The treatment of neurosyphilis"; and on July 28th miscellaneous papers will be communicated. The officers of the Section of Medical Sociology have chosen as the subject for discussion "Alcohol as a

beverage in its relation to certain social problems"; the problems selected are industrial efficiency, crime, mental disorders, and infantile mortality; the list of papers and openers of discussions is not yet complete. The officers of the Section of Pathology have arranged the following provisional programme. On July 26th there will be a discussion on "The origin of cancer in relation to specific forms of irritation," opened by Professor Fibiger of Copenhagen. On Thursday, July 27th, a discussion will take place on "Animal and vegetable pathology in relation to human disease," opened by Professors F. G. Halday, F.R.C.V.S., and W. H. Lang, F.R.S. The officers of the Section of Otolaryngology have arranged the following preliminary programme: A discussion on "Septic sinus thrombosis, its diagnosis and treatment," with opening papers by Sir William Milligan and Mr. Hunter Tod; a paper by Professor Holger Mygind entitled "Otogenic collateral meningitis"; and a paper by Dr. J. S. Fraser and Dr. Stephen Young entitled "Is it worth while to remove aural polypi?"

THE EPIDEMICS IN EASTERN EUROPE.

The resolutions adopted by the European Health Conference, which met in Warsaw at the close of last month, have just been issued by the League of Nations. This is a document of 16 pages, printed in French, English, and German, and it is dated Geneva, March 31st, 1922. Medical delegates attended from twenty-eight countries; the representative of Great Britain was Colonel S. P. James, M.D., of the Ministry of Health; the Italian delegates included Dr. Aldo Castellani, of the London School of Tropical Medicine. The object of the Conference was to draw up a detailed report on the epidemic situation in Eastern Europe, and submit plans for an international campaign. The Conference having heard a report by the Health Section of the League and by delegations of the different States, and having visited the quarantine stations, hospitals, and other organizations for the anti-epidemic campaign in the Russo-Polish frontier zone, recorded its unanimous opinion in a resolution of five paragraphs. The gist of these is as follows: (1) The conditions in Eastern Europe during and after the war favoured the development of dangerous epidemics, especially the insect-borne diseases typhus and relapsing fever; the food and water-borne diseases such as cholera, enteric fever, and dysentery; and other communicable diseases such as small pox. (2) The countries thus attacked did all that was possible in circumstances of great difficulty, and organized and carried out measures of control and defence; these produced a marked improvement in the first nine months of 1921. (3) Unfortunately, towards the end of the year a new and intense access of adverse conditions associated with famine, migration, and repatriation, severely overtaxed the anti-epidemic arrangements; the result was a sudden and violent recrudescence of typhus and relapsing fever, and an epidemic of cholera. The Conference is convinced that the increasing prevalence and extension of cholera in the Ukraine, together with the mass-migration towards the north-west from these and other famine-stricken areas, form an immediate danger to the rest of Europe, and the situation as a whole grows more menacing. (4) Unless much greater efforts are made without delay, the Conference believes that the present epidemiological situation will cause much more suffering and death in the infected areas, impede reconstruction, hamper trade, and threaten the whole continent of Europe. (5) The difficulties of dealing with the situation are accentuated by the lack of medical men and trained personnel, caused in part by disease and death among those who have devoted their lives to this campaign. On the motion of Dr. Castellani the Conference recommended that training courses for all grades of medical and sanitary staffs should be organized at two or three centres, with an expert international teaching staff. Further resolutions covered the following points: (1) International measures for regulating and notifying other infectious diseases besides those named in the Paris Convention; (2) mutual recognition of certificates for protective vaccination, disinfection, and delousing; (3) closer co-operation between all

States on matters of public health, based on systematic instruction and education of the people; (4) friendly mediation by the Health Section of the League of Nations when separate health conventions are drawn up between different States. Another resolution laid stress on the need for measures against famine, which is one of the chief causes of the present epidemics in Russia and the Ukraine. A concluding resolution outlined the steps to be taken to secure financial aid and co-operation by all European countries in the campaign against the epidemics in Eastern Europe, this organization to have representatives upon it of States not members of the League of Nations. The report and recommendations of the Warsaw Conference will be communicated to the Genoa Conference.

A PSYCHIATRIC MILESTONE.

THE one hundredth anniversary of the establishment of Bloomingdale Hospital as a separate department for mental diseases of the Society of the New York Hospital was celebrated on May 26th, 1921. An account of the centenary celebration has been published in a volume entitled *A Psychiatric Milestone*,¹ which is both interesting and instructive. The Bloomingdale Hospital was founded at a time when a wave of reform in the treatment of the insane was rising in Europe under the influence of Pinel in France and William and Samuel Tuke in England. Thomas Eddy, a philanthropic Quaker governor of the Society of the New York Hospital, becoming aware of this movement, was largely responsible for the creation of this institution, which has done so much for the insane in America. The history of the hospital was well worth recording, and as a number of well-known psychiatrists gave addresses at the centenary, we are presented with a valuable survey of the modern attitude towards the problems of mental disorder. Dr. W. L. Russell, medical superintendent, in describing the medical development of Bloomingdale Hospital, points out with a great deal of truth that, notwithstanding the great benefit which has been derived from physical measures in the study and treatment of mental disorders and the well-founded hopes of greater advances in this direction, the main task still continues to be what Pinel calls the management of the mind. Thus the treatment of the insane differs in some respects from that of any other form of illness; it must be humanistic and personal rather than strictly scientific. The creation of the right kind of atmosphere in an asylum is perhaps of even more importance than a research laboratory. Because this is so, as Dr. Russell says, the medical superintendent must, like Pinel, be willing to forget the empty honour of his titular distinction as a physician and do whatever may be necessary to make the institution a truly medical agency for the healing of the sick. This and other observations may be regarded as timely reminders that the executive duties of the medical superintendent should not be lightly handed over to lay control, as every administrative act must have a direct influence on the well-being and treatment—in a wide sense—of the patients in a hospital for the insane.

INTERNATIONAL EXCHANGE OF LECTURERS.

THE idea of instituting an exchange of lecturers in medicine between England and Continental countries, with which a beginning was made last year, is now being pursued further by the University of London. We have received from the academic registrar of the University information regarding lectures in medical subjects by professors from Holland and from the University of Paris to be given in London next month at the house of the Royal Society of Medicine, 1, Wimpole Street, W.1, at 5 p.m. On Wednesday, May 3rd, Dr. C. Winkler, professor of clinical psychiatry in the University of Utrecht, will give a lecture in English on "The human neo-cerebellum," in the course of which he will demonstrate a case of olivopontine cerebellar atrophy; the

chair will be taken by Sir Frederick Mott. On Monday, May 22nd, Professor F. Vidal will lecture on "Anti-anaphylaxis," with Lord Dawson of Penn in the chair; on Thursday, May 25th, Professor H. Vaquez will lecture on "Dél'erythémie (Maladie de Vaquez-Osler)," with Sir Wilmot Herringham in the chair; and on Wednesday, May 31st, Professor J. Babinski will lecture on "Des reflexes de défense," with Sir J. Purves Stewart in the chair. These three lectures will be delivered in French. Particulars of two further lectures, by Dr. Murk Jansen of Leiden on June 12th, and by Professor Hijmans Van Den Bergh of Utrecht, on June 21st, will be announced later. All these addresses, arranged under the scheme for the international exchange of lecturers in medicine, are intended for advanced students of the University of London and others interested in the subjects. Admission is free without ticket. The University is naturally anxious to obtain good audiences for these distinguished visitors from France and Holland. Brief announcements will appear from time to time in the Diary of Lectures which appears each week on the last page of the SUPPLEMENT.

"THE JOURNAL OF METABOLIC RESEARCH."

IN giving a cordial welcome to the first number of our new monthly contemporary *The Journal of Metabolic Research*,¹ we realize that the absence of a publication with such a title in America, where for years metabolic investigation has been ardently and successfully pursued, is curious. Readers have been accustomed to look to the *Journal of Biological Chemistry* and other publications for the results of American work, but that such a means of publication as this, which began its career in January, was required, appears clear from the overwhelming response to a circular letter dispatched on the question. Five answers only, some of them from the highest authorities, were adverse, on the ground that the existing journals were sufficient and that the number should not be increased, or that other journals were to be lamed which would cover this field. A larger number of correspondents endorsed the project, but excused themselves from participation for personal reasons. The response was, however, so unexpectedly hearty and strong that the plans for the appearance of the journal were carried into effect more rapidly than had originally been contemplated. The editor, Dr. Frederick M. Allen, whose name is so inseparably connected with the treatment of diabetes, is supported by fifty-four collaborators, including F. W. Peabody, L. G. Rowntree, H. S. Plummer, R. T. Woodyatt, E. V. McCollum, E. C. Kendall, J. T. Halsey, P. B. Hawk, Yandell Henderson, and Casimir Funk. The journal is published monthly by the Physiologic Institute—physiatrics meaning the cure of disease by nature, and not, as may as well at once be confessed we first fancied, a misprint for the more familiar word signifying the treatment of mental diseases. The get-up of the journal is admirable. All the seven articles in this instalment are on the pathology of diabetes, and all but two by the editor, who leads off with an interesting investigation into the hydropic degeneration of the islands of Langerhans after partial pancreatectomy. This change is proved to be a specific diabetic phenomenon produced solely by overstrain of the function of the cells by diets in excess of the weakened assimilative power. The causation of this hydropic degeneration, which may occur in prolonged hyperglycaemia, even without glycosuria, is discussed in subsequent papers. Further issues of this new journal, in which it may be anticipated that basal metabolism will receive due attention, will be awaited with interest.

SUSPENDED IMPURITY IN THE AIR.

SIR NAPIER SHAW, professor of meteorology in the Royal College of Science, communicated to a recent meeting of the Royal Society a paper by J. S. Owens, M.D., giving a preliminary account of an investigation undertaken in order

¹ *A Psychiatric Milestone, Bloomingdale Hospital Centenary, 1821-1921.* Privately printed by the Society of the New York Hospital. 19-1. (Med. 8vo. pp. 220; 6 illustrations.)

¹ *The Journal of Metabolic Research*, vol. 1, January, 1922. Edited by Frederick M. Allen. Published monthly by the Physiologic Institute, New Jersey. (Pp. 153; 22 plates. 10 dols. per year.)

to devise a simple and effective method of examining the quantity and nature of dust in the air, in industrial fumes, dust in urines, smoke fogs, and the like. Dr. Owens, whose name is well known for his inquiries into smoke abatement, has devised a new method of sampling for measurement and examination: a fine jet of air is made to strike a glass surface with high velocity, and the dust is deposited on the glass; various applications of the method have been found possible. As illustrating one application experiments were described which indicate that visibility is usually a function of the amount of suspended impurity; that suspended dust travels over great distances, records being described of dust which presumably must have come from the Continent; and that the microscopical examination of such dust records indicates certain curious differences depending upon wind direction, which at present cannot be explained.

BEIT MEMORIAL FELLOWSHIPS.

THE trustees of the Beit Memorial Fellowships for medical research have now approved certain changes in the regulations. Henceforth the election of Fellows will take place in July instead of December, and work will begin on October 1st instead of January 1st. Fellows will be classified in future into Junior, Fourth Year, and Senior Fellows. Not more than six Junior Fellowships, each of £350 a year, will be awarded annually, the usual tenure being three years. An extension of one year (Fourth Year Fellowship), at £400 per annum, may be granted on the recommendation of the Advisory Board. A limited number of Senior Fellowships at £600 per annum may be awarded, the usual tenure being three years; candidates for these must have been first elected Junior Fellows on or after January 1st, 1920. No change will be made in the emolument of any Fellowship held at the coming into force of these amended regulations on May 1st.

FELLOWSHIP OF MEDICINE.

THE following further lectures have been arranged by the Fellowship of Medicine in addition to those we announced in this column last week (p. 615) during May. On June 13th, Sir William Hale-White on "The clinical symptoms of coli infection of the urine"; on June 19th, Professor H. Maclean on "Recent work on albuminuria and glycosuria"; on July 12th, Professor A. Todd on "Surgery in rheumatoid arthritis"; and on July 19th, Mr. Victor Bonney on "Myomectomy, as opposed to hysterectomy." The lectures, which are open to members of the profession, will be delivered in the West Lecture Hall of the Royal Society of Medicine, 1, Wimpole Street, W., at 5 p.m. The syllabus of a two weeks' special course in general medicine, from May 1st to May 13th, can be obtained on application to the Secretary of the Fellowship of Medicine, as can also the syllabus of a course of six lecture-demonstrations on gastro-intestinal affections in children arranged at the Children's Clinic, Western General Dispensary, from May 15th to June 1st.

WE regret to announce the death at Ashburton, Devon, on April 19th, of Sir Alfred Pearce Gould, K.C.V.O., C.B.E., consulting surgeon to the Middlesex Hospital, at the age of 70.

THE Liverpool Medical Institution has established a lectureship to commemorate the work of the late Hugh Owen Thomas. The memorial lecture will be given in the theatre of the institution on Tuesday, April 25th, at 4.30 p.m., by Sir Robert Jones, K.B.E., C.B., who has been appointed first lecturer. Sir Robert Jones has chosen for the title of his lecture, "Hugh Owen Thomas—the man and his work." The lecture is open to all medical men and women.

THE British Chirurgical Club has recently paid a visit to Holland. The party spent two days at Amsterdam, where the clinics of Professors Noordenbos and Lanz were attended. Going thence to the Hague, the members were received by Dr. Schoemaker and spent two days in his clinic; Sunday, April 9th, was also passed at the Hague, and then followed two days at Utrecht with Professor Laméris. Much of great interest was seen at all three centres.

VENEREAL DISEASE.

A COMMITTEE OF INQUIRY.

IN a letter to the *Times* on November 22nd, 1921, Lord Dawson of Penna reiterated a suggestion he had previously made (January, 1921) that the differences of opinion in regard to the best way of handling the complex problem of venereal disease would be more easily elucidated if they were embodied in the two following propositions:

- (1) What, in the present state of knowledge, are the most efficient medical measures for preventing these diseases?
- (2) How far is it ethically justifiable to apply such measures?

Lord Dawson went on to suggest that those who had the technical knowledge should get together in conference and try to arrive at conclusions on the medical and administrative aspects of the problem uninfluenced by any ethical proposition. Until some conclusion, supported by a considerable preponderance of opinion, had been reached, it could not, he said, be reasonably expected that the Ministry of Health should do otherwise than maintain impartiality, giving a fair field and no favour to the two schools of thought and action. Then, with such conclusions before them, a wider public would have to decide whether it was ethically justifiable to found a policy upon sound opinion which could only be based upon knowledge; and the Ministry of Health might with advantage extend its encouragement to a round table conference of experts widely representative, who should consider the technical aspects of the problem.

The following correspondence has passed recently between the Minister of Health and Lord Dawson:

Ministry of Health, Whitehall, S.W.1.

January 3rd, 1922.

Dear Lord Dawson,

I have noted with interest your proposal that a committee of medical men possessing the requisite special knowledge should be constituted to inquire into certain aspects of the problem of venereal disease.

I understand that in your opinion the best hope of solving this complex problem is first to endeavour to secure an authoritative pronouncement on its medical and medico-administrative aspects, the more so as men of eminence hold divergent views upon it.

The community as a whole would then consider this medical pronouncement side by side with the weighty moral and social issues involved and through its responsible representatives determine the right policy to be pursued.

As Minister of Health I am deeply concerned with this grave problem and write to say that I will afford encouragement and support to the holding of the investigation. That you should gather together a Selection Committee to nominate the members of the Committee of Inquiry would seem to be a sound and practicable method of securing the end in view.

Yours sincerely,

ALFRED MOND.

32, Wimpole Street, W.1.

March 31st, 1922.

Dear Sir Alfred Mond,

After receiving your letter of the 3rd January I proceeded to take action and with the following result.

The Committee of Selection was constituted as follows:

Sir Clifford Allbutt	Sir Archibald Garrod
Sir Anthony Bowlby	Professor Kenwood
Lord Dawson of Penn	Sir Norman Moore
Sir Walter Fletcher	Sir John Thomson Walker.

This Committee of Selection has secured the services of a Committee of Inquiry, which I am sure you will agree is alike strong in the abilities of its members and its

widely representative character. The membership of this Committee of Inquiry is as follows:

Mr. C. J. Bond, F.R.C.S.	Professor Kenwood
Surg. Commander Reginald Bond, R.N.	Sir William Leishman
Dr. John Brownlee	Dr. F. Menzies
Professor Bulloch	Sir Frederick Mott
Dr. D. S. Davies	Dr. Sequeira
Professor Dreyer	Dr. Spilshury
Col. F. E. Fremantle, M.P.	Mr. Kenneth Walker,
Dr. Dorothy Haro	F.R.C.S.

In the opinion of the Selection Committee it is of importance that the Committee of Inquiry should be presided over by a distinguished lawyer, and they have been so fortunate as to secure the services of the Right Hon. Lord Trevethin as Chairman and Mr. T. J. Tomlin, K.C., as Vice-Chairman.

The Committee of Inquiry thus constituted has the support and confidence of both the National Council for Combating Venereal Diseases, and the Society for the Prevention of Venereal Disease.

The Committee of Selection have carefully considered the terms of reference to the Committee of Inquiry and are unanimously of opinion that the following are both succinct and comprehensive:

"To consider and report upon the best medical measures for preventing Venereal Disease in the civil community having regard to administrative practicability, including cost."

This reference has the approval of the distinguished Chairman of the Committee of Inquiry.

The Committee of Selection are confident you will share their view that it would be difficult to find a Committee of Inquiry more deserving of confidence and of the support and encouragement which as Minister of Health you have already promised to extend to its deliberations.

We are in complete agreement that after the Committee of Inquiry has reported the community as a whole will have to decide how far its recommendations can be properly made the basis of policy and action.

Yours sincerely,

DAWSON OF PENN.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Easter Recess.

ON April 12th the House of Commons adjourned until April 26th, and the Lords adjourned until May 2nd.

Pensions Administration Debate.

Mr. Charles White, on April 11th, moved in the House of Commons for a select committee of inquiry into the procedure under which pensions were being reduced. He recalled that he had been a member of a Select Committee which sat in 1919 and 1920, and he appreciated that a Departmental Committee had since sat. He expected it would be said that further review at the present time was unnecessary. Nevertheless he asked for the appointment because the estimates were being reduced by about £20,000,000, and it was believed that concerted action was being taken by medical boards and inquiry officers to reduce the amounts of pensions. He asked, without any intention of being offensive, whether any hint had been given that economy must be extended in this direction.

Mr. White submitted that pensions were being reduced after the most casual and cursory examination by medical boards, and that dependants' allowances were being lessened or ended without adequate inquiry. In theory there were safeguards, but in practice they did not sufficiently protect. Allowances were being cut off in cases in which they had been granted on account of previous ill health being aggravated by war service. He submitted that there were thousands of such cases in which the men were left as human derelicts unable to obtain employment. He believed that this occurred largely because the Pensions Committees had ceased to function.

Mr. F. Roberts seconded the motion. He sought a specific answer from Mr. Macpherson whether appeals were turned down because records were not available of a man's disability on service. In regard to the full disability grant of 40s. a week he thought that it should be made absolutely firm, and not subject to possible

reduction in 1923 as regards 20 per cent. on account of lowered cost of living. Other points which he suggested should be placed before the Committee were the pensions for widows and orphans and the qualification for entitlement. Captain Bowyer and Captain Loseby continued the discussion, the latter criticizing the Ministry for the way in which they had dealt with the questions of attributability and aggravation.

The Minister's Reply.

Mr. Macpherson, in replying, said it was evident there was suspicion that because the Estimates had been brought down by £3,000,000 below what was suggested by the Geddes Committee that there was something wrong. He had previously stated, and was glad to repeat, that whatever economies were made, they should not affect the legitimate rights of the ex-service men. He had to deal with three and a half million cases, an amount nearly equal to the population of Scotland. It would be strange if some members could not come to the House of Commons with some individual case for inquiry. The first fact which he wished to impress upon the House was that the expenditure on pensions must inevitably and necessarily be a declining quantity in the future. When he became Minister of Pensions they amounted to £123,000,000 a year; they had come down this year to £111,000,000; and next year they would be £80,000,000. A year and a half ago the Ministry was receiving as many as 500,000 new claims to pensions per week, and during the last six months they had, on the average, 1,000 claims per week.

Secondly, the diminution in the expenditure had been due to three important causes. There was the re-marriage of women and dependants; children grew beyond the pensionable age of 16 and went into employment; and there was the calamity of death. In the last year, from these three causes alone, there had been a diminution of £2,500,000 in the estimate.

The third broad reason for the diminutions had to be stated more generally. The Ministry had had during the last three years spent £45,000,000 on treatment and treatment allowances, whereas in 1919, they had spent only £1,000,000. Was not that a proof that so far from stinting the men the country was prepared to pay for their welfare? The right thing to do was to attempt by all possible means to restore these men to the social and industrial life of the community. Medical treatment had been given without stint. Every year at least 500,000 men got treatment, ranging from three or four weeks to eight or nine months, and in many cases over a year or more. On any one day no fewer than 125,000 men were receiving treatment and treatment allowances—and these were generous. In the past his Department had absorbed no fewer than one-fifth of the medical profession of the country in order to give the best possible medical treatment to these men. Having spent that enormous sum of £45,000,000 in three years, were they not expected to get any return from it? Were they not expected to find men better and pensions naturally decreasing? Considering the recuperative powers of the men, it would be severe condemnation of the Government and of the Ministry if after such an expenditure they could not show some beneficial results.

Lastly, Mr. Macpherson gave another group of reasons for the diminution. Foremost, there had been a reduction in the expenditure on administration. With the concurrence of the Departmental Committee they had reduced the membership of medical boards from three to two, and they were reducing the committees in the country from 1,200 to less than 200; they had reduced the staff employed by these people, and they had reduced the main headquarters of the Ministry by 14 per cent. There was not another Minister that could show the same record. All these items accounted for the reduction of expenditure. Mr. Roberts had suggested the time had come to get rid of irksome re-examinations by medical boards. That was exactly what they had done. Under the War Pensions Act he had established a final medical board, and he hoped that by the end of next year every pensioner in the country would be examined to see whether his disability was final or not. One of the first reforms he effected at the Ministry was to make the interval of time for calling up men one year instead of three months. In arranging that final boards should be established by the end of the year he had guarded the pension when there was any doubt as to finality. In every case he gave the man the benefit of the doubt. He had left the disability a conditional disability, so that if a man got worse in the future he would be able to go to an appeal board and get a proportionate amount. Coming to the actual reductions made, Mr. Macpherson again protested against the suggestion that the Government had influenced medical boards. The controlling power was in the hands of ex-service men. He believed he was right in saying that every doctor employed was an ex-service man, and 96.8 of the men who controlled the destinies of ex-service men were ex-service men themselves. The accusation made was absurd and base. He could support this assurance by figures. There had been a general and artificial reduction of pensions it would be reflected in the figures of assessment, but they showed exactly the contrary. Men who were awarded what was termed a "conditional" pension were normally given that pension for a year, and were then medically re-examined. As far back as the figures available went—namely, two years—he found that pensions were now decreasing less than two years ago. In 1920, taking all the results of the medical re-examination of 50,000 men for six months, the average reduction in the rate of assessment on account of the improvement of the man's health was as much as six and a half points in the pensions' scale; in other words, something like 19.5 per cent. During the last six months the average rate had been 4.3 points, or something like 13 per cent. only in the scale. It was known very well that the majority of wounds was comparatively slight. The gist of the figures amounted to this—that as between now and a year ago the proportionate cases in each grade and for each degree of pension—ranging from the seriously disabled man who was getting 80, 90, or 100 per cent. disablement,

to the minor injury which was compensated for by a weekly allowance for one, two, or three years—remained exactly the same. That was to say, 7 per cent. now were and 7 per cent. a year ago were getting pensions of 70 per cent. or over. The men who had comparatively minor degrees of disorder or injury had steadily improved in health by the medical treatment provided as well as by their natural powers of recuperation, while on the other hand those who were very severely disabled had been left to draw their pensions. He quite understood that throughout certain parts of the country there was some misgiving as to the results of the examination, but what had he done? He had established medical appeal boards, with specialists on every one of them and not a single reduction was made without a personal examination by the appeal board. Members who brought forward cases against the Ministry never referred to cases which had been admitted. These medical appeal boards had in a majority of cases granted an increase, and not a decrease of the amount of pension. He had provided that there should be a jury appointed by the Lord Chancellor, of two doctors and one ex-service man to consider any appeal which came from the award of the Medical Appeal Board as to finality.

Dealing next with the question of change of entitlement, Mr. Macpherson said the charge was that the Ministry of Pensions not only changed entitlement but cancelled the pension altogether where at some given period in a pensioner's life a pension had been awarded. No one regretted more than he did that such review should be necessary. The facts were very simple. During the last year of the war and during the first year after the armistice, when thousands of men were being demobilized, the work of dealing with claims to pensions was a business of so large a volume that it was perfectly impossible for the staff of the Ministry to deal with the men at times. They had as many as 350,000 men in the military hospitals at that time. They had discharges of 60,000 men a day. These men were coming from every corner of the globe. They had no medical certificates. They were so anxious to get out of the army that they never went to the doctor to be examined. They rushed out with no evidence that they had any sign of disability. In the course of time they came back, and with the merest *prima facie* evidence they were granted pensions. He came across so many cases at that time that it was necessary to review entitlement in those cases. He regretted to find that all over the country men were drawing pensions to which they were not entitled. Having given a few extreme cases, Mr. Macpherson asked whether he was to be expected not to examine in such matters when he found that there were cases at that time still surviving. The regiments had come from all corners of the globe, their medical certificates were with the units in Mesopotamia, Egypt, and East Africa, and it was only now that he had been able to collect with a skilled staff all these medical cards. No fewer than 3,000,000 of these cards covering half an acre in cabinets existed at the present time. The House would realize the amount of work the Ministry had had to do during the last month. The process was now nearly completed. They had reviewed only 2 per cent. of those cases. In the result where the medical boards had reviewed these cases they had in the vast majority given the benefit of the doubt, and that he believed was done in accordance with the wish of the country.

Referring to the medical appeal tribunal, Mr. Macpherson said he was hoping that a conference would take place between officials of the Ministry and the Lord Chancellor's officials, because he believed there were cases that it would be wise to reopen where fresh and undoubted evidence had been obtained by the man in support of his claim. In resisting the motion for the appointment of a Select Committee, Mr. Macpherson said that the Departmental Committee which he appointed had sat for nearly eight months, and out of their 168 recommendations he believed that 116 were in active operation. Since then under the War Pensions Act last year he had appointed an Advisory Committee, and had met representatives from that House, of the country, and the various shades of opinion amongst the ex-service men, and he intended to consult them more.

Several other members followed, but the discussion was not completed when the House adjourned.

Grants to Voluntary Hospitals.—Mr. G. Barker asked, on April 12th, with reference to the terms and conditions of grants to voluntary hospitals, if the Treasury would modify the stipulation that grants made by the Commission were to be applied wholly to maintenance and in no case to capital expenditure. He made this inquiry in the interests of hospitals in the course of erection with the desire that the authorities in financial difficulties might be able to appeal to the Commission for aid to complete the work in hand. Sir A. Mond said that the Government decided against the proposal of Lord Cave's Committee for expenditure on hospitals, on the ground not paying their way on the existing buildings, and that it was unwise to build while costs were so high. He could hold out no hope of reconsideration of this decision in the present circumstances.

London Hospital Women Students.—Sir John Norton-Griffiths asked, on April 12th, if the attention of the Minister of Health had been drawn to the report that the London Hospital authorities proposed to restrict their medical teaching to men students; whether the hospital received any assistance by way of grants from the public funds; whether such grant was made with or without conditions as to its employment; and whether, seeing that the restrictions of medical teaching to male students was neither beneficial to the public health nor in agreement with the principle of grants from public funds to quasi-organizations were made the

Ministry proposed to take any action in the matter. Sir J. Gilmour, in reply, said that the Minister's attention had been drawn to the subject. The only payments made to the London Hospital from the Ministry of Health's vote were in respect of the treatment of specific diseases. No part of the grant made by the Voluntary Hospitals Commission were applicable to the expenditure of the Medical School. He understood that in the opinion of the University Grants Committee, who made certain grants to the Medical School, the question of requiring a particular school to admit women students would arise only if facilities for University education in medicine of qualified women students were inadequate. This situation had not arisen in London University.

The Schick Test for Diphtheria.—Mr. Bromfield asked, on April 11th, whether the Minister of Health had contracted with the Wellcome Laboratories for a supply of material for the Schick test for liability to diphtheria and for a supply of toxin-antitoxin for immunizing purposes, and if so, the cost and conditions. Sir A. Mond said that no contract had been made. In the few cases in which his department had supplied the material these had been obtained from the firm in question at 12s. 6d. for fifty doses of Schick toxin and 42s. for twenty-five doses of toxin-antitoxin mixture, less the usual discount. No conditions attached to this supply.

Naval Disability Pensions.—Major Bairston, for the Minister of Pensions, stated on April 12th, in answer to Sir T. Bramston, that arrangements had been made under which the origin of the disability of naval invalids would be inquired into by a naval medical board. When a man claimed that his condition was due to service in the war his case would be considered by the Ministry of Pensions.

London Asylum Patients Discharge.—Sir Alfred Mond, on April 12th, gave an assurance that all applications for the discharge of patients from the London County Mental Hospitals were considered and dealt with at each hospital by the members of visiting subcommittees appointed by the Asylum and Mental Deficiency Committee for the management of that hospital, and by them alone.

University Education for ex-Service Men.—Mr. Fisher stated, on April 11th, in answer to Sir J. D. Rees, that the latest date prescribed for the lodging of applications under the ex-service student's scheme of university training was June 30th, 1920. Applications after that date had been exceptionally entertained where the lodging of an application was prevented by retention in the forces in a remote theatre of the war or by retention in hospitals. Otherwise fresh awards had ceased. The total number of students admitted to the benefit was 26,470. The last award was made on March 7th, 1922. The sum of six million was a provisional anticipation of the total cost when the scheme was first put forward. The excess of two million fell over the total period of operations.

Imported Milk.—Sir Alfred Mond, on inquiry by Mr. Hard, on April 11th, said that so far as he was aware the conditions of production of foreign milk imported into this country were not worse than those which existed on many British farms. The amount of fresh milk imported was insignificant, and the processes to which sterilized, dried, and condensed milks were submitted were necessarily such as to minimize the risk of danger to health. All consignments of imported milk or milk products were liable to be inspected at the port of entry and those which were found to be unfit for human consumption were condemned.

ROYAL MEDICAL BENEVOLENT FUND.

THE annual meeting of the Royal Medical Benevolent Fund was held on April 4th, when Sir CHARLES SYMONDS, Honorary Treasurer, was in the chair.

Dr. NEWTON PITT, Honorary Secretary, presented the annual report, which stated that the income in the grant department showed an increase of £500 over the previous year, and this enabled the committee to increase the amount of the grants in some of the more urgent cases. Many more really deserved an increase, but this was not possible. If each subscriber would make a point of asking one medical friend to become a contributor this would help the committee greatly. At present only 7 per cent. of the profession subscribed. The total received during the year in subscriptions and donations was £3,855, while the amount distributed to 241 cases was £3,372.

In the annuity department the income amounted to £4,122. There are 178 annuitants, fifty of which are of the value of £26 per annum, one hundred of £20 per annum, and the remainder varying amounts.

The War Emergency Fund had expended since its inception upwards of £20,000, and at the present time were educating over forty sons and daughters of medical men at public and other schools. The total amount received for this fund was £35,620.

Cordial votes of thanks were accorded to the Officers, to the Editors of the *British Medical Journal* and the *Lancet*, and the Honorary Auditors.

Sir Thomas Ballow, Bt., K.C.V.O., was re-elected President. Sir Charles J. Symonds, K.B.E., Honorary Treasurer, and Dr. Newton Pitt, O.B.E., Honorary Secretary.

England and Wales.

VOLUNTARY HOSPITALS COMMISSION.

We are informed by the Ministry of Health that the grants made by the Voluntary Hospitals Commission now amount to over £127,000. Among the more important of the recent grants are:

Triscol Royal Infirmary (for reopening closed beds)	£ 3,350
Sheffield Royal Infirmary	10,000
Sheffield Royal Hospital	7,650
Royal Albert Hospital, Devonport ...	1,000
Middlesex Hospital	5,000
West London Hospital	3,500
Prince of Wales Hospital, Tottenham ...	1,800

The majority of grants up to the present have been made to London hospitals, but this is mainly due to the fact that the figures for income and expenditure in 1921 were available earlier in the case of hospitals in London than in the provinces. Hospitals which had a deficit on the maintenance account for 1921 should, it is added, take steps to complete their accounts without delay, so that they may be in a position to apply through the local Hospital Committee for a grant.

MEDICAL REMUNERATION AT PLACES OF DETENTION.

The London County Council is reducing the remuneration of doctors employed part time at the two places of detention in London in association with reformatory and industrial schools. The present remuneration of the practitioners attached to these two places—Pentonville Road and Ponton Road—is £120 and £150 a year respectively. It is proposed now to vary the remuneration according to the number of children in the institutions, which number has a tendency to fall. The scale is to be £40 10s. a year when the total number of persons (children and staff) entitled to medical attendance is under thirty, 11s. a year for each person beyond thirty, and an additional payment of £54 in respect of every 1,000 children passing through the institutions in a year. As the children dealt with at Ponton Road are of a younger age than those at Pentonville Road, and consequently need more medical care, an extra sum of £13 10s. a year is to be granted to the medical officer at the former place. The total remuneration on the basis of last year's numbers will be approximately £132 for the officer at Pentonville Road and £102 for the officer at Ponton Road.

THE QUALITY OF GAS SUPPLIED IN LONDON.

Figures were submitted to the meeting of the London County Council on April 4th with regard to the quality of the gas supplied in London. The three gas companies which supply the greater part of London are the Gas Light and Coke Company, the South Metropolitan Gas Company, and the Commercial Gas Company, and the percentages of carbon monoxide in the gas supplied by these companies in January and February of this year were respectively 15.8, 7.6, and 12.5. The corresponding figures for 1921 were 19.7, 9.6, and 17.7. Only once during the past ten years—at the time of the coal strike of 1912—has the amount of carbon monoxide in the gas supplied by any one of these companies exceeded the 20 per cent. which was stated by Professor J. S. Haldane in his evidence recently before the Departmental Committee of the Board of Trade to be a reasonable maximum.

THE ROYAL LIVERPOOL CHILDREN'S HOSPITAL.

The annual meeting of this hospital took place on April 3rd, and the report showed a deficit of £9,000 during the year 1921. Unfortunately, the total amount of the subscriptions came to less than £1,000. The chairman, Mr. Alfred Holt, pointed out the inevitable result of such a calamitous state of the hospital's finances. If sufficient support was not forthcoming, the council would be compelled to close some of the wards. In every direction the council had been held in check by shortage of funds. The system of payment by patients had been approved and the funds collected had more than justified the council in changing the practice of the last half-century. The treasurer's statement emphasized the parlous condition of the hospital's finances, stating that there was a very considerable decrease not only in the amount of annual subscriptions but in the number of subscribers as well. A bazaar is to be held next December with the object of wiping out the present deficit, but the final solution of supporting the hospital and keeping it out of debt has still to be found.

Two new appointments to the honorary staff have been made which it was found were essential to the efficiency of the hospital: Dr. W. Johnson was appointed honorary assistant physician, and Mr. P. W. Leathart was appointed honorary surgeon to the ear, nose, and throat department.

Scotland.

THE MORISON LECTURES.

PROFESSOR ELLIOT SMITH'S Morison Lectures on the evolution of the human intellect will be given, as already announced, at the Royal College of Physicians of Edinburgh during the first week in May. The first lecture, on Monday, May 1st, will deal with man's pedigree and intellectual supremacy, and the nature of the factors that contributed to the attainment of his distinctive mental aptitudes. In the second lecture, on Wednesday, May 3rd, Professor Elliot Smith will discuss the part played by the acquisition of stereoscopic vision in stimulating the growth and elaboration of the cerebral cortex along the lines that eventually made possible the emergence of the human intellectual abilities. At the beginning of the third lecture on Friday, May 5th, the influence of the cultivation of the sense of hearing will be discussed, and the lecturer will conclude his course by considering the method of attainment of intellectual pre-eminence within the human family. The lectures, which will be given at 5 o'clock on each day, will be illustrated by lantern slides.

CHILD WELFARE INSTITUTE FOR SCOTLAND.

Reference was made in the JOURNAL of April 8th (p. 579) to an impending conference to consider the report of a provisional committee appointed in 1918 for the purpose of indicating how effect might best be given to the scheme for establishing a Child Welfare Institute for Scotland. The conference, held in Edinburgh on April 4th, under the presidency of Lord Provost Hutcheson, was reminded that the trustees of the Carnegie United Kingdom Trust had offered £40,000 for the establishment of a Scottish Institute for Child Welfare, that the offer had been gratefully accepted in 1918, that a provisional committee had been for nearly four years considering the draft constitution and endeavouring to find a site for the institute, and that the trustees were feeling some disappointment that more rapid progress had not been made. Sir Leslie Mackenzie then presented a draft constitution and scheme of organization; he showed how the buildings known as James Gillespie's School could be adapted, indicated possible sources of income, and submitted an estimate of some of the annual expenses which would be necessary. In the long discussion which followed criticism was mainly directed towards the financial proposals, many speakers holding that the present was not a suitable time to establish such an institute, which would put an extra burden on the ratepayers; several were frankly incredulous as to the estimated cost of running the institute, and Professor Munro Kerr of Glasgow said he did not believe it was possible to conduct an institute of the kind on £1,500 a year and contribute anything to science. With the exception of Professor Munro Kerr the medical representatives present took no part in the discussion, which, as has been said, dealt entirely with finance; but among themselves there was a free expression of opinion that many, if not all, the objects sought for in the Institute might be obtained by co-operation with existing medical institutions and by strengthening the resources of existing child-welfare work; the proposal to set up a special library of child-welfare literature in such a city of libraries was regarded as superfluous. In the end the Lord Provost suggested that the meeting could approve generally of the constitution, that it could be sent down to all local authorities and associations and others interested for their observations, and that these bodies should be asked whether they would support an institute founded on this constitution. This suggestion was unanimously agreed to. On the day following the meeting the *Scotsman* newspaper published a leading article entitled "The Ratepayers' Burden" in which it was maintained that whilst an institute of child welfare was an estimable object in itself, the present was distinctly not the time for further costly social developments. It was also pointed out that circumstances had greatly changed since 1918, when the offer of the Carnegie Trustees had been accepted. Since the meeting a number of letters have appeared in the newspapers, most of them emphasizing the

financial difficulties of the scheme and of the time. A writer in the *Glasgow Herald* suggests that the Carnegie Trustees should earmark the grant, without prejudice, and allow a final decision to be deferred, say, till 1925.

ACTION AGAINST THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS.

A judgement given by Lord Ashmore in an action by a dental student against the Royal Faculty of Physicians and Surgeons of Glasgow and the Incorporated Glasgow Dental Hospital contains some observations of general interest. A full report appears in the *Glasgow Herald* of April 5th. His lordship said that the question in this case, stated generally, was whether a certificate of attendance granted to the plaintiff by the dean of the Glasgow Dental Hospital was or was not binding on the defendants. The determination of this general question, however, had involved a somewhat intricate inquiry as to the genuineness or otherwise of initials of members of the staff of the Dental Hospital upon charts which purported to record the details of the plaintiff's work as a student at the hospital. He said that he ought to explain that counsel for the defendants also contended, and he thought rightly so, that the defendants in the discharge of their administrative duties towards the plaintiff, and in a question with him, were not bound to establish positively and definitely that the pencillings in question were not genuine; but that it was sufficient for them to show—as his lordship thought they had shown—that they acted as they did not capriciously, but reasonably and regularly and with all care and consideration that the circumstances called for and permitted. Lord Ashmore gave judgement for the defendants, the Royal Faculty of Physicians and Surgeons of Glasgow and the Incorporated Glasgow Dental Hospital, and found them entitled to costs.

Correspondence.

PERNICIOUS ANAEMIA.

SIR,—Dr. William Hunter, in the *JOURNAL* of March 18th, expresses his intention of giving a new name ("glossitic anaemia") to the disease long and generally known as pernicious anaemia. His reasons for the change are, briefly, two in number.

First, he claims that patients are frightened by the name "pernicious anaemia." No doubt many of them are, but not, in the majority of cases, for the reason he urges. The word "pernicious," if we look it up in the dictionary, no doubt has the meaning "deadly." But as used in general speech it has not this connotation. If we say that a man is a pernicious liar we mean that he is a specially virulent sort of liar but not that his lying causes death and destruction; if we say that to be constantly changing the names of well-known diseases is a pernicious habit we mean that it is a habit to be severely reprobated but not one with necessarily fatal consequences. But if a patient has had some friend or acquaintance who has been said to be suffering from pernicious anaemia he has probably seen him get rapidly worse and speedily die without the treatment that has been applied doing much, if anything, to delay the fatal ending, and he is naturally frightened if he is told that he has the same fell disease. To call the condition "glossitic anaemia" would only have a very temporary effect. Patients for a time would be cheered by being told that they had not pernicious anaemia but only glossitic anaemia (just as many patients in past days have been reassured that they had not a cancer but only a sarcoma), but before long they would learn that the sufferers died just as surely from glossitic anaemia as from pernicious anaemia, and the name would soon acquire the same dread significance.

Secondly, he claims that glossitis is a constant and early sign of pernicious anaemia, and consequently is of outstanding value as a distinctive feature of the disease. To this I may say that for twenty years past I have especially asked every one of many scores of cases of pernicious anaemia that I have seen about soreness of the tongue. The majority have admitted it, but quite a considerable proportion have never had any sign of it, even up to a fairly late stage of the disease. I can confidently assert that "sore tongue," though a frequent sign, is by no means a constant feature of pernicious anaemia; and, further, that even when it does occur it is not necessarily an early sign.

A recent article in the *JOURNAL* gives evidence of the confusion which is liable to arise from attempts to change the names of well-known diseases. A suggestion was made some years ago to designate pernicious anaemia by the term "Addisonian anaemia." Mr. Thomas Sinclair of Belfast, writing in the *JOURNAL* of March 11th on the surgery of the blood, says: "In pernicious anaemia the part played by surgery has hitherto been inglorious if we consider the results of splenectomy in the management of the ordinary type; while in the Addisonian variety the extirpation of the adrenals has been equally unsuccessful." It is evident that he has been misled by this "pernicious" habit of changing names into confusing the so-called Addisonian anaemia ("the Addisonian variety of pernicious anaemia"), which has nothing to do with the adrenals, with Addison's disease, which, of course, has!

The one point in which I am in hearty agreement with Dr. Hunter is in his regret that both the public and practitioners in general have come to regard pernicious anaemia as almost necessarily speedily fatal, whereas it is a disease which is, for a time at any rate, eminently amenable to treatment, in which life may often be much prolonged and which may occasionally be cured.—I am, etc.,

Manchester, April 9th.

CHARLES H. MELLAND.

SUNLIGHT AND RICKETS.

SIR,—At the conclusion of your leading article in last week's *JOURNAL* (p. 611) on sunlight and rickets it is suggested that studies similar to my own in India should be repeated in this country, paying due attention both to diet and to hygiene. Such inquiries have already been carried out in Glasgow by Dr. Leonard Findlay in 1915, and again in 1918 by Miss Ferguson, working under the direction of Dr. Findlay and Professor Noël Paton. In 1919, through my association with these investigators, I became familiar with their work, and this knowledge enabled me to appreciate the fact that, if Findlay's views were correct, rickets should be common among the better classes in Nasik, where seclusion of women and children is practised. My investigations followed closely those of the Glasgow inquiry.

In Nasik conditions for such an inquiry could hardly have been better arranged in a laboratory experiment. Here the better classes had the confinement factor present with the better diet, while the poorer classes ate the poorer diet and were not confined. It would be impossible in this country to find the causal factors so suitably arranged. Bad hygiene and poor diet are both found in the poorer classes, and neither in the well-to-do; hence the well-to-do must be left out of account altogether, and in Miss Ferguson's study of the one social class it was found that the great predisposing factor was bad hygiene and poor parental care.

To my mind, the striking point was the occurrence of rickets in the better classes in India, and probably this is the only country in the world (excepting some Mohammedan states) where such a condition of affairs exists and also where seclusion of women and children is a definite custom. It should be mentioned, however, that this system of purdah—that is, seclusion of women and children—is not a religious matter so far as Hindus are concerned. All the Hindus that I have met repudiate the suggestion that their women kept purdah, but they readily admit that they are secluded by custom.

I think the strongest evidence in favour of Findlay's view is to be found in my cases of late rickets. Sixteen out of seventeen cases were in the better classes, all were females; and the age of onset in the big majority was between 12 and 13 years. Well-to-do girls go to school and run about till the age of 12, when they go into seclusion. Within a few months of this late rickets develops. There is no change in the diet. Their brothers, who eat the same diet but who do not go into purdah, do not get the disease. Neither do poorer Hindu women, who eat a much poorer diet and who keep no purdah whatever.

Lastly, I may mention that the houses occupied by the better classes in Nasik are not stuffy in the sense that we understand the term in this country. There was an absence of moving air and the rooms were small, hot, and very dark.—I am, etc.,

Glasgow, April 17th.

H. S. HUTCHISON.

SIR,—I read with interest your article on rickets in the *JOURNAL* of April 15th (p. 611). I was reminded by it of a conversation I had a few years ago in the lion house at

the Dublin Zoo. A good many lions are bred there, and a very intelligent keeper discussed their health and upbringing. He said the chief trouble they had with them was rickets, but since they had increased the amount of fat in their diet no cases of rickets had occurred. This would tend to show that the food factor is of greater importance, as the lion house is light and airy.—I am, etc.,

Acton, W., April 16th.

W. A. RUDD, M.D.

THE HOSPITAL POLICY OF THE LABOUR PARTY.

SIR,—It seems to me that the most important recommendation of the Labour party in its statement of policy with regard to hospitals is one which you do not name specifically at the beginning of your leading article of April 8th (p. 571), although it is dealt with in the course of your argument. Recommendation 11 says: "It [the Labour movement] would make all public hospitals free and open to everyone who would be likely to derive benefit from institutional treatment." This proposition (assuming that the Labour party uses the term "public hospital" to distinguish it from the private hospital or nursing home) could only be carried out by the State, and so leads naturally to Recommendation 1 and indicates the authority which, in the opinion of the Labour party, should organize a complete hospital system.

Free hospital treatment open to everybody is by no means an impossible proposition. The State, through municipalities and other public bodies, has already taken over the provision of many necessities, such as roads, sewers, water supply, postal services, the treatment of some diseases, the prevention of others, education. There is no reason to suppose that the State provision of free hospital treatment would be any more difficult than the State provision of free education. It could hardly be more costly.

In discussing the proposition of free hospital treatment for all it would be useful to have a résumé of the arguments in favour of the retention of the voluntary system, and of the evidence in support of those arguments; and for this reason I regret that your very able leader was limited mainly to criticism of the misstatements and perversions of the Labour party's manifesto. Doubtless the arguments for the voluntary system have already been set forth by Lord Cave's Committee. But the best answer to Labour's statement is to reiterate the arguments on the other side.

I suggest that the advantages of the voluntary system are to be found under the following headings: cost, competition, humane treatment of patients, freedom of staffs from bureaucratic control, encouragement of the charitable. The matters in which the voluntary system is likely to fail unless very strenuous efforts can be made are: accommodation, distribution, co-ordination, transport. The directions in which no solution will be found, whatever the aspirations of the Labour party may be, are: the avoidance of class distinction and the abolition of hours of waiting. And it is highly unlikely that representation of public bodies or of small contributors on boards of management will lead to any benefit.

There is, perhaps, some interest in the question whether there is any difference, and if so what, in the provision by public authorities of such things as sewers, and of such advantages as education and hospitals. Is it not possible that sewers do not directly affect the individual, who is therefore indifferent to the provider, whereas with the more intimate concerns of education and health there is a tendency to feel that better value is obtained by paying for them directly rather than unwittingly by means of rates?—I am, etc.,

London, W., April 12th.

CHAS. BUTTAR.

SIR,—The leading article in the JOURNAL of April 8th (p. 571) is unjust to the leaders of progressive political thought and to those medical men and women who have spent laborious years in seeking some better way by which the people may have their ills attended.

The profession of medicine has always been held in unusual honour by all sections of progressive political thought. It has been, indeed, looked to as one of the safeguards of the personal liberty of the citizen. The doctor could be relied upon, it was thought, by virtue of his humanist calling to give a sympathetic ear to the poor and ailing as against a robust and well-to-do oppressor. Recent difficulties have not

arisen on this side, but have their origin in the conduct of the insurance system by which the Government, societies, and medical practitioners appear to come into positions of disharmony.

The tragedy of the insurance service has given birth to fresh evils. The new form of service tends to set up standards of practice in which the essentials of our art in the care of the individual are subordinated to the need of keeping pace with exacting non-medical details required by a bureaucratic control. In the impossible task of working for patient, society, and committee, complaints multiply and all four parties are at loggerheads. The public, reading of these quarrels in the press, is critical of medical affairs. Tales of the wealth of doctors, their motor cars, frequent and expensive holidays, and other forms of luxuriant living mask the fact that the great majority of medical men and women have small incomes and live as modest and strenuous a life as any section of the community. The alienation of some part of public sympathy is accompanied by the increase of eclectic practitioners, mental cults, and spiritual healing, unwelcome facts to those who believe the soundest and highest forms of healing of body and mind are and should be obtainable within the fraternity of medicine.

The ancient traditions of our profession have always had an humanitarian basis, and included the highest consideration for the individual patient. This regard for the personal freedom and welfare of the patient has been equally the chief aim with the leaders of progressive political thought. They have sought in every way to gain the whole-hearted co-operation of the profession on behalf of the health of the community. How, then, has the separation, so strongly marked in the leading article, arisen? It is partly, at least, a misconception which could be removed by amicable parley. We may remind ourselves of the results of such time-old disputes by the words of Coriolanus on meeting the tribunes of the people:

"when two authorities are up,
Neither supreme, how soon confusion
May enter 'twixt the gap of both, and take
The one by the other."

The fresh disaster which has so suddenly arisen, in so far as it results from practical administrative and financial difficulties with which the Government and the societies have to contend, is their business to solve. The profession, however, is being penalized apparently through these bodies seeking to transfer blame to the profession for their own deficiencies. They cherish the fond illusion that if they can control the doctor most of these difficulties will disappear. The doctor will be taught to manage their members, and that will save them much trouble. The system now being evolved seems to be a means to that end. It is not only foreign to the customs of the healing art, but bears little resemblance to the aims and principles expressed in the best progressive political literature. On the contrary, it is directly opposed to them. Instead of making for social freedom and the evolution of a fraternal body politic, the present trend restricts the individual, creates animosity, and makes for inefficiency.

There is no support in the best progressive opinion for the control of any section of the community by another. The trend of thought is strongly against such a development and in favour of independence of the arts and crafts. Least of all would it support any governmental, financial, or industrial sections in an attempt to control and refashion an art and craft so specialized as that of medicine.

The present issue is confused partly by the use of terms which are now beginning to pass into disuse. Such are "State service" and "nationalization," referred to in the article. These earlier names have become abused and distasteful and should be replaced by others relevant to present aims.

It is clear the profession in England will during the next generation find itself on a new road. In which direction should we tend? In a letter already far too long it is impossible to pursue such a question. What we need to remember is that the best progressive political thought, far from being inimical to medical interests, is the warmest advocate of the profession. It would not hinder or enslave but aid the evolution of medicine as a free art and craft and assist its true function of thinking out and applying the best means for the relief of ailing humanity and the advancement of the health of the community.—I am, etc.,

Forest Gate, E., April 11th.

V. J. BATESON.

THE NATURE AND SIGNIFICANCE OF HEART SYMPTOMS.

SIR,—Sir James Mackenzie's article of April 1st (p. 505) raises one very interesting question, for which I think no satisfactory solution has yet been offered. We are told that one of the characteristics of heart muscle is the latent period.

This latent period may roughly be divided into two parts. No stimulus, however strong, if applied during the first half will produce a response. In the second half a stimulus will produce a response of subnormal strength, to be followed by an interval equal to the remaining moiety of the interrupted latent period and the succeeding one, before the occurrence of another normal beat. In practice these experimental deductions are confirmed in the normal heart, subject to occasional extra-systoles of auricular origin.

There are, however, two conditions—auricular fibrillation and idio-ventricular rhythm—in which the heart muscle seems to lose this characteristic.

Sir James Mackenzie has suggested, in explanation of some other peculiarities which these conditions have in common, that there is a difference in the quality rather than in the quantity of the stimulus governing the ventricular contractions. Adam suggested some years ago that the impulse arising from the sino-auricular node governed dilatation no less than contraction, and that the first part of the latent period, during which no stimulus is effective, might be regarded as a period of active dilatation, or stretching of the cardiac muscle, such as occurs in other muscles under the influence of reciprocal evacuation.

Grouping these two suggestions some conclusions may, I think, be tentatively drawn, subject to further experimental findings:

(1) That the cardiac cycle consists not merely of an active and a passive phase, but of two phases of oppositely directed activity.

(2) That the co-ordination and timing of these two phases is under the control of the conducting system of the heart.

(3) That with the disappearance of this control sporadic impulses of a contractile or dilatatory nature arise at different points in the heart musculature, and thus lead both to defective filling of the ventricles on the one hand and inadequate contraction on the other.

Finally, it may be suggested that the latent period, or dilatatory phase, is characteristic of the conducting system; and that the difference in quality, suggested by Sir James Mackenzie, may well be the entire disappearance of active dilatation, to be replaced by passive dilatation and irregular and inco-ordinated contraction.—I am, etc.,

Dublin, April 5th.

T. W. T. DILLON.

THE RECOGNITION OF AORTIC INCOMPETENCE.

SIR,—It has long been my intention to write to the JOURNAL concerning a systolic murmur at the second right space, and my attention was recalled to the subject by Dr. Brockbank's remark that he could not "hear ear to ear" with Dr. Broomhead. This murmur is undoubtedly very common, and I could let Dr. Brockbank hear it at any time. Before the war I had made the murmur the subject of a very complete investigation and had satisfied myself that I had discovered the cause of it. I did not at that time publish the paper and it has lain ever since waiting the light of day. I may say that it was at the instigation of the late Professor Greenfield of Edinburgh University and of Dr. Alex. James of Edinburgh that I went into the subject of this—as far as I could ascertain—unrecorded murmur, and that I hope to send a communication to the JOURNAL in due course.—I am, etc.,

Perth, April 7th.

THOMAS LINDSAY, M.B., F.R.C.S.E.

VIENNA KLINIKS.

SIR,—In the Klinik Hajek I saw a course being held in English for eight people, presumably Americans and English. These courses are of an advanced kind, specially adapted to the graduate student. All the cases are carefully selected and studied beforehand, so that no time is lost. This is in contrast to the English method, whereby half the time is wasted in the routine work connected with the clinic.

At the Klinik Hajek constant use is made of the binocular glass of Wessely, whereby both eyes are used for all operations. I may add that Professor Hegener of Hamburg always uses his binocular apparatus, even for the out-patient exami-

nations. No instrument maker in London seems to know anything about such instruments.

This Klinik is a large building with many small wards. Particularly striking is the large number of cases of total extirpation of the larynx. The Klinik also possesses a large phonetic laboratory with a speech clinic, which runs morning and afternoon five days in the week. It has an excellent apparatus equipment, including a fine drum for making speech records and a laryngostroboscope. It is in charge of Dr. Hugo Stern. He states that he has treated 613 cases of laryngectomy, and has taught all but two to speak well. His method is to teach them to swallow (!) air and then speak with a new vibrating adjustment formed in the lower pharynx. The success is almost incredible. Many persons return to employments where they have to speak much and to telephone. At my visit two such cases happened to come in; they were actually able to speak clearly. The result depends on the skill of the physician in teaching the patient to swallow air; this is not the gift of everybody.

The interest of Vienna in speech work is remarkable. At another hospital there is a large speech clinic in charge of a physician. In the building of the Physiological Laboratory there is the Phonogram Archive founded by the famous Professor Sigmund Exner. A Society of Experimental Phonetics—whose members are largely medical men—holds regular meetings.

This account would not be complete without reference to the conditions of living in Vienna. Two pictures may be contrasted. Living at the finest hotel and in the most expensive style I did not succeed in spending more than 6 shillings a day, as the rate of exchange was £1 = 45,000 crowns. The other picture was a sad one. An American has arranged so that the professors of the University can obtain a lunch at a certain restaurant for 40 crowns (= 1 farthing). A hundred of the most famous men of science and learning are present every day. A train fare costs 60 crowns and they cannot afford to go home and back for lunch.—I am, etc.,

E. W. SCRIPTURE,
Medical Officer of the Speech Clinic,
West End Hospital, London.

London, E., March 29th.

REDUCTION OF MEDICAL FEES.

SIR,—I would like to assure Dr. Wilson Shaw that I had no desire to make an "April fool" of him, and that I really intended him to take me seriously. I fully sympathize with his grievances, but I am afraid most of the facts he brings to your notice are entirely beside the mark as far as the suggestion contained in my letter is concerned.

If the profession consider that their pre-war fees were not a just recompense for their services, I see no reason why the whole question of fees should not be reconsidered on its merits; but to obtain that increase under the cloak of the increased cost of living solely, as was recommended by the Council of the British Medical Association, would, in my opinion, be a lack of honour on the part of the profession. It is in honour bound to fall into line with those who, like the civil servants, have been compulsorily required to submit to a reduction of their bonuses and salaries as the cost of living has come down. How much greater prestige will the profession obtain if it does this on its own initiative than if compelled to do so through the force of public opinion!

It is chiefly those who are in touch with medico-politics who appreciate the loss of prestige the profession has undergone of late years. I fully realize that it will be a big act of self-denial on the part of each one of us, and I speak for myself if my suggestion is carried out by the Council, and consequently all the more honour to us, but I am fully convinced that we are in duty bound, as the cost of living has decreased, to make some reduction on that 50 per cent. increase, and that by doing so we shall show the public that our fight against the State for just and fair remuneration is entirely a matter of principle and not a grabbing for mere filthy lucre.—I am, etc.,

Woldingham, April 9th, 1922.

W. McD. ELLIS.

THE CONFERENCE OF STAFFS OF HOSPITALS.

SIR,—Mr. Harman is right; he made no mention of non-payment of lay boards while insisting on their voluntary uncontrolled service, and thereby demonstrated his failure to grasp essential factors. Plainly, if hereafter boards are paid, the party who pays, be it State, county council, or trade union, will eventually rule the board, and farewell then to voluntary

control. Moreover, those "volunteers" whom he mentions, once they had accepted the King's money, were liable to court martial if they disobeyed orders, and their "voluntary" enlistment was no protection to them. Mr. Harman evades my actual question, which had reference only to logic and sentiment. In December, 1920, having in the morning repudiated logic on the plea of sentiment, in the afternoon he supported the Leicester motion, which originally Legan: "That the logical position for the members . . . to take up . . . is." It was a crudely unsentimental plan based exclusively on logic. It is true that Dr. Clarke, perceiving that Mr. Harman had torpedoed his pet proposal, held hurried consultation with him, and elided the passage quoted, but this belated tactical manoeuvre in no way altered the facts, and indeed, while erasing the word "logic" from his motion, Dr. Clarke forgot to eliminate it from his speech. I described at the time my impression of that conference thus: "All the morning we did lip-service to the 'voluntary system' to preserve our dignity, and murdered it in the afternoon to line our pockets." Mr. Harman has turned a second somersault concerning the Gordon Dill scheme, which he applauded in November, 1921,¹ and now condemns. There is said to be a lucky number; is it too much to hope that he may exhibit presently a third performance, and rescue the voluntary system from inevitable ruin by execrating the Leicester motion?—I am, etc.,

Chichester, April 8th.

G. C. GARRATT.

SIR,—I thank Dr. Garratt and yourself for the courtesy of a sight of Dr. Garratt's letter of April 8th. This letter, and that of his dated March 30th (printed in your issue of April 15th), contain so many excursions that, were I to attempt to deal with them serially, I fear my labour would be in vain; for even if you were so liberal of space as to print so much, I doubt if anyone would spare the time to read it. Besides, the answers to them all—are they not written in the pages of that admirable report of the proceedings of the recent Conference which was printed in the SUPPLEMENT of April 1st?

The proper retort to Dr. Garratt's general criticism, to my thinking, is not to be found in adventures into scraggy polemics or guessings as to what may be or what may hap, but it is to be found by concentrating attention on the essential points of the Association policy. These points are summed up in paragraph 3 of the introductory section of the report (printed in the SUPPLEMENT of February 25th, 1922, p. 45):

"3. The Association recognizes a dual policy as regards the voluntary hospitals: (a) that the purely charitable side should be continued wherein the whole cost of the maintenance of indigent patients is met by the gratuitous contributions received by the hospital and on whose behalf the services of the honorary medical staffs are given gratuitously; (b) that other patients who are not indigent may be received for treatment at voluntary hospitals when adequate treatment cannot be obtained elsewhere, and that for them payment should be received by the hospital either from the patients themselves or on their behalf from the authority or body referring them to the hospital, and that on account of their treatment some method of remuneration of the honorary medical staff should be arranged."

The real question is: Are these points fair and just as between all parties concerned? I for one think that they are both fair and just, and so fair and just that we members of hospital staffs may, as reasonable men, press the acceptance of them upon those other reasonable men who manage our hospitals.—I am, etc.,

London, W.1, April 12th.

N. BISHOP HARMAN.

ANTISEPTIC COAL-TAR DYES.

SIR,—With reference to the leader in last week's issue of the JOURNAL on the antiseptic action of the coal-tar dyes, it is an interesting fact that this action has been known to the mill workers in Yorkshire for many years.

More than twenty years ago the owner of a mill in Yorkshire for manufacturing and dyeing serges showed me round his works. I noticed a mill operative who had cut his finger dip it, while still bleeding, into a vat of, as far as I can remember, indigo-blue. I asked the reason for this and was informed by the owner of the mill that it was the custom of all the operatives, when they cut themselves, to bathe the injured part in the dye, as they were convinced that this prevented sepsis and hastened healing. I regret now that I did not pursue the matter further.—I am, etc.,

Glasgow, April 16th.

DAVID MACDONALD.

¹ BRITISH MEDICAL JOURNAL, SUPPLEMENT, November 25th, 1921, p. 193.

RESUSCITATION AFTER APPARENT DEATH.

SIR,—Correspondence on resuscitation after apparent death induces me to place on record the following remarkable case in which blood-letting after apparent death saved a life. It emphasizes the importance and urgency of venesection under exceptional circumstances. And the rapidity of the procedure was an essential factor if success were to be obtained.

A. B., a diver, aged 27, was removed out of a depth of water alongside a pier. He was wearing a diving dress, and was believed to be dead. I was quickly to hand and found him in breathless asphyxia with dilated pupils and insensitive conjunctivae. No pulse could be felt nor heart sounds heard on applying my head to the bare cold chest. I adopted the practice of artificial respiration (Howard method) for at least three minutes, having previously opened a vein over the right elbow with a pocket knife from one of the assembled crowd. Friction of the extremities and warmth were being attended to. Blood oozed from the vein soon after its incision, when suddenly it spurted and there was a voluntary respiratory gasp. Artificial respiration was soon followed by natural breathing. Fifteen ounces or thereabouts of venous blood had escaped from the vein when I tied the incision with my handkerchief over a small pad.

I found the interior of the diving dress quite dry and so no water had entered his chest.

The patient remained, after his removal home, blind and semi-unconscious for forty-eight hours. Petechiae were noticed on the body; melaena followed with blood in the urine. The ophthalmoscope detected retinal haemorrhages. He was also deaf. His vision returned gradually on the fourteenth day. He had no memory of what had happened to him.

At no period did he have subcutaneous injections or saline infusion. The only course of medication was calomel and Epsom salts.

He was restored to health after six weeks of invalidism.

The history of this man is interesting, for had I not released the engorgement of his venous system, had I cut down on the cardiac region and squeezed the heart, surely I should have spoilt what spark of life was still resident in that congested organ. The subsequent record of the case proves that there was much capillary escape of blood into the body tissues, including the head and abdomen.—I am, etc.,

Bournemouth, March 20th.

JOHN F. BRISCOE.

Obituary.

ARTHUR WILLIAM BACOT, F.E.S.,

Entomologist to the Lister Institute of Preventive Medicine.

By the death of Mr. A. W. Bacot on April 12th, from typhus fever contracted in the course of experimental research into this disease in Cairo, medical entomology has suffered a grievous loss, and his death adds one more to the already long toll of victims which this disease has claimed in the attempt to solve its still mysterious etiology. The circumstances are doubly tragic in that as we write (April 18th) his colleague Dr. J. A. Arkwright, who fell sick of the same disease about April 6th, lies in a critical condition.

Bacot and Arkwright went to Cairo in January of this year, at the request of the Egyptian Government, to carry out researches into typhus fever, a disease which has long been endemic in that city. The opportunity of continuing their researches in a city where fresh material would generally be available was welcomed by both experts, and all the more so as their previous experience both with trench fever, typhus fever (in Warsaw and at home), and the *Rickettsia* problem generally had indicated what might prove to be likely lines of investigation. Laboratory accommodation was provided for them at the Hygienic Institute, of which Dr. Charles Todd is director, and there, as we know from letters dated so recently as April 3rd, both workers were mainly occupied with experiments on lice infected with typhus virus obtained from cases at the Infectious Hospital. Mr. Bacot fell ill about March 25th, and for some days the diagnosis was uncertain, the onset suggesting enterica. He was removed to the Fever Hospital at Abbasieli on March 30th, and from that date the diagnosis was not in doubt. He reached a crisis about April 8th, but lung trouble with some secondary fever intervened and death took place on April 12th. Dr. Arkwright was removed to hospital on April 7th, and his wife, who had accompanied him to Cairo, was installed to help in the nursing.

Arthur William Bacot was appointed entomologist to the Lister Institute in 1911 with a long record behind him of experience and research in insect bionomics, and from that date his energies were devoted to the medical aspect of his subject. Probably few persons in the world were so well qualified as he in insect lore, and experimental technique, to

carry out research on insect vectors in connexion with human disease. Contributions from his pen, published in these pages and elsewhere since 1911, number nearly forty; here one can pick out only the more salient features of his work. From 1911 to 1914 Bacot was chiefly occupied with research into the bionomics of fleas and their rôle in the transmission of plague from rat to man. With C. J. Martin he conducted a most fascinating experimental investigation into the minute mechanism by which the infected rat-flea succeeds in passing on the virus of plague. He showed also, among other researches on fleas, that certain bacteria taken into the alimentary canal during the larval phase might survive the metamorphosis. In July, 1914, Bacot proceeded to Sierra Leone to take part in an investigation into yellow fever, his services being placed at the disposal of the Colonial Office. His work for this Commission on the bionomics of *Stegomyia fasciata* (*Aedes calopus*) appeared in 1916.

On his return to this country in October, 1915, Bacot turned his attention to the bionomics of lice, with the special object of devising simple means of sterilizing clothing and preventing louse-borne infection, and he accepted the position of honorary adviser to the War Office on entomological questions. During the war Bacot's advice in all matters pertaining to insecticides was eagerly sought and valued. In December, 1917, Bacot and Arkwright joined the Trench Fever Committee formed by the Director-General A.M.S. for the study of trench fever, and the committee was not long in being before definite experimental evidence was obtained of the carriage of the trench fever virus by the louse. Bacot had control of the entomological side of the inquiry, was responsible for the supply of infected lice, and superintended their feeding on trench fever patients and the collection of the louse excreta for further experiment. In the course of this work Arkwright, Bacot, and Duncan described the peculiar *Rickettsia* bodies found by them in the gut lumen and excreta of infected lice. These bodies did not appear in the louse until a period of eight or twelve days had elapsed after a feed on a trench fever patient, and it was only then that such lice were found capable of again infecting men.

Parallel experiments were undertaken with typhus fever virus obtained from Ireland in 1918, and since that time Bacot's work has been concerned almost exclusively with experimental research bearing on the rôle of *Rickettsia* bodies not only in lice experimentally infected with the virus of typhus fever but also in insects other than lice, such as the bed-bug, which appears to harbour very similar parasites. In 1920 Bacot's services were lent to a Commission appointed by the League of Red Cross Societies which proceeded to Poland to investigate typhus fever. The work of this Commission, recently published in book form by Drs. Wolbach and Todd, strongly supports the claim of *Rickettsia* bodies to represent the actual virus of typhus fever; the subject, however, is still *sub judice*. While in Warsaw (1920) Bacot fell a victim to trench fever, and he communicated to the *BRITISH MEDICAL JOURNAL* (1921) an admirable account of that illness with fully documented experimental details. This is of some interest in the light of his tragic death from typhus.

The loss to science by his death at the comparatively early age of 56 deprives the Lister Institute of a most able and fruitful investigator and a personality that charmed all who had the pleasure of his friendship.

J. C. G. L.

Dr. MAJOR GREENWOOD sends the following tribute to Bacot's memory:

Bacot knew the risks he ran. In his letters to me from Poland he dwelt upon the danger of infection from the excreta of lice; he was aware that even his masterly technique was not accident proof; he knew what was the prognosis of typhus in a man of 56. He also knew that no younger man had his special powers or could take his place in the collaboration with his friend Arkwright. So he gave himself for humanity, without, I believe, even dreaming that it was a sacrifice, for the note of the man's character was a selflessness which is rarer than unselfishness. He combined a masculine scepticism in thought with a feminine tenderness in action which I suppose Plato loved in Socrates:

"But I may and must pray to the gods that my departure hence be a fortunate one: so I offer this prayer, and may it be granted." With these words he raised the cup to his lips and very cheerfully and quietly drained it. Up to that time most of us had been able to restrain our tears fairly well, but when we watched him drinking and saw that he had drunk

the poison, we could do so no longer, but in spite of myself my tears rolled down in floods, so that I wrapped my face in my cloak and wept for myself; for it was not for him that I wept, but for my own misfortune in being deprived of such a friend."

There is more than one Phaedo amongst Arthur Bacot's friends.

THE LATE PROFESSOR F. D. BOYD.

Dr. NORMAN WALKER writes: Boyd and I were at the Edinburgh Academy together, but four years' difference in age makes a big gap between schoolboys, and I only knew him then as a small boy with very red hair, a very bad stammer, and a rather hasty temper. Nature gradually altered the first, and the others were conquered by his own determination. Those who listened to his lucid and interesting clinical lectures in recent years will hardly believe that in his student days conversation with a stranger was positively painful. It was probably this failing which was responsible for the fact that he failed to obtain honours with his M.B., and he used whimsically to recall his experience of meeting in an oral an examiner who had an equally bad stammer and who thought he was impudently mimicking him. He was house-physician with Dr. Brakenridge, one of the last of the old school of Edinburgh physicians, who combined a select family practice with hospital and consulting work. When I returned to Edinburgh in 1891 I found myself within a few yards of the house where Boyd had just put up his plate, and we took up the threads of a friendship which was unbroken and unclouded for over thirty years.

I do not think he had any medical ancestry, but he had an interesting family connexion with the Royal Infirmary, for his uncle, Sir Thomas Boyd, was Lord Provost when the new infirmary was built, and contributed so much to the success of that great undertaking that the managers placed his bust *vis-à-vis* to that of Drummond, who was Lord Provost when the original Royal Infirmary was founded, at the main entrance of the institution. He had the inestimable advantage of having to struggle hard in his early days, and he owed his ultimate success to his own exertions only. The way of the Edinburgh consultant is different from that of his London colleague, and Boyd began as a general practitioner, and to a small extent as a club doctor. It was probably this experience and the knowledge therein acquired that there was some good as well as a lot of evil in contract practice which was responsible for the moderate attitude he assumed during the Insurance Act controversy in 1911. Later he secured the appointment of Certifying Factory Surgeon for Edinburgh; then that of extramural clinical tutor, the duties of which post occupied the hours from 6.30 to 8.30 on four evenings of each week throughout the session; and he was one of the physicians to the New Town Dispensary, then one of the most popular of these peculiarly Edinburgh institutions. All these appointments brought him in a little money which enabled him to keep the wolf from the door. They took up a lot of his time, but not all his time. He kept steadily in view his ambition to be a hospital and consulting physician, and every minute he could spare was spent in research work in the laboratory of the Royal College of Physicians. There, under the influence of Noël Paton, he devoted himself mainly to biochemical work and published many papers, alone or conjointly with fellow workers. For a time he lectured in the extramural school on materia medica and therapeutics, and held for the usual term the post of university examiner in these subjects. But I think he was glad when the time came when he was able to transfer his energies to the teaching of clinical medicine, for, like most Edinburgh physicians, he was devoted to teaching, and he let nothing stand in the way of his clinics. As professor of clinical medicine he was chairman of the Clinical Medicine Board, and he was responsible for the organization of the special examination in clinical methods which elicited the eucommunis of the inspector of the General Medical Council.

I think the outstanding features of his character were his determination and conscientiousness. To some people work is easy; they have no temptations not to work. It was not so with Boyd. He was a keen and excellent golfer, a keen fisherman, and a good shot. Whist and later bridge attracted him, and he was one of the liveliest at the gathering of the Octogenarian Club, of which he was secretary from its initiation. But he never let any of his diversions interfere with his work. No one could ever get Boyd to play golf with them on his dispensary afternoons, and the number of times when he did not do his out-patients at the infirmary mns;

have been very few. In all these years, living so close, we saw a great deal of each other, and many a night we sat into the small hours discussing matters grave and gay. He had a very sound judgement and a well-balanced mind. His temper flamed up against injustice and wrong-doing, but it soon subsided, and his ultimate attitude to an erring brother was rather that of sorrow than of anger. His attitude during the war was characteristic of the man, and both as a very intimate friend and as convener of the Emergency Committee I probably knew more of it than anyone. He was very busy and very useful at home, he had no burning desire for military glory, and he was just beginning to reap the harvest of all his hard work in a rapidly increasing consulting practice. Further, he had only recently been appointed principal medical officer to the Standard Life Insurance Company, and the directors were not anxious to lose even for a time his services. But after careful consideration of the pros and cons he came to the conclusion that it was his duty to go, and that for him settled the matter. First as physician to the 58th General Hospital in France, and later as consultant to the forces in Egypt and Palestine, he rendered very valuable services to the army, which were recognized by the decoration of a Companionship of the Bath. His C.M.G. had been awarded for his services in the South African war.

A few days before his death he indicated a desire that there should be no display at his funeral, and in accordance with this wish the arrangements made were of the simplest possible character. But the respect and affection in which he was held were shown by the very large assemblage of Edinburgh's leading citizens when he was laid in his last rest in the Dean Cemetery beside so many of Edinburgh's honoured dead. To Mrs. Boyd, who has borne so heroically the tragedy of his long sufferings, and to his two fatherless daughters the sympathies of their friends go out in the fullest measure.

THE LATE SIR PATRICK MANSON.

Memorial Service in St. Paul's.

A SERVICE in memory of Sir Patrick Manson, G.C.M.G., M.D., F.R.S., was held at noon in St. Paul's Cathedral on Wednesday, April 12th. The officiating clergy were the Right Rev. Bishop Montgomery, Prelate of the Order of St. Michael and St. George, the Venerable E. E. Holmes, Archdeacon of London and Canon Residentiary of St. Paul's, Canon Alexander, and the Rev. E. T. R. Johnston. The service was choral, and included the hymns "Abide with me" and "Now the labourer's task is o'er," Psalm xxxiii, and the anthem by S. S. Wesley, "Thou wilt keep him in perfect peace, whose mind is stayed on Thee." The lesson was from I. Corinthians xv, and at the end of the service Chopin's "Marche funèbre" was played. The widow, Lady Manson, and Dr. and Mrs. P. Manson-Bahr were among the chief mourners. The Secretary of State for the Colonies was represented by Lord Wodehouse, the Royal Society by Sir Ronald Ross, the Royal College of Physicians by Sir Humphry Rolleston, the Royal Society of Tropical Medicine and Hygiene by Sir James Cantlie, the Seamen's Hospital Society by Sir James Michelli, the Lister Institute by Sir Frederick Andrewes, the Royal Society of Medicine by Sir John Bland Sutton, the Medical Society of London by Mr. James Berry, the University of Cambridge by Professor G. H. F. Nuttall, the London School of Tropical Medicine by Dr. H. B. G. Newham and Professor R. T. Leiper, the London (Royal Free Hospital) School of Medicine for Women by Dr. May Thorne, St. George's Hospital Medical School by Dr. Harold Spitta, the Tropical Diseases Bureau by Dr. A. G. Bagshawe, the Wellcome Bureau of Scientific Research by Dr. Andrew Balfour, the Army Medical Service by Major-General Sir William Leishman, and the Ministry of Pensions by Colonel Sir Lisle Webb. The British Medical Association was represented by Dr. N. G. Horner, Assistant Editor of the *British Medical Journal*, and Dr. R. Scott Stevenson, Sub-editor. The large attendance also included Admiral of the Fleet Sir Henry Jackson, Sir Reginald Anstons, Sir Charles Lucas, Dr. J. Mitchell Bruce, Miss Aldrich Blake, and Dr. G. C. Low, Senior Physician to the Hospital for Tropical Diseases, Endsleigh Gardens.

At a recent meeting of the Toronto Academy of Medicine Dr. Newton A. Powell, chairman of the Hospital Supplies Committee, presented a bronze tablet to the Academy in memory of the Fellows who died on active service during the war.

The Services.

TEMPORARY NAVAL RANK.

THE Board of Admiralty have decided that medical officers who were granted temporary commissions as Surgeon Rear-Admirals and Surgeon Commanders during the war, and whose commissions did not terminate before November 11th, 1918, are entitled to retain their rank and also to wear the uniform of that rank on State and other occasions of ceremony within the British Empire. The dresses and occasions on which they are to be worn will be found on pp. 2301-2 of the *Quarterly Navy List*.

I.L.S. DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 14th, at 7.45 p.m., with Lieut.-Colonel J. Anderson, C.I.E., in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 63, Addison Road, Kensington, W.14.

DEATHS IN THE SERVICES.

Lieut.-Colonel David Stuart Erskine Bain, Madras Medical Service (retired), died at St. Heliers, Jersey, on March 31st, aged 66. He was born in Edinburgh on July 23rd, 1855, the son of Staff Surgeon David Stuart Erskine Bain, Army Medical Department; he received his medical education at Charing Cross Hospital, taking the M.R.C.S. and L.S.A. in 1876. After filling the posts of resident medical officer, Newark-on-Trent Hospital, and of medical officer of the Small-pox Hospital in the same town, he entered the I.M.S. as surgeon in 1879; he became Lieutenant-colonel on March 31st, 1899, and retired on April 5th, 1910. Most of his service was spent in civil employment in the Madras Presidency, where he was superintendent of the Madras Lunatic Asylum (1884), garrison surgeon, Bangalore (1885), civil surgeon of Nerpattam (1830), and civil surgeon of Coorg (1892). He rejoined for service in the late war from February 1st, 1915, serving in the York Place Indian Hospital at Brighton till it was closed at the end of that year.

Surgeon-Major Robert Edward Heath died at Eastbourne on January 8th, aged 83. He was born at Arklow, county Wicklow, on January 1st, 1839, and educated at Belfast and Dublin; he graduated M.D. Queen's University, Ireland, in 1859, and took the M.R.C.S. in the following year. He entered the army as assistant surgeon on October 1st, 1860, became surgeon-major in 1875, and retired on half-pay in 1877. He served in the Hazara campaign on the north-west frontier of India in 1858.

Universities and Colleges.

UNIVERSITY OF WALES.

THE Council of the University of Wales has decided to confer the honorary degree of LL.D. upon Sir A. Garrod Thomas, M.D., at the meeting of the University Court to be held at Aberystwyth next July.

UNIVERSITY OF GLASGOW.

At the graduation ceremony on April 18th the following degrees were conferred:

M.D.—J. A. Gilliland.

M.B., Ch.B.—H. M. Walker, J. T. Moffat, J. E. Jeffrey, J. M. Naïr. B.Sc. (in Public Health).—H. A. Ross. * With commendation.

The following University prizes were also distributed: An Aroott prize of £25 for examination in physiological physics, H. S. Russell. Bellouston gold medals for eminent merit in thesis for M.D., D. K. Adams, T. J. Mackie, Noah Morris. Asher Asher gold medal, special class prize, for laryngology and rhinology, R. H. Burnett.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the President and Fellows held on April 7th the following were admitted to the Licence to practise midwifery of the College: Roger Calleja, Creina Shepherd.

At the same meeting Dr. Arthur Frederick Bernard Shaw was duly elected a Fellow.

THE list of successful candidates at the examination of the London School of Tropical Medicine printed last week (p. 623) should have indicated that Dr. D. Fitzgerald Moore passed with distinction.

Medical News.

SIR THOMAS LEWIS will deliver the seventh Mellon lecture on May 8th before the Society of Experimental Biology of the School of Medicine, Pittsburgh University, U.S.A., on the subject of clinical electro-cardiography.

THE Illuminating Engineering Society will hold a joint discussion with the Sections of Surgery and Ophthalmology of the Royal Society of Medicine, on the use of light in hospitals, including the illumination of wards and operating tables, and some other special applications of light. The discussion will take place on Thursday, April 27th, at 8 p.m., at the house of the Royal Society of Arts, John Street, Adelphi, W.C.2.

DR. NORMAN MACLEOD HARRIS, who served abroad during the war with the Canadian Army Medical Corps, has been appointed chief of the division of medical research of the Canadian Dominion Department of Health.

A COURSE of fourteen lectures on psycho-neuroses will be given by Dr. Millais Calpin at the London Hospital Medical College on Tuesdays and Fridays at 5.15 p.m., commencing on May 2nd. The fee for the course will be one guinea.

At the evening meeting of the Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, W.C., on April 25th, Mr. A. C. Abraham will discuss the pharmaceutical aspects of opium, and Mr. F. Browne, secretary of the Coder sub-committee, will deal with standards for surgical dressings. The chair will be taken at 8 p.m., and medical friends of members and associates will be cordially welcomed.

At the meeting of the Glasgow Medical Lunch Club on April 13th the president of the club, Dr. Frank W. Martin, was entertained as the guest of honour on the occasion of his marriage. Dr. W. Adam Burns, who was in the chair, referred to the recent wedding, and on behalf of the members expressed their good wishes to Dr. Martin for his happiness and prosperity. Dr. David McKail presented to him, in the name of the club, a handsome silver salver, suitably inscribed.

At the annual competitions of the St. John Ambulance Association at Reading on April 8th the Mayor presented Dr. G. H. R. Holden with a silver cigar and cigarette case, in recognition of his twenty-one years' service as chairman of the Reading centre.

For the Harringay division of Tottenham Dr. A. G. Newell of Harringay was re-elected a councillor by a majority of 1,164 in a straight contest with a Labour candidate.

At the meeting of the Assurance Medical Society to be held at the house of the Medical Society of London on Wednesday, May 10th, at 5.30 p.m., papers will be read by Mr. W. McAdam Eccles on "Further experiences of war wounds in general in relation to life assurance," and by Mr. G. E. Gask, C.M.G., on "War wounds of the chest and their prognosis in relation to life assurance."

DURING the Annual Conference of the Chartered Society of Massage and Medical Gymnastics a lecture and demonstration on "Tendon transplantation" will be given at the Salford Royal Hospital, on Saturday, April 29th, at 10.30 a.m., by Mr. Robert Ollerenshaw, F.R.C.S., Honorary Surgeon in charge of the Orthopaedic Department. Medical practitioners and students are invited to attend.

A COURSE of twelve lectures on the management and feeding of infants and young children will be given to medical practitioners by Dr. Eric Pritchard, physician in charge of the Infant Welfare Department at the St. Marylebone General Dispensary, Welbeck Street, W., commencing on Monday, May 1st, at 6 p.m. The fee for the course is two guineas.

PROFESSOR MAURICE ARTHUR, the well-known physiologist of Lausanne University, proposes to give a gratuitous course to students in experimental biology from July 25th to August 12th. Inquiries should be addressed to him at the Physiological Institute, Champ de l'Air, Lausanne.

THE cases of plague in India show signs of increasing. In the week ending January 7th, 1922, there were 1,944 seizures and 1,518 deaths, in that ending February 4th 2,580 seizures and 1,975 deaths, while in the week ending March 4th there were 4,004 seizures and 3,133 deaths.

SIR F. J. WILLIS, the Chairman, and Mr. A. H. Trevor and Dr. A. Rotherham, two Commissioners of the Board of Control, have been appointed to hold a sworn inquiry into the allegations of ill treatment on the part of certain attendants at Long Grove Mental Hospital, Epsom, which were made by Mr. Cox, an ex-inspector of police, before Sir Cyril Cobb's Committee. The inquiry will be opened at Long Grove Mental Hospital on Monday, April 24th, at 11 a.m., and will be open to the public.

THE centenary of Brétouneau will be celebrated at Tours from June 24th to 26th. Pierre Brétouneau first described diphtheria and gave it its name, and also differentiated typhoid fever. A committee of patronage has been formed, consisting of Professors Acharn, Gilbert, Jeanselme, Menetrier, Hervé, and Vidal, and Drs. Villaret, Laignel-Lavastine, Apert, Tricot-Royer, and Singer. The subscription of 20 francs should be sent to Dr. Dubrenil-Chambardel, École de Médecine, Tours.

THE annual post-graduate course on oto-rhino-laryngology, held by Professor Moure at Bordeaux, will take place this year from July 24th to August 5th, immediately after the tenth International Congress on Otology at Paris.

A VIOLENT outbreak of small-pox has occurred at San Domingo, Haiti. There have been 22,000 cases with 225 deaths.

PROFESSOR J. PETRI, of Berlin, the inventor of the "Petri dish," died recently.

FESTIVITIES have been organized to take place at Pau to celebrate the second centenary of Théophile de Borden (1722-76), the founder of the Vitalistic School at Montpellier.

A BUST of Dr. José Penna, the Argentine epidemiologist, was recently unveiled in the medical department of the University of Buenos Aires.

DURING 1921 four well-known Paris dermatologists—Brocq, Darier, Queyrat, and Thibierge—had to resign their hospital appointments owing to the age limit.

IT is announced that a site in Bloomsbury, adjoining the land reserved by the Government for the new buildings of the University of London, has been acquired by the Trustees of the Rockefeller Foundation, in agreement with the Minister of Health, for the proposed School of Hygiene in London.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Artilegry*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 15, South F.
4. *Bacillus*, Dublin; telephone, 4737.
5. *Edinburgh*, Edinburgh; telephone, 4361, Central.

QUERIES AND ANSWERS.

PARKINSON'S DISEASE.

MAJOR S. S. VAZIFDAR, I.M.S. (Bombay), writes: I shall be obliged if any reader will give information on the following two points: (1) Is there any remedy to check permanently the tremors and further progress of paralysis agitans? In a patient that I have, gelsemium temporarily arrested the tremors. Parathyroid extract and electrical treatment were tried ineffectively. (2) Has thyroid grafting been done in England for arresting senescence? If so, with what effect? Has thyroid or parathyroid grafting been done in any case of Parkinson's disease? If so, with what result?

SALINE TASTE.

DR. CHARLES BEGG (Bath) writes: Can any of your readers throw light on the cause of an intense salt taste in the mouth? My patient is a lady aged 40, condition of mouth and teeth perfect, general health excellent. She consulted me only for this intense saline taste, which is increased when tea is taken but is present always in a lesser degree with all food, and worse without food. She has been taking small doses of thyroid and salol for some time, and is living chiefly on eggs, milk, toast, and butter.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

376. Clinical Examination of Pulse Irregularity.

LUNDGAARD (*Klinische Wochenschrift*, March 4th, 1922) points out that in irregularity of the pulse valuable information may be obtained from its clinical examination alone, without the use of special apparatus. When the heart is beating irregularly, as in auricular fibrillation, the pulse waves produced by the smaller beats are often too feeble to reach the radial artery at the wrist; also the feeble ventricular contractions may be too feeble to open the aortic valves. Hence the number of heart beats per minute is greater than the number of pulse beats at the wrist. The difference has been termed the "pulse deficit." This "deficit" is a useful guide in diagnosis and treatment. To estimate the pulse deficit only a stethoscope and a watch are required. Two observers estimate the deficit, the watch being placed in a position where it can be seen by both. One observer counts the heart beats, the other the radial pulse beats at the wrist, for half a minute. The difference between the number of heart beats and radial pulse beats, per minute, is recorded as the "deficit." Tables are given showing the difference between the heart beats and radial pulse beats, in eighteen cases (mostly mitral disease). These indicate that in persistent arrhythmia (or auricular fibrillation) it is not sufficient to count only the radial pulse. Arrhythmia with a marked pulse deficit is usually a persistent arrhythmia, though a pulse deficit is not pathognomonic of this form of irregularity. The author records observations showing that in persistent arrhythmia after exertion the heart beats were always markedly increased in frequency, whilst the radial pulse beats were only increased a little, and in one case diminished; the pulse deficit, however, was always markedly increased. The extent of the pulse deficit during rest and after exertion gives some indication of the functional condition of the heart. The diminution of the pulse deficit is associated with an improvement in the subjective and objective condition. Cases and tables demonstrate this conclusion. In judging of the effects of treatment, records of the radial pulse alone are of comparatively little value. Observations demonstrate that the heart beats should be counted in addition and the "deficit" estimated. In treating cases of persistent arrhythmia we should aim at abolishing the pulse deficit. The pulse deficit after rest and exertion is a guide as to drugs, duration, intensity, and effects of treatment and mode of life. The author gives tables and instructive charts showing the diminution or abolishing of the pulse deficit in cases of persistent arrhythmia, under the action of digitalis, digitalis, strophanthus, and quinidine. The treatment should be continued, if possible, until the patient is able to tolerate a certain amount of exertion without a pulse deficit occurring; but in many cases this result cannot be obtained.

377. Failure of Tartar Emetic in Hydatid Disease.

FAIRLEY (*Med. Journ. of Australia*, January 28th, 1922), from observations upon two cases of hydatid disease treated with tartar emetic intravenously, concludes that, since the drug is unable to traverse the adventitia in sufficient quantities to exert any lethal effect on the parasite, it is not an effective anthelmintic for the encysted stage of *Taenia echinococcus*. In order to be successful the drug must be able to traverse the connective tissue barrier in sufficient concentration to kill the parasite, and without causing suppuration in the cyst. In both cases the complement fixation reaction remained unmodified after a full course of treatment, 1.5 grams (25 grains) being given during the preceding month. Operation in one case revealed a living hydatid cyst of the liver containing clear fluid and degenerate endocyst and daughter cysts, and analysis of the cyst walls showed no trace of antimony though 0.15 gram (2½ grains) had been administered intravenously six hours before operation in addition to the previous total course. In the case operated upon a strong positive reaction was converted into a negative result by operative intervention.

378.

Syphilitic Dyspepsia.

PATHAULT (*Bull. de la Soc. française de Derm. et de Syph.*, No. 10, 1921) draws attention to the frequency of mild intestinal symptoms due to syphilis. Whilst gummata and syphilitic ulcerations of the stomach are relatively rare,

dyspepsia associated with hyperacidity is a common manifestation of syphilis and rapidly amenable to antisyphilitic treatment. This hyperchlorhydria may be present at any stage of syphilis, and if untreated lead to grave consequences due to the defective assimilation and weakness it causes. Therefore the possibility of such symptoms being due to syphilis should be considered early by the physician, who, in spite of the denial of any history of infection and the absence of any of the classical signs of syphilis, may be assisted in his diagnosis by an inquiry into the family history, with particular reference to those accidents imputable to syphilitic disease. The coexistence of intractable and persistent headaches is a suggestive sign, as is also the fact that the dyspeptic symptoms show no tendency to disappear in response to purely gastric treatment. In carrying out a strenuous course of antisyphilitic treatment in such cases the physician not only removes the dyspepsia but also cures the syphilis, and prevents the more serious conditions which would have followed—namely, chronic gastritis and ulceration of the stomach.

379.

Orchitis in Scarlet Fever.

MEDI (*Il Policlinico*, Sez. Prat., January 30th, 1922), who records a case of suppurative orchitis in a male child, aged 2½ years, suffering from scarlet fever, remarks that only three previous cases of genital complications of scarlet fever have been published—namely, one by Heuvel, in which inflammation of the epididymis and tunica vaginalis occurred on the nineteenth day of disease; a similar case described by Horteloup; and a third case reported by Acuña to the Paediatric Congress at Monte Video in 1918, in a child, aged 9, who developed slight bilateral orchitis, with inflammation of the epididymis on the eighth day of disease. Unlike Medi's case, none of these three cases ended in suppuration.

380.

Haemoptysis and Pulmonary Tuberculosis.

RICKMANN (*Deut. med. Woch.*, March 2nd, 1922) has made a study of the frequency of haemoptysis and the conditions under which it occurred among 1,926 patients treated at the St. Blasien Sanatorium in the period 1916-20. In 683, or 35.5 per cent., of the total there was a history of haemoptysis before admission to the sanatorium. During sanatorium treatment 151 patients, or 8 per cent., suffered from haemoptysis. The author confirms the old observation that the prognosis is exceptionally good when haemoptysis is the first sign of the disease. Even when such patients continue to bleed during sanatorium treatment their ultimate fate is better than that of patients whose first haemorrhage occurs comparatively late in the disease. Of 260 patients belonging to the former class, 60 per cent. were discharged with the disease completely latent, whereas this result was achieved only in 45.4 per cent. of all the patients who had suffered from haemoptysis. The author explains this difference by a reference to the observation that haemoptysis early in the disease often secures comparatively early diagnosis and treatment. In the period under review the frequency of haemoptysis during sanatorium treatment declined steadily year by year; in 1916, 10.5 per cent. of the residents in the sanatorium suffered from haemoptysis; by 1920 this figure had been reduced to 6.5 per cent. The author associates this decline with the adoption of x-ray treatment, which he believes does much to hasten the formation of scar tissue in the lungs. On the other hand, he has found that heliotherapy, indiscreetly pushed, is a potent factor in provoking haemoptysis.

381.

Abnormal Forms of Lichen.

PACTIER has described a chronic form of lichen with circumscribed nodules under the name of "lichen obtusus" (*Ann. de Derm. et de Syph.*, February, 1922), which he regards as distinct from other forms of lichen on both clinical and histological grounds. Clinically these horny lesions are not preceded by simple lichen, and cannot be regarded as having been derived from the papular lesions of lichen planus; they develop slowly, their evolution extending over a number of years. The chief subjective phenomenon which accompanies this disease is a severe pruritus, which, however, is not continuous but displays itself in frequent and violent attacks of itching, which is most difficult to relieve. From the histological point of view the nodule of lichen obtusus is clearly differentiated from the papule of lichen planus by the hyperkeratosis, hyperacanthosis, and sclerosis of the skin, with infiltrated areas, which characterize its pathological anatomy.

382. Etiology and Prognosis of Serous Pleurisy in Children.

NEULAND (*Klinische Wochenschrift*, March 4th, 1922) mentions the opinions of various authors who estimate that in so-called idiopathic serous pleurisy in the adult more than half of the patients, sooner or later, and mostly within the first five years, suffer from tuberculosis of the lungs. Those authors regard a serous pleurisy of the adult, which neither by the history nor by clinical examination can be attributed to any primary disease, as a tuberculous pleurisy. From his observation on 45 cases Neuland attempts to decide (1) if serous pleurisy of unknown etiology is also tuberculous in children; (2) if tuberculosis of the lungs follows a serous pleurisy in children so frequently as in adults. As regards the first question, Neuland found that 10 out of the 45 cases examined failed to give the cutaneous tuberculin reaction. He concludes that we cannot regard all cases of serous pleurisy, of unknown origin, in children as tuberculous, and that serous pleurisy in children is not so frequently tuberculous as in the adult. Moreover, whilst not denying the close relation between serous pleurisy and tuberculosis, Neuland thinks we are not justified even in concluding that all cases giving a positive cutaneous tuberculin reaction are tuberculous. As regards the second question, the subsequent development of tuberculous lung disease, he was able to obtain information in 29 cases. Of these 29 cases, 24 had given at first a positive Pirquet tuberculin reaction, 5 had been negative. At the end of periods varying from one to ten years, 23 of the 29 cases were in good health, and of these 18 had given at first a positive Pirquet reaction. Of the 6 whose health had failed 3 had suffered from pulmonary tuberculosis, 1 from tuberculous caries of the spine, and in 2 cases the condition of the lungs was indefinite, but probably tuberculous. In the 5 cases in which at first the Pirquet reaction had been negative, examination at a later period failed to reveal any signs of tuberculosis. Neuland concludes that in children the prognosis, as regards subsequent tuberculosis, is much better than in adults.

383. Calcium Lactophosphate in Cyclic Vomiting.

GREEN (*Med. Record*, January 14th, 1922) calls attention to the value of calcium lactophosphate in cyclic vomiting and severe migraine. Two cases are recorded; a boy of 7 and a girl of 8, who suffered from severe attacks of cyclic vomiting every two or three months. After a prolonged course of calcium lactophosphate, in 2-grain doses three times a day, no further attacks occurred for more than a year. In adults suffering from migraine, 5 grains three times a day taken over a considerable period have markedly relieved the symptoms, and its value is urged in those cases of periodic vomiting and severe migraine which resist all other attempts toward permanent relief.

SURGERY.**384. Fracture of Neck of Femur.**

KLEINBERG (*Med. Record*, January 7th, 1922) reports three cases of fracture of the neck of the femur in which, some months after the injury, there was non-union and persistent pain and disability, but in which the application of the Whitman abduction treatment brought about complete union and cure. One, a man aged 34, four and a half months previously, had fractured the neck of the right femur. He walked on crutches, and complained of pain in the right hip and weakness in the leg. Complete union and restoration of function were obtained by the abduction treatment in little over nine months. In the two other cases, a woman aged 65 and a man aged 69, satisfactory results followed similar treatment applied some time after the original injury, and a cure resulted in the first case by the application of treatment as late as five months after the injury. The method is not applicable to cases of non-union in which there is marked absorption of the neck and upward displacement of the shaft. These cases differed from the ordinary long-standing cases in that there was very little absorption, and the interval between the neck and the shaft was small and easily obliterated by the manipulation in applying the abduction treatment whereby contact and good alignment were obtained. Immobilization is necessary for as long a time as in the case of a recent fracture.

385. Sacralization of the Fifth Lumbar Vertebra.

MAUCLAIRE (*La Médecine*, October, 1921) states that Rossi estimates that sacralization of the fifth lumbar vertebra is responsible for 22 out of 800 cases of chronic lumbosacral pain. In 12 of Rossi's cases the lesion was bilateral and symmetrical, in 8 unilateral, and in 2 accompanied by spina

bifida occulta. Among 12 cases observed by Mauclaire sacralization was symmetrical in 7 and unilateral in 5. The disease is very rare in the child, but the lesion may be present since childhood and not become painful until adolescence or between the ages of 20 and 30. The deformity is often accompanied by other lesions of the spine, such as spina bifida or Pott's disease. Sometimes a sixth lumbar vertebra is present. The pain is situated in the angle formed by the vertebral column and posterior iliac spine, and radiates in all directions on the corresponding side and sometimes to the opposite side. The pain often passes towards the sciatic nerve, and, according to Bertolotti, cases of so-called sciatic scoliosis are almost always due to sacralization of the fifth lumbar vertebra. The onset is sometimes very sudden, as the result of a more or less intense effort or injury. If the lesion is bilateral the back is flat and normal lordosis is almost entirely absent. If the lesion is unilateral there is lumbar lordosis, the sacro-iliac region is asymmetrical, and the pelvis is inclined to the corresponding side. The pain is sometimes situated on the opposite side because there is a distension of the ligaments on that side. The condition must be distinguished from more than 20 different diseases which give rise to pain in the lumbosacral region. The prognosis is grave owing to the loss of power suffered by the patient. Treatment should first be non-operative and consist of prolonged rest, radiotherapy, and continuous currents. Operative treatment consists in resection of the enlarged transverse process of the lumbar vertebra.

386. Extreme Dilatation of the Duodenum due to Chronic Obstruction.

ROBERTS (*Arch. of Radiol. and Electrotherapy*, January, 1922) records a case of this nature discovered by radiological examination and confirmed at subsequent operation. The patient, a male aged 42 years, had suffered with attacks of abdominal pain since childhood. During the year previous to operation he had suffered from attacks of vomiting, and jaundice, and diarrhoea. X-ray examination showed that no gall stones were present. The stomach was found normal in position, size, and pyloric rhythm, and the duodenal cap was normal. Over two hours later the barium which had passed out of the stomach was seen lying in a large C-shaped sac with its lower border down in the pelvis. Above the shadow the sac was filled with fluid capped by gas. Up to forty-eight hours a small residuum of barium remained in the stomach, and the sac could be made out at repeated examinations during this time. A barium enema demonstrated the large bowel to be normal. An x-ray diagnosis of dilated duodenum was made. This was confirmed at the operation. At the duodeno-jejunal flexure a band of cicatricial tissue was found causing a partial stenosis of the gut at this point. Two inches below this was a hernial orifice in the jejunal mesentery, through which nearly all the small intestine had passed. There was no evidence of obstruction to the bowel at any point other than the above. Raymond Grégoire has reported a case of a somewhat similar nature under the name of "mega-duodenum." At the operation nothing was found to account for this dilatation.

387. Early Formation of Gall Stones in Typhoid Fever.

DUFOUR and RAVINA (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 24th, 1921) remark that, though the etiological relationship between cholelithiasis and typhoid fever is well established, the presence of calculi in the gall bladder at the end of an attack of typhoid is generally regarded as a mere coincidence, without any causal connexion between the two processes. The writers, however, have recently observed a fatal case of typhoid fever in a woman, aged 30, in whom death on the thirty-second day of disease was due to empyema, and in whose gall bladder ten calculi were found, the largest being of the size of a pea. The writers employed the method of Mignot, Gilbert, and Fournier, who had found typhoid bacilli in the centre of gall stones, and obtained a pure culture of those bacilli from the cholesterol centre of the largest of the calculi. They allude to another case observed by one of them in which, during an operation for cholecystitis in typhoid fever, the surgeon found the gall bladder filled with grit. It is thus clear that typhoid fever can give rise to a lithiasis, the elements of which may very rapidly assume a considerable size.

388. The Treatment of Scarlatinal Otitis.

SALOMONSEN (*Ugeskrift for Læger*, February 2nd, 1922) claims that the results of early radical operative treatment for scarlatinal otitis are better than those obtained by leaving otitis and mastoid disease alone until they have given rise to a superficial periantricular abscess. This latter course was recently advocated by Professor Sörensen, whose material consisted of 57 cases of periantricular phlegmon observed among about 4,000 cases of scarlatina. The author's material

covers the period May 1st, 1918, to December 31st, 1920, in which 4,447 cases of scarlatina were discharged, and 58 were operated on for scarlatinal otitis. After discharging cases which terminated fatally from such alien complications as pericarditis and diphtheria, the author finds that there was only one death from otitis after operation, and of 45 patients operated on 32 were discharged as cured, 6 with defects of the tympanum, and 6 with chronic suppuration. The author claims that giving a general anaesthetic and freely opening the diseased mastoid process at an early stage interfere less with the patient's general health than waiting till the inflammation has come to the surface, and then incising, probing, and scraping a periauricular abscess without the aid of a general anaesthetic. A periauricular abscess is, in his opinion, always the sequel to a mastoiditis which has been neglected.

289. Insufficiency of the Soft Palate.

APERT and BIGOT (*Bull. Soc. de Pédi. de Paris*, January 17th, 1922) report the case of a boy, aged 8½ years, whose pronunciation suggested that he had a cleft palate. On examination, however, no such lesion was found, but the palate was very short and the uvula very small. On the other hand, the distance between the posterior border of the soft palate and the posterior wall of the pharynx was exaggerated, suggesting that the soft palate was too small to carry out its function of obturator to the pharynx. Deglutition took place normally, but up to the age of 3 years regurgitation through the nose had been frequent. This form of malformation of the soft palate was described in 1832 by Lermoyez, who collected 12 cases, including one of his own. Since then Castex and Egger in France had published 3 cases, and Gutzmann in Germany 20 cases. In all these cases the palatal affection was usually the only malformation present. Gutzmann, however, quoted a case of Gluck's in which there was a flattening of the side of the head and thorax with a congenital cicatricial depression at the right lineal commissure. In the present case the palatal insufficiency was associated with a number of other malformations—namely, extreme brachycephaly, campylocty of the left ring finger and the second toe on both sides, absence of the xiphoid cartilage, and an undescended left testis. The intelligence was normal. The child had been born at full term and delivery had been normal. The parents were elderly, the father being 53 and the mother 42 when the child was born. The Wassermann reaction was negative. There was no similar case in the family as in some of the cases on record. Some improvement had been obtained by making the boy blow out candles, blow soap bubbles, and training him to speak correctly.

290. X-Ray Treatment of Enlarged Tonsils.

PORTMANN (*Rev. de l'ot., d'otol. et de rhinol.*, December 31st, 1921), who records an illustrative case in a girl, aged 21, states that x-ray treatment of enlarged tonsils is indicated in those cases in which the enlargement is due to lymphoid hyperplasia without an associated fibroid degeneration, a cure being obtained in such cases two to three months after the first application. The treatment is not painful, and its only drawback is that it produces a permanent epilation of the area treated below the angle of the jaw. Apart from this, the method is likely to prove valuable in cases in which for any reason surgical intervention cannot be employed.

291. The Secondary Effects and Sequels of Local Anaesthesia.

WIEDKOPF (*Deut. Zeit. f. Chir.*, December, 1921), in a review on this subject, comes to the following conclusions: (1) No secondary effects result from the use of adrenaline in the doses usually employed owing to its high dilution. (2) The secondary effects of novocain may be divided into mild effects (nausea, vomiting, palpitation, vertigo, and sweating), severe effects (collapse, excitement, and somnolence), and fatalities. (3) The secondary effects are essentially of a cerebral character, their cause being the absorption of novocain. (4) The danger of intoxication is diminished or removed by sterilization of the instruments in soda-free water, employment of thin cannulae, and careful injection without pressure. (5) The sequels of local anaesthesia consist in pain in the wound, renal irritation, and necrosis of the skin. (6) In the individual anaesthetic procedures various lesions may occur, due to the anatomical relations, such as (a) transient blindness in trigeminal anaesthesia; (b) in anaesthesia of the brachial plexus, nerve palsies, damage to lungs and pleura, pneumothorax, mediastinal emphysema, and possibly air embolism; (c) in paravertebral anaesthesia injection into the vertebral artery, transient irritation and paralysis of the vagus and sympathetic, damage to the pleura and kidneys, etc. (7) The dose of novocain may vary within wide limits; usually it should not exceed 1.25 gram. Its strength varies between 1/2 and 2 per cent. solution.

OBSTETRICS AND GYNAECOLOGY.

292. Present Tendencies in Gynaecological Treatment.

ACCORDING to GELLHORN (*Amer. Journ. of Obstet. and Gynec.*, March, 1922) there is need at the present day for a reassessment of the relative value of surgical and of non-operative treatment in gynaecology; surgical treatment, in spite of the great advances which have been produced during the last two decades, no longer deserves the pre-eminent importance which it then enjoyed. For cancer of the cervix Döderlein and also Bumm eliminate surgery altogether, and rely exclusively on radiotherapy, of which the mortality is much less than, and the percentage of cures is probably as great as, for extended hysterectomy. For fibroids x-rays and radium check the haemorrhages in about 98 per cent. and reduce the size of the tumours in about 75 per cent. of the cases, with a mortality which is negligible, as against an average mortality of 3 to 5 per cent. after surgical procedures; not all fibroids are suitable for x-ray treatment, but the overwhelming majority can be cured by non-surgical means. In chronic, and especially in gonorrhoeal pelvic inflammations the writer believes that there is a growing tendency for surgical treatment—which, to be effective, has to be radical and mutilating—to be superseded by subcutaneous injections of foreign protein or of turpentine, or by "temporary castration" by radium or x-rays, alone or in combination. Therapeutic curetting, he considers, now finds its legitimate use for abortion and polypi alone. The necessity for surgical treatment of uterine malposition will become progressively less as it is more widely recognized that 75 per cent. of all displacements occur after labour, and that these may be prevented by the proper hygiene of the puerperium or cured by the temporary use of pessaries.

293. MAYER (*Zentralbl. f. Gynäk.*, March 25th, 1922), in a discussion of the connexions at present linking gynaecology with other branches of medicine, remarks that there are signs that the "surgical era" of gynaecology, which has lasted for about thirty years, is passing. Not all the operations which had their vogue during this time (such as curetting and fixation operations on the uterus) have proved themselves justified. For cancer of the cervix and for other conditions x-ray and radium therapy are taking over some of the former functions of surgery, and gynaecology appears likely to advance along lines linking it with neurology, psychology, and endocrinology, and separating it to some extent from surgery.

294. Caesarean Section under Local Anaesthesia.

FREY-BOLLI (*Schweiz. med. Woch.*, March 23rd, 1922) has performed Caesarean section under local anaesthesia alone in 27 cases in the period 1920-21 with most satisfactory results. In 19 cases scito cervicalis and in 5 scito fundalis was performed, and in 6 cases tubal sterilization was also carried out. In one case rupture of the uterus required Porro's operation, which was also performed under local anaesthesia. The author uses a 0.5 per cent. solution of novocain suprarenin with which he successively anaesthetizes the skin, subcutaneous and subfascial tissues—including the muscles, the preperitoneal fat, and the peritoneum itself. Each dépôt contains 10 to 20 c.c.m. of this solution, and, aiming at complete anaesthesia of the deepest structures of the abdominal wall, the author does not consider the escape of a considerable quantity of the anaesthetic into the peritoneal cavity an event of any importance. He usually gives 400 to 500 c.c.m., and has, indeed, given as much as 800 c.c.m. of this solution without seeing any ill effects from it. But he is averse to injecting such a large quantity of the solution in conjunction with morphine. As a rule, the anaesthesia was complete, and only in a few cases did the patients complain of a vague sense of pressure when the infant was being removed, and the wall of the uterus was being sutured. The author insists that it is essential not to interfere with the other abdominal organs but to leave them in place; dragging on the visceral peritoneum should also be avoided. In further support of local anaesthesia, he emphasizes the risks involved in general anaesthesia both to mother and child.

295. Mental Symptoms following Artificial Menopause.

ACCORDING to LUCIO (*Ann. di Ostet. e Ginecol.*, February 23rd, 1922) the removal of both ovaries in adult women who have not attained the menopause is followed in 1 to 2 per cent. of cases only by pronounced mental disorder. The cases are related of (1) a nullipara, aged 25, in whom the operation was followed by marked psychic excitation going on to delirium and coma; and (2) a 3-para, aged 30, who, after total hysterectomy had been done with removal of the adnexa of both

sides, showed persistent pyrexia followed by a delirious and semi-conscious condition. In both patients the mental symptoms lasted into the second week, and improved rapidly on administration of ovarian extract; the second patient showed some psychopathic signs, which persisted during the ensuing four months. The author concludes that the psychosis following castration is due to the brusque interruption of ovarian function, with resulting disturbance of the thyroid, pituitary, and other allied endocrine glands; it is more likely to be conspicuous in those having a nervous constitution, hereditary or acquired, or in alcoholic subjects, but may occur independently of these factors. Pyrexia following castration, in the absence of infection, is ascribed to interference with the glands of internal secretion which regulate the oxidative processes of metabolism. Cases such as those related emphasize the importance of conserving a portion of ovarian substance or of making an autoplasmic graft whenever one of these courses is possible at radical adnexal operations.

395. X-Ray Diagnosis after Pelvic Inflation.

VAN ZWALUWENBURG, in a paper published posthumously (*Journ. of Radiology*, March, 1922), states that, apart from the demonstration of the patency of the tubes in sterility, the most valuable contribution of gaseous pelvic inflation (followed by x-ray examination) to gynaecological diagnosis consists in the exclusion of organic lesions in young subjects suffering from dysmenorrhoea and neuroses: the method is singularly successful in the detection of slight changes in the morphology and relationships of the pelvic organs, and it is fairly safe to conclude that the pelvis, which appears normal after use of the method in question, is in fact without significant pathology and does not require operative exploration. For x-ray examination of the pelvis inflated with the gas the writer suggests the name "pelycography": pelycography, he says, will usually permit the diagnosis of pregnancy after the sixth week; it may lead to the exclusion of ectopic pregnancy, but owing to the early appearance of secondary changes is of little assistance in establishing such a condition. Van Zwaluwenburg has used this method in 350 cases without untoward result. It appears that in America 3,000 to 4,000 patients have been subjected to this method of examination with five recorded fatalities, of which one was due to puncture of the spleen and another occurred in a septic case. It is said that after gaseous inflation of the peritoneal cavity distinction between renal and splenic tumours by x-ray examination is particularly facilitated.

397. Suprarenal Insufficiency in Pregnancy.

PUIG Y ROIG (*Revista Española de Obstet. y Ginecol.*, November, 1921) records the case of a multipara, aged 41, who had shown slight signs of adrenal insufficiency following her second labour, which occurred at the age of 30. During the seventh month of her last pregnancy she showed a well-marked Addisonian syndrome with intense generalized melanoderma, pigmentation of the mucous membranes, and profound asthenia. Labour was accelerated by manual dilatation of the cervix; the child was healthy. The symptoms improved with considerable rapidity during the month following labour. Adrenal insufficiency, either alone or more commonly in conjunction with insufficiency of the ovaries, liver, and thyroid, is apparently an important factor in the toxæmias of early pregnancy. A good bibliography on the subject is given by TURENNE (*Revista médica del Uruguay*, November, 1920).

398. Hyperemesis Gravidarum.

SÉDELMEIER (*Zentralbl. f. Gynäk.*, March 11th, 1922) records a case in which intractable vomiting occurred in connexion, as it was thought, with an early uterine pregnancy; after the occurrence of acute symptoms due to tubal abortion the vomiting ceased abruptly. The diagnosis was afterwards confirmed at operation. The occurrence of hyperemesis gravidarum in connexion with ectopic gestation appears to furnish evidence that this condition is a reflex of the morbid symptom after tubal rupture is quoted as evidence that the cause of pernicious vomiting is to be found in connexion with the ovum or its insertion.

PATHOLOGY.

399. Is There More Than One Kind of Rickets?

SIMPLEY, PARK, MCCOLLUM, and NINA SIMMONDS (*Amer. Journ. Dis. of Children*, February, 1922) had the above question suggested to them as the result of a series of clinical observations, and lately have endeavoured to answer it by experiments upon the rat. Two groups of rats were

used and two defective diets. The rats were given certain light rays, and both diets were with the antirachitic factor found in cod-liver oil. Their mineral content, however, differed in the following way. Group 1 diet was low in phosphorus content and high in calcium; while Group 2 had a high phosphorus content with a low calcium ratio. Both groups of rats showed all the gross changes in the skeleton associated with rickets in the human, and in Group 1 the microscopic changes were identical. In Group 2 the microscopic changes were slightly different, and many of the cases were associated with tetany. The authors found that there were two main kinds of rickets—one characterized by a normal or nearly normal blood-calcium and a low blood-phosphorus ratio; the other by a normal or nearly normal blood-phosphorus but a low calcium ratio. The first was found to be curable by light and cod-liver oil; the second by light and calcium, or cod-liver oil and calcium. For the healing of the second group calcium was essential. The relation of tetany to rickets appears to be as follows: Tetany is an expression on the part of the nervous tissues of insufficiency of the calcium ion. Rickets is an expression on the part of the skeleton of disturbed relations between the calcium and phosphorus ions. When tetany occurs with rickets it is chiefly with the low calcium form of rickets, though a few cases were found where it was associated with the low phosphorus form of rickets. It seems possible that the etiology of rickets may be varied, as other observers have found rickets associated with nephritis and developmental defects of the kidney, also in children suffering from the severer secondary anæmias. In the absence of certain light rays and an unidentified dietary factor contained in cod-liver oil any influence which would result in depression of the calcium or phosphorus ions in the blood with the formation of calcium-phosphorus ratios favourable to the development of rickets would ultimately produce the disease. There may be several such influences.

400. Bacterial Flora of Infants' Throats.

BLOOMFIELD (*Bull. Johns Hopkins Hosp.*, February, 1922) has made a study of the micro-organisms present in the throats of infants by taking swabs from the throats soon after birth and at frequent intervals subsequently. He finds that cultures made within twelve hours of birth are almost always sterile, but that organisms begin to appear soon after nursing commences, and thereafter the throats of infants support a profuse bacterial growth. But the bacterial flora is relatively simple compared with that of adults, consisting of (1) a group of organisms of the *Streptococcus* group introduced during the process of delivery from the mother; (2) non-haemolytic streptococci, which begin to appear within twenty-four hours and are present in great numbers—it is presumed that these are derived from the throats of attendants; (3) very occasionally a few diphtheroids and Gram-negative cocci are recovered. The author points out that the bacterial flora of infants differs markedly from that of adults, from whose throats non-haemolytic streptococci, Gram-negative cocci, and diphtheroids are constantly recovered, whilst influenza bacilli, pneumococci, and haemolytic streptococci are relatively frequent in adults. The latter were never found in the throats of infants. Special conditions may be necessary for the colonization of these more pathogenic organisms, whereas the simple, non-haemolytic streptococcus seems to have adapted itself completely to growth on the mucous membrane of the upper respiratory passages.

401. Etiological Importance of Pfeiffer's Bacillus in Influenza.

SINCE the etiology of influenza still remains unsettled, all careful bacteriological examinations of this disease are likely to be of value in leading to a determination of the importance of the various factors suggested. Guided by this principle, KRISTENSEN (*C. R. Soc. Biologie*, February 25th, 1922) investigated an epidemic of influenza which broke out in Denmark in January, 1922. The garrison at Copenhagen was attacked. Thirty-eight soldiers suffering from an uncomplicated form of the disease were examined, a swab from the nasopharynx being plated direct on to Fildes's medium—agar to which 5 per cent. of blood previously submitted to peptic digestion is added. Of the cases examined 63 per cent. showed Pfeiffer's bacillus on culture, as opposed to a series of 33 controls which showed a positive percentage of 15. The controls, however, contained no fewer than three persons who had recently passed through an attack of influenza. Considering the simple nature of the examination these results agree well with those obtained by a large number of workers in other countries, and go towards supporting the growing conviction of the etiological importance of Pfeiffer's bacillus.

PIONEERS AND EMPIRE BUILDERS: No. 176
FIFTH PERIOD—circa 6000 to 2000 B.C.

TRADE
MARK

'INFUNDIN' BRAND

PITUITARY (INFUNDIBULAR) EXTRACT

Indicated in cases of surgical shock, collapse, post-influenzal cardiac debility, etc.

'INFUNDIN' exercises a marked rise in blood-pressure, resulting in a slow and strengthened heart-beat.

'HYPOLOID' 'INFUNDIN' presents, in hermetically-sealed containers, a sterile, stable extract of the posterior lobe of the pituitary free from preservative. It has been known to retain its potency for over six years.

Supplied in hermetically-sealed containers of
0.5 c.c. and 1 c.c., in boxes of six

BUILDING OF THE EARLIEST FORM OF BOAT USED BY THE EGYPTIANS.—The pioneer boat-builders on the Nile began in times before history, to make

little barques of papyrus reed, and so useful did they prove that the type has never died out—the Greeks of a later age greatly admired them and they are still used in the Sudan. The little craft had no deck, but consisted simply of bundles of reeds bound together; it was broader in the middle than at the ends, and the back rose much higher from the water than the front. The smaller boats would barely hold two people, while the larger ones would carry an ox. The reeds were bound together by 3-fold ropes at intervals of about nine inches. At the left of the scene above men are

bringing bundles of papyrus, in front of them workmen are binding the bundles and shaping a boat. Below is figured a little sculptured scene called "Twisting the ropes of boat-building"; a man calls to a boy "O strong youth bring me ropes," the boy, offering two coils, replies, "O my father, here is rope for you." The third event above is that of the launching of a papyrus boat. In front of it is a more important construction—a boat of wood, rowed by many oarsmen and steered (also by means of oars) by standing helmsmen. At the end of the picture is seen the part of another boat disappearing in the shallow waters of a marsh. The papyrus skiffs were neither sailed nor, strictly speaking, rowed, but were propelled by long poles or by short oars with broad blades with which the boatman lightly touched the surface of the water.

Direct clinical evidence to the value of 'Iodolysin'

A soluble compound of 'Thiosinamin' containing 47 per cent. of Iodine, which has given strikingly successful results in the treatment of Rheumatism, Rheumatoid Arthritis and Arthritis Deformans

"NO AGENT SO EFFECTIVE."

"A lady was sent to me several months ago suffering from advanced Rheumatoid Arthritis. Knee, wrist and ankle joints were all affected. In a word she was a complete cripple. After six weeks treatment she was able to walk well and movement was possible in all joints which formerly were in a state of ankylosis. In my own opinion there is no medicinal agent so effective in the treatment of Rheumatoid Arthritis as 'Iodolysin.'" M.B.

"UNIFORMLY SUCCESSFUL."

"I have used 'Iodolysin' in a very large number of cases with uniformly successful results. Typical is that of a lady age 48 of obese habit. She was so affected as to be scarcely able to move. 'Iodolysin' in 20 minim doses was prescribed together with 'Iodolysin' Ointment for local application to the joints. She was completely relieved for the time and keeps well and free from pain when treatment is instituted for short periods every 18 months." M.D.

ENFORCED UNEMPLOYMENT REMEDIED.

"I am pleased to be able to testify to the very excellent results which I have obtained from a fairly extensive use of 'Iodolysin' particularly in cases of Rheumatoid Arthritis. Cases of long standing disability and enforced unemployment through stiff and crippled joints have been so much alleviated that they have been able once more to earn their own livelihood. The patients tolerate the drug perfectly well, and I have had no trouble with nausea or any unpleasant effects." M.D.

The Milroy Lectures

ON THE

INFLUENCE OF INDUSTRIAL EMPLOYMENT
UPON GENERAL HEALTH.DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON ON MARCH 9TH, 14TH, AND 16TH, 1922,

BY

MAJOR GREENWOOD,

READER IN MEDICAL STATISTICS IN THE UNIVERSITY OF LONDON;
FORMERLY STATISTICIAN TO THE LISTER INSTITUTE.

LECTURE I.

WITHIN the thirty-six years which have passed since the death of Dr. Gavin Milroy many aspects of *Stato medicina* have been examined by those to whom the College has accorded the honour of lecturing upon his foundation. Some—for instance, Dr. Boycott in his lectures on ankylostomiasis (1911), or Dr. Collis in his account of the etiology of industrial pneumoconioses (1915)—have had the privilege of describing evils to the amelioration of which their own researches were substantial contributions. Others—such as the late Dr. Bulstrode (1903) and Dr. Hamer (1906)—have brought ripe experience and wide erudition to bear upon more general and still unsolved problems.

The theme I have chosen—the direct and indirect influence of industrial employment upon health—involves the consideration of both solved and unsolved problems. I am conscious that neither by virtue of having contributed to the solution of the former, nor by intimate knowledge of the difficulties of the latter, am I well fitted to throw light upon so important a topic. But the topic is so important, the data are so numerous and so interesting, that the least competent lecturer can hardly fail to advance some propositions worthy of attention.

ANCIENT INDUSTRY.

Factory production, as we understand the term, is so novel, it is so short a time (measured in human generations) since our country was a self-contained agricultural state, that modern industrial medicine has but few traditions. To the founder of this College a description of twentieth-century medico-industrial problems would appear as monstrous, as grotesque, as the story of economic conditions in the nineteenth century seemed to John Ball in Morris's tale. We must pass back to the Roman civilization before we find anything even faintly analogous to our own times. Then we do reach a great population dependent upon imported food supplies; an external luxury and security which moved the envy of Gibbon; a complex social organization which, by the magnitude of its taxation and the multitude of its civil servants, might have inspired the indignant rhetoric of a Harmsworth.

Professor Frank of Baltimore has recently pointed out that an attempt to read into Roman history the economic motives of our time is doomed to failure, but he has likewise shown to how great an extent industrial mass production—factory production—entered into the system of life. In Rome—as indeed in England down to a time covered by the lives of some still with us—the base of the system was agricultural; the organization of the villa became capitalistic before the end of the Republic. After the conquest of Sicily, agricultural production was diverted into channels and adopted methods which remind us of what happened in England during the first half of the sixteenth century. Cattle raising and olive cultivation tended to replace tillage for cereals, and the main source of food was no longer at home. Before the time of the Empire one form of the modern population question had become acute; the *plebs urbana* was the counterpart of our urban "proletariat." With the change of system, the task of keeping alive a population superfluous for agriculture and no longer so urgently needed for foreign wars provided an opening for industrial organization. This organization developed, but capriciously and incompletely. The best instance of monopolistic mass production is that of brick making; the great property of Domitius Afer, which ultimately passed by inheritance to Marcus Aurelius and became an imperial trust, is a good example. To take another instance, the table ware of Arretinum was widely disseminated; factories in the valley of the Po supplied all the empire except the south-east (Frank, p. 168); ultimately branch factories in Gaul swamped the parent establishments. The scale of produc-

tion was large; a Cornelius had forty designers, Calidius Strigo at least twenty. Brouze and copper ware also seem to have been manufactured on a large scale, while other examples could be given. We are thus assured that a citizen of the Roman Empire must have been familiar with some of the conditions of industrial life; yet no ancient writer has attempted to describe that life.

I suppose that anyone who reads the Roman classics with enough scholarship to overcome the mere obstacles of a foreign idiom, but with too little to be attracted and charmed by linguistic delicacies, perceives the essential inhumanity of the humbler letters, the narrowness of the range of life. Sometimes the vituperation of a slave in comedy—for example, the speech of Olympos in *Casina*, Act I, 117 et seq.—or a thumbnail sketch of an interior, such as that of the mill in Apuleius (*Metam.*, IX, cap. 12, p. 197 of van der Vliet's edition), reveals the hardship and squalor which formed the background of recorded history, but that is all. To quote Macanlay—a philistine, no doubt, but a learned one—"there is a great gulf [between us and the Romans] which no learning will empower a man to clear. Strength of imagination may enable him to create a world unlike our own; but the chances are a thousand to one that it is not the world which has passed away" (Trevelyan, p. 369). Roman literature as an instrument of culture has had many hard things said of it—the hardest and the truest would be that it is often theatrical and nearly always snobbish.

These vices have not only diminished the historical value of the lay writers; they have tainted professional literature. We all know what Cato and the elder Pliny thought of physicians. A greater than either, Tully himself, has indeed allowed a kind of respectability to arts such as medicine of a certain value (*non mediocris utilitas*), but only provided they are practised by persons to whose station in life they are suitable (*is quorum ordini conveniunt: de Off.*, I, cap. 42). A society which thus esteems physicians will have the physicians it deserves; one gathers from Sir Clifford Allbutt's great work how small those deserts were. Galen practised in Rome for many years and wrote a large treatise on hygiene; not the least celebrated of his books and of special interest to the College, for it was one of those translated by our first president into a Latin esteemed by Erasmus superior to the Greek original. Indeed many worse books on hygiene have been written; Galen's remarks upon physical exercise would secure approval to-day, and if by hygiene we might understand the regulation of the lives of those who may do what they please, we could not wish for a better teacher. Galen makes it perfectly clear that this is the only social class with which he is concerned. He says:

"What is literally speaking the best cannot be attained in all lives, for the greatest part of mankind live encumbered by affairs which most needs injure those engaged in them and are unable to change their condition. Some are driven by poverty to this way of life, others by servitude entailed by inheritance or imposed by force. These indeed according to common speech are the only forms of servitude, although for my part I hold that those who, urged by ambition or cupidity, encumber their lives with occupations which leave them insufficient leisure to care for health are really slaves of the worst kind of masters. To lay down rules of hygiene for such persons is idle. But if anyone by luck or design is free, to him it is proper to describe how he may be healthy, may be tried as little as possible by disease and may grow old agreeably" (*de San. Tuend.*, II, 1, Kuehn, VI, 82).

The only hygienic prescription for the "greatest part of mankind" which I have found in this treatise is a recommendation to common folk whose bodies are full of crudities to take a purge on holidays instead of making matters worse by intemperance and the consumption of bad food (see Book VI, 7, Kuehn, p. 412). This is a modest contribution to the art of industrial hygiene. When, more than fifteen hundred years later, Bernardino Ramazzini² said that it was unworthy of a practising physician to amuse himself with trifles, he may have had, if not Galen, at least some Galenists in mind. When he added: "I have thought it highly serviceable to the State to submit the diseases of artificers to a diligent examination, which until now nobody has devoted to them, and to prescribe their appropriate remedies," he claimed nothing but his rightful priority. The hygienic lessons which might have been learned from centuries of industrial experience in the Roman world were not learned, or at least were not transmitted to posterity. When towards the end of the eighteenth century our profession was again faced by the hygienic difficulties which the aggregation of handworkers divorced from agriculture imposes upon

² See the preface to *de Morbis Artificum Diatriba*, second edition; p. 272 of the edition of his works printed in London in 1717.

social life, ancient medical literature, to which great prestige still attached, could teach it nothing. This is one of the reasons why the writings of physicians on industrial disease, down to the beginning of the nineteenth century and even beyond, are less valuable than, recalling the rich field of observation, we should have expected.

THE HEALTH OF THE WORKING CLASSES AT THE END OF THE EIGHTEENTH CENTURY.

Although there was difference of opinion as to whether the condition of the people at the end of the eighteenth century were worse than it had been at some time, there was none as to the proposition that it was absolutely bad. Burke was not an "agitator," yet he spoke of the "innumerable servile, degrading, unseemly, unmanly, and often most unwholesome and pestiferous occupations, to which by the social economy so many wretches are inevitably doomed," and added this remarkable passage:

"If it were not generally pernicious to disturb the natural course of things, and to impede, in any degree, the great wheel of circulation which is turned by the strangely directed labour of these unhappy people, I should be infinitely more inclined forcibly to rescue them from their miserable industry, than violently to disturb the tranquil repose of monastic quietude. Humanity, and perhaps policy, might better justify me in the one than in the other. It is a subject upon which I have often reflected, and never reflected without feeling from it" (*Reflections on the Revolution in France*, Payne's edition, p. 190).

The medical history of the great industrial districts during this period is an incident of one of the classics of British medical scholarship, and a story which Dr. Charles Creighton has told nobody need tell again. We find very large populations herded together in circumstances peculiarly favourable to the dissemination of contagious disease, and consequently we have a gloomy succession of typhus, relapsing fever, and small-pox. I permit myself but two remarks—the first is to emphasize the truth contained in the following words of Creighton:

"The long period of comparative immunity from typhus near the beginning of the nineteenth century was first broken, both in Great Britain and in Ireland, by the very severe winter of 1814-15; but it was not until the great depression of trade following the peace of 1815 (which made a difference of forty millions sterling a year in the public expenditure) and the bad harvest of 1816 that typhus fever and relapsing fever became truly epidemic, chiefly in Ireland but also in Scotland and England. The lesson of the history is unmistakable: with all the inducements to typhus from neglect of sanitation in the midst of rapidly increasing numbers, there was surprisingly little of the disease so long as trade was brisk and the means of subsistence abundant. The reckoning came in the thirty years following the Peace" (Creighton, II, 167).

We are apt to forget that the penalty of sin against the laws of hygiene is rarely exacted at once. We cannot rightly appraise the significance of current rates of mortality or morbidity unless we know what went before; that is why medical history is worth studying.

The second remark is that as early as 1796 it had been realized by some that poverty was not the only factor of industrial ill health, that it was not entirely because factory hands were wretchedly lodged, clothed, and fed that they died in such myriads. These points are quite clearly taken in the resolutions submitted to the Manchester Board of Health by Dr. Percival on January 25th, 1796 (see *Select Documents*, p. 495). The first asserts that those working in factories are "peculiarly disposed to be affected by the contagion of fever," and that infection so received is liable to be propagated outside the factory. The second and third are as follows:

"The large factories are generally injurious to the constitution of those employed in them, even when no particular diseases prevail, from the close confinement which is enjoined, from the debilitating effects of hot and impure air, and from the want of the active exercises which nature points out as essential in childhood and youth, to invigorate the system and to fit our species for the employments and for the duties of manhood.

"The untimely labour of the night, and the protracted labour of the day, with respect to children, not only tends to diminish future expectations as to the general sum of life and industry, by impairing the strength and destroying the vital stamina of the rising generation, but it too often gives encouragement to idleness, extravagance, and profligacy in the parents, who, contrary to the order of nature, subsist by the oppression of their offspring."

These resolutions enunciated for the first time the proposition that in addition to the bringing into existence of slum populations, one could find in the immense numbers of persons in conditions noxious to

century receive the attention it deserved, that it is nearly true to say that the close study of intrinsic factory hygiene has been postponed to our generation.

THE EARLY NINETEENTH CENTURY.

In his history of English sanitary institutions Sir John Simon devoted a chapter to the "Growth of humanity in British politics," because he perceived that a quickened sense of humanity, or an uneasy social conscience, was very largely the motive of the public and private inquiries during the first forty years of the nineteenth century which produced the legislation of Queen Victoria. No less powerful motive would have sufficed to call into being the large amount of literature which appeared—especially between 1830 and 1850. The general historical value of this material is great, but from the medical side it is inevitably defective. Very few people can reason well when they are angry, even when they are righteously angry; attack provokes defence or counter-attack; in presence of social evils a generous-minded man acutely conscious of these evils is sorely tempted to use any intellectual weapon to his hand, and to forget the story of Eli's sons. Then, again, nobody can free himself from the empire of intellectual theories, the idols of the study. These shortcomings, absolutely inevitable shortcomings (we do not see them in our own researches, but the Milroy lecturer of 2022 will point them out), are obvious enough in the reports of committees and commissions of inquiry eighty or ninety years ago. Here we are interested chiefly in the intellectual side of the work, and its defects, I think, may be resumed under two headings: (a) an inadequate grasp of the statistical method; (b) a failure to escape from Galenic realism. The former defect was, I think, the more serious. It was not until after most of the reports to which I refer had been completed that we possessed accurate statistics of mortality through which we could relate deaths to risk. Wanting these data, appreciations of mortality could only be obtained indirectly, and the limited value of the indirect methods was not always perceived by those who used them. The pioneer investigators, Thackeray of Leeds and Edwin Chadwick, almost exclusively based conclusions as to the comparative healthiness of different localities or trades upon confrontations of the mean ages at death. Although the fallacy of this method seems to us very obvious, and had been already exposed at the time to which we refer by both Neison and Farr, little notice was taken of the criticisms, with the result that many of the statistical tables printed by Chadwick are of very small value. Another indirect method of assessing the importance of particular causes of deaths, that of comparing the proportion of such deaths to all deaths in several trades or localities, which was also extensively used, although less objectionable, can only be trusted if precautions are observed and subsidiary tests employed which the early Victorian writers neglected. These statistical errors were imposed upon the inquirers by the nature of their data, and the only blame attaching to them is that they were too chary of self-criticism, a charge on which a verdict of guilty will be returned against all of us on some future day of reckoning. These criticisms are directed to the attempts to estimate English regional or occupational mortality during the years of the nineteenth century before the establishment of the General Register Office; we must, I think, deem them unsuccessful attempts and confine ourselves to the years following 1838 so far as the discussion of mortality is concerned.

But the General Register Office has necessarily been restricted to the study of births, marriages, and deaths, while the various commissions and committees of the early and mid-Victorian age printed much evidence of a statistical character dealing with the morbidity, physique, housing conditions, and factory conditions of the working classes. These data are ample to establish the existence eighty years ago of a vast amount of unwholesomeness—enough to justify the severest strictures of Chadwick and Simon. They are not, however, sufficient to sustain a comparison between the circumstances of the industrially employed and the rural populations of the time, owing to errors of method. When it is not possible to examine all the members of the "universe" under consideration—this possibility is only realized in a complete census and then only for very simple characters—one is forced to adopt the method of sampling, and the validity of inferences drawn from the examination of the samples depends upon (1) a satisfactory assurance that the sampling has been random or, if not random, that the bias

can be characterized, and (2) measurement of the probable range of random fluctuations of sampling. In the best recent sociological inquiries, such as those of Professor Bowley and his colleagues, to which I shall again refer, the importance of these considerations has been realized. This was not so eighty years since. A good deal of the evidence tendered consisted of the opinions of "experts" resting upon experience the sufficiency of which cannot be determined. Many of the statistics relate to small collections of data reduced to categories the significance of which may have varied, and probably did vary, from observer to observer. To attempt to deduce from these fragments any measure which shall confirm or weaken the teaching of mortality statistics is, I fear, a hopeless undertaking. I can illustrate the difficulties from a recent instance.

The Ministry of National Service issued in 1920 an analysis of the results of physical examination by medical boards from November 1st, 1917, to October 1st, 1918. The information contained in this report is enough to prove that the absolute volume of physical inefficiency in this country is enormous; the simple fact that out of 2,425,184 examinations or re-examinations more than a quarter of a million men were found to be "totally and permanently unfit for any form of military service" is a very dreadful fact, explain it how we may. But the authors of the report did not confine themselves to the recital of these facts; they deemed it "probable, therefore, that the men examined during the year under review may be regarded in the aggregate as fairly representing the manhood of military age of the country in the early part of the twentieth century from the standpoint of health and physique." In other words, they claimed to have fulfilled the requirements of random sampling.

Down to October 31st, 1917, and after August 4th, 1914, the War Office had recruited in England and Wales 3,190,618 men for general service and 615,365 men for other grades—that is, 3,805,983 men mainly between the ages of 18 and 40 had been excluded from the Ministry of National Service's field of sampling. From a consideration of the enumerated population in 1911 and the rates of mortality, I should suppose that between 6,800,000 and 7,200,000 men came within the limits of 18 and 40 during the period of War Office recruitment. The War Office had already dealt with the population. What are the grounds for the sample? The Ministry of National Service's arguments:

1. In the early days of the war many unfit men were passed as fit owing to haste and ill-considered methods of examination.
2. A very large number of men were at first protected, and those protected industries "employed an abnormally high proportion of the physically fit."
3. Men were examined who "had been previously rejected when the need was less urgent."
4. A large proportion of lads attained the age of 18 during the war.

5. A certain number of men between the ages of 41 and 51 first became liable for service under the Military Service (No. 2) Act.

That portion of the Ministry's experience which relates to youths who attained the age of 18 after October 31st, 1917, is, so far as selection by the War Office is concerned, not biased; men between 41 and 51 in protected industries were not, I think, examined. To admit the wider claim is to accept the first three propositions. Of these (2) might be partially verified; the mortality at military ages of coal-miners and of agricultural workers is less than the average; whether this is true of other protected industries is a question I cannot answer, nor does it receive any statistical discussion in the Report. Propositions (1) and (3), which assume the existence of two biases, the one tending to raise, the other to lower the proportion of unfit men removed from the population or added to it, seem to me quite incapable of being tested. The mere fact of the existence of the former bias, which the Report states to be "notorious," and of the latter, the existence of which was within the direct knowledge of the Ministry of National Service, must, as I think, deprive the data—with the exception just noticed—of any claim to be regarded as random samples of manhood of military age; at the most there was a random sampling of youths of 18. It is no strong argument in favour of the accuracy of a sum total to be able to say that two of the items cast are wrong, and to surmise that their errors may cancel out. (See par. 54, p. 24, of the Annual Report of the Chief Medical Officer of the Board of Education; Cmd. 935 of 1920.)

Perhaps data exist to establish the propositions which I suggest are doubtful; in any event the subject can be discussed *viva voce* . When similar uncertainties attach to the data of two generations ago, we cannot pass behind the printed words and must neglect what we think needs verification.

The other defect of the earlier literature is historically interesting, but may be dealt with more briefly. Galenical etiology put the maximum of stress upon the all-embracing atmosphere, its catastrophes and their operation upon men's bodies leading, when an appropriate dyscrasia existed, to humoral corruptions. In time the doctrine—not originally, as I have tried to show elsewhere, unreasonable—became, like the peccant humours themselves, extremely corrupt; the belief in some putrefaction or subtle organic impurity of the

air—a notion which survives in the belief in the etiological importance of sewer gas—dominated scientific opinion until late in the nineteenth century. Simon, writing in 1858 of typhus, held that "the exhalations from a patient undergoing it are, till they have been neutralized by dilution with pure air, capable of communicating the same form of disease" (Simon, 1445), and adds a footnote explaining the susceptibility and powers of transmitting the disease of the famine-stricken by the emaciated condition of their tissues and juices, an explanation which would have been acceptable to Galen.

Our grandfathers had, of course, grasped the importance of an etiological factor which Galen mentioned but slighted; they were fully awake to the dangers of water or food supplies liable to contamination with excremental matter. But, after making this extremely important exception, one finds little in their etiology which would have been strange to Linacre. This, I think, is the reason why, next to water and drains, ventilation—and ventilation in a rather restricted sense of the term—was the staple of Chadwick's and Simon's reports. This preoccupation caused them to miss etiological factors to which we are now beginning to attach importance, especially, perhaps, the physiologic-psychological predisposing causes of ill health. But, since ventilation, expressed in terms of a wider philosophy than the Galenical, is still recognized to be of the highest importance, what was lost was not perhaps much.

METHODS OF INVESTIGATION.

I have now brought the story down to an epoch from which into our generation a continuous statistical record exists. As a loyal member of this College, mindful of the importance the College attaches to the study of historical origins, whether of theory or practice, it was my duty to describe, however imperfectly, the fragments of early experience handed down to us. What remains must be examined with more precision, and I shall first indicate the manner in which, as I think, one ought to proceed.

In the first place, we may adopt the historical-statistical method. We know that this country, already a great industrial nation seventy years ago, has become more and more industrialized. It no longer, indeed, enjoys—if that be the fitting expression—the industrial hegemony of the world, but in each successive decennium a larger proportion of its citizens have spent their lives in industrial pursuits. Hence our records of mortality are those of a continuously changing community, the change being one of increasing urbanization. The changes in the extent and distribution of mortality are changes highly correlated with industrialization. These must therefore be examined both as a whole and in the several divisions of the country which have been more or less immediately concerned in industrial development.

But unless we can place beside this chronological record that of some other country wherein the economic development has differed very much from that of England and Wales, we shall be unable to draw any conclusions as to the influence of industry upon the changes in the public health which our mortality registers indicate. For this purpose I employ the vital statistics of Sweden, a country the statistics of which are nearly as valuable as our own, and have been published regularly for a much longer period. Seventy years ago Sweden was almost wholly an agricultural and maritime state; at a time when more than half our population was already urbanized not more than 10 per cent. of the Swedes lived in towns (Hendriks). In the last forty years industrialization has notably advanced in Sweden, and now almost half her people live by industry; even now, however, there is relatively much less factory employment in Sweden than in England and Wales.

But the historical-statistical method, even with the help of such a control series as here utilized, is impotent to provide answers to all our questions. In no other branch of statistics is the method of multiple correlation more needed or more difficult to employ. We must have resort to the method of contemporaneous comparisons and must contrast the industrial and non-industrial sections of the population observed over one and the same period, that period being our own generation. It will soon appear that even this method is treacherous, that there are numerous etiological factors which available data leave obscure. Indeed, my analysis raises more questions than it settles, and, chiefly for that reason, I exclude technical discussions to which, as a statistical epidemiologist, I attach importance.

THE VICTORIAN AGE.

In the Supplement to the thirty-fifth Annual Report of the Registrar-General, almost the last and one of the finest contributions to official literature of Dr. William Farr, there is a table, which I reproduce (Table I), of the death rates at

TABLE I.—Annual Mortality per Cent. of Males and Females in England and Wales.
(Supplement to 35th Annual Report of the Registrar-General, p. xxvi.)

Ages.	Males.		Females.	
	1838-54.	1838-71.	1838-54.	1838-71.
All ages ...	2.33	2.33	2.17	2.15
0 ...	7.25	7.25	6.23	6.17
5 ...	0.92	0.57	0.91	0.95
10 ...	0.52	0.49	0.51	0.50
15 ...	0.82	0.78	0.15	0.80
25 ...	1.00	0.93	1.06	1.01
35 ...	1.28	1.30	1.17	1.23
45 ...	1.25	1.85	1.59	1.56
55 ...	3.18	3.20	2.82	2.89
65 ...	6.69	6.71	6.00	5.89
75 ...	14.76	14.71	13.44	13.43
85 ...	30.14	30.55	27.52	27.95
95 ...	44.03	44.11	43.22	43.04

ages for the seventeen years 1838-54 and for the whole available period 1838-71. It will be noticed that from the age of 5 to the age of 25 the death rate of males is slightly lower in the second than in the first half of the table, but from 35 to 75 the two rates are either equal or that of the complete series is higher. The death rates of women exhibit a decline at each age above 5. In the middle period of life male mortality either did not improve or somewhat deteriorated over this series of thirty-four years. These are the rates of all England and Wales, and, since the agricultural population was declining, are increasingly weighted by the experience of the industrial districts. In Table II are set out some details of contrasting areas selected from the ninth Annual Report of the Registrar-General and from the first two decennial supplements. It will be seen that, with the exception of the registration district of Manchester, mortality at ages 10-15 was less in 1861-70 than in 1838-44. This is also true of the ages 15-20 and 20-25, but not generally true of later maturity. Take as an example the age group 45-55, and compare the South-Western Registration area, which included, and still includes, a large proportion of agriculturally employed persons, with the great industrial districts of Birmingham and Manchester. The South-Western rate on males was in 1861-70 almost the same (not quite 2 per cent. higher) as in 1838-44. So was the Birmingham rate (a decrease of less than 1 per cent.). The ratios of the two rates were 1.77 to 1 in 1838-44, 1.73 to 1 in 1861-70. The female rates were in the proportion of 1.50 to 1 in the former and of 1.62 to 1 in the latter period. Manchester emerges still worse from the comparison; the ratios are 1.95 and 2.18 for males, 2.20 and 2.35 for females. Contrast these with the rates upon adolescents. The mortality of males aged 10-15 in Birmingham was in 1861-70 only 79 per cent. of what it had been in 1838-44, of females 78 per cent. The adolescent mortality in the South-West had improved, but not so much—86 per cent. and 81 per cent.; so that the ratio of town to country fell, 1.21 to 1.11 for males, 1.07 to 1.03 for females. This is a different picture, but Manchester makes an even worse showing than in ages of maturity; her ratios to the South-Western are 1.27 and 1.70 males, 1.34 and 1.40 females. We must be careful not to attach great importance to particular instances; even our national vital statistics are to be used with caution or we are entangled in the snare of realism. We all know how increasingly untrustworthy as measures of mortality in the capital the old bills became, because London "within the bills" grew less and less typical of London as an economic or social unit. The same difficulty is met when we compare any registration district at intervals of many years. The

name persists, the proportion what is measured bears to what we think we are measuring changes. I believe we may infer from these statistics no more than that in those palmy days of industrial supremacy which followed the repeal of the Corn Laws adolescent mortality in the whole population improved, while the mortality of adults did not improve but even deteriorated, and deteriorated more in the industrial districts than in the agricultural areas. But perhaps this was a world phenomenon purely accidentally correlated with the growth of modern industry. To settle this we must extend our horizon and take notice of the changes in some other country where, during this period, industrial employment was unimportant. In Table III the statistics of England and Wales are compared with those of Sweden; I shall have to mention these again later, now I invite attention to the parting of the ways between Sweden and ourselves; within this period Swedish mortality during ages of maturity at first higher than ours, crossed the English line in its descending path and established a superiority which has ever since characterized it. If we now recur to the social-hygienic progress of the time some correlative facts are noteworthy. Nearly all the legislation relating to industrial employment before the reign of Victoria was intended to shield children and young persons

TABLE III.—Rates of Mortality in England and Wales and in Sweden.

Ages:	MALES.						FEMALES.					
	15-20.		20-25.		25-35.		15-20.		20-25.		25-35.

from ill treatment, by the horrors of which "even the methodical and dry language of official documents is startled into life" (Gibbins), and it was not until 1833 that these victims received the protection of State-appointed inspectors. It was not until 1847 that the Ten Hours Act, which still only applied to *female* adults, did indirectly shorten the hours of labour of men. But this Act, as the provisions of and discussion upon an Act of 1850 indicate, was often evaded, and it is substantially correct to say that the Factory Act of 1867 was the first to deal with the matter on a really wide scale.

This Act brought within its scope all the metal trades, foundries, engineering shops, the manufacture of paper and of glass, the tobacco industry, and printing. It also provided that any place in which fifty or more persons were industrially employed should be deemed a factory. A few years before this Greenhow's studies of industry and disease had been published in the medical reports of the Privy Council, and, as Professor Collis and I have suggested elsewhere (Collis and Greenwood, p. 33), the provisions of the Act respecting the removal of injurious dust may well have been motivated by Greenhow's researches.

In this year, too, the first Workshops Act was passed, regulating the conduct of industrial establishments employing less than fifty persons. Young persons and women might only be employed for twelve hours, less half an hour for meals, and no protected person might be employed after 2 p.m. on Saturdays. The duty of enforcing this Act was not, however, laid upon the State inspectors until 1871.

We see, then, that industrial health legislation almost to the end of the period we have been considering only concerned protected persons—women and children—that the Act which indirectly affected the working conditions of adult men only became fully operative within a year or two of its close.

With these facts we may correlate the stagnation—if not worse—of adult mortality. After this period, after indirectly effective legislation dealing with adult labour, the rate of mortality at ages of maturity did decline. Put into other words, the story is this: The generation from 1837 to 1870 was, hygienically speaking, characterized by (1) a very considerable improvement of public sanitation, in particular of urban water supplies; (2) a reduction of hours of labour and an improvement of the conditions of industrial work amongst "young persons" and women. There was also improvement, but, to judge by still existing conditions, not a very great improvement, of the domestic housing of the working classes. Both (1) and (2) would be expected to produce their greatest effects upon mortality at ages between, say, 2 and 20 (in childhood and adolescence). The conditions of domestic insanitation which multiply infant deaths were not improved; the factory laws only helped the young persons and women, and a large proportion of the industrially employed women were and are young women. Hence the stagnation of mortality in the earliest years of life and after adolescence, together with the improvement in later childhood and at adolescence, may be consequences of what was done and what was left undone. One of our greatest sanitary triumphs has been over water-borne diseases such as typhoid. At the period under notice typhoid was not statistically distinguished from typhus; in 1851-60 the combined group was responsible for 14.1 per cent. and 12.8 per cent. of all deaths at ages 10-15 and 15-20 (males), but for less than 5 per cent. of deaths at ages over 35. But this recital does not authorize us to replace correlation by causation.

No student of medical history doubts the truth of Bishop Butler's words: "What a wonderful incongruity it is for a man to see the doobfulness in which things are involved, and yet to be impatient out of action, or vehement in it." And Dr Creighton's interpretation of the epidemiology of

plague in the light of Pariset's theory; none of the rich, the exhaustive series of facts but is perfectly congruent with the theory; the pieces fit together like the elements of a jigsaw puzzle. Yet we all recognize now that Pariset's theory is false. The condition that a hypothesis shall describe all the available facts is necessary to its validity but is not sufficient to guarantee it more than a provisional value. We have to bear this in mind when we seek to interpret the vast complex of industrial phenomena. We are to remember that an industrial community attracts to itself immigrants both from the non-industrial districts of the country within which it is situated and from other countries, and subjects these migrants to a new form of environmental selection.

In Dr. Perry's study of one of the great seats of the American cotton manufacturing industry it is shown that the incidence of mortality upon workers of different races varies enormously. The general death rate per 1,000, at ages 15-45, over the period studied (1908-12) was 6.97 amongst Americans, 8.31 amongst English, and 17.26 amongst Irish (p. 238). This is perhaps an example of the consequences of introducing an "unsalted" population to factory life of which I shall speak later. But as the supply of home-born labourers increases and migration relatively decreases it might be that the incidence of excess mortality would be shifted to the later ages. It might be that the phenomenon to which I have drawn attention is rather due to a change in the character of the population than in the nature of their environment. To study this matter we should need data which do not exist; the possibility can be stated, its probability cannot be measured. Still there is one set of facts which, though by no means decisive, is yet of importance.

I have already commented upon the unfavourable comparison between our mortality in later ages and that of Sweden, and the favourable contrast between our adolescent mortality and that in the Scandinavian countries. More will be said of this; now I would remark that, in the opinion of many Swedish medical men and statisticians, the extremely unfavourable position between the ages of 15 and 25 is attributable to industrial employment. It is noteworthy that Swedish industrial legislation for the protection of young persons in the matter of length of hours, night employment, etc., is still less stringent than our own and only became really effective within the last twenty years; that is to say, that the rising importance of Swedish industries which has been associated with a stagnation of mortality at adolescent ages did not, as did the Victorian growth of factory industry, produce either so early or so complete a legislative interference in the interests of national hygiene as we have experienced. Again I repeat the caution that other explanations are possible. Still it is a fact that the country in which growing industries were accompanied by hygienic control of juvenile labour experienced a declining juvenile mortality; the country which introduced such control late in time has had a stationary juvenile mortality.

EXCISION OF THE HEAD OF THE FEMUR IN ARTHRITIS DEFORMANS (OSTEO-ARTHRITIS) OF THE HIP-JOINT.*

BY

HARRY PLATT, M.S., F.R.C.S.,

HONORARY SURGEON AND SURGEON-IN-CHARGE, ORTHOPAEDIC SERVICE,
ANCOATS HOSPITAL, MANCHESTER; CONSULTING SURGEON, GRANGE-
THORPE HOSPITAL (MINISTRY OF PENSIONS), MANCHESTER;
LATE HUNTERIAN PROFESSOR OF SURGERY, ROYAL
COLLEGE OF SURGEONS OF ENGLAND.

THE variable terminology of chronic joint diseases has been productive of much confusion, but it is well recognized that the chronic "non-specific" joint diseases of adult life fall into two great groups—the rheumatoid and the osteo-arthritis—each presenting a clinical picture and a train of morbid joint changes of a distinctive type. Both were formerly included under the term "arthritis deformans," but should properly be regarded as separate clinical and pathological entities; if the term is retained it is more applicable to the osteo-arthritis class alone, for it is here that bony deformation of the articular ends is a conspicuous feature.

We may thus define osteo-arthritis of the hip-joint as a chronic monarticular lesion, the dominant pathological changes being of a hypertrophic nature as indicated by the development of marginal osteophytic deposits with expansion

and mushrooming of the femoral head, but with no tendency towards the production of true ankylosis. The term "morbus coxae senilis," often applied to this affection, is a misnomer. The clinical, pathological, and radiographic pictures of osteo-arthritis of the hip may be seen at varying periods of life: in the adolescent, in the young adult, in middle life, and in old age. It is, however, in the middle-aged individual that we encounter the fully matured arthritis with its consequent serious crippling and disablement.

ETIOLOGICAL CONSIDERATIONS.

A review of some forty cases under observation and treatment during the past few years seems to show that osteo-arthritis of the hip can be classified into three more or less arbitrary groups.

1. *Infective*.—In this group there is definite evidence of the continued existence over a long period of time of some active focus of infection, this in the majority of instances being sepsis in connexion with the mouth or nasal passages. In these patients the joint changes are often far advanced in early middle life.

2. *Traumatic*.—Under this heading are included those cases of osteo-arthritis of the hip which appear to follow the infliction of a single severe trauma. In a certain number of cases this has been an actual crush fracture of the neck of the femur without immediate displacement; absence of displacement accounts for the fact that the patient is able to bear weight on the limb almost at once, and in consequence the actual lesion may escape diagnosis. In this class of case there is invariably a latent period between the infliction of the injury and the onset of the subjective signs of arthritis; and it is usual for the patient to consider that complete recovery from the accident had occurred. The age incidence in this group tends to be higher than in the infective class. The end result of this type of incomplete fracture may be contrasted with the hip-joint disability seen in cases of non-union following a complete solution of continuity of the femoral neck.

3. *Secondary*.—The third class comprises those cases in which there is seen to be the development of signs of progressive arthritis in a hip-joint which at an earlier period—in childhood or adolescence—has been the seat of some deforming process, such as pseudo-coxalgia or arthritis deformans juvenilis. These hip-joints from early life have exhibited a structure departing from the anatomical normal, but there has been a period of complete quiescence from symptoms until in later life certain influences, such as infection, trauma, or chronic strain, provide the necessary etiological factors to initiate a renewal of active arthritis.

The separation of these different groups is somewhat artificial, for it is probable that in the majority of cases of osteo-arthritis of the hip-joint the actual etiology is complex and represents the interplay of a combination of factors.

CLINICAL CONSIDERATIONS.

I shall not give a long description of the ordinary clinical features, pathological changes, and radiographic signs characteristic of osteo-arthritis of the hip-joint, but will content myself by briefly emphasizing certain important clinical aspects of the typical case.

Early Stages.—In the early stages the outstanding symptom is the long persistence of severe pain localized to the region of the hip-joint, and referred along the distribution of both the sciatic and anterior crural nerves. Many of these patients are diagnosed as suffering from so-called sciatica, and receive the whole gamut of inappropriate treatment for a long time before the underlying lesion is discovered; it is therefore important that an early efficient physical examination of such a patient should be made. There are certain difficulties in the way, for at this period the early bony changes may be relatively inconspicuous or invisible even in the best radiograms; again, in obese individuals it is no easy matter to obtain good hip-joint skiagrams. It should be unnecessary to insist on the futility of interpretations derived from the examination of a radiogram of one hip-joint alone without comparison with its fellow. In the earlier stages of the disease the limitation in the mobility of the joint is comparatively slight; it usually affects the range of abduction only, but in some cases the movements of flexion and internal rotation also. The patient himself is often soon aware that a restricted mobility has developed because of his inability to bend down in comfort to take off or lace the boot on the affected side.

Later Stages.—In the later stages there is a progressively increasing fixation and deformation of the hip-joint structures. Although the resulting fixation of the hip-joint may appear at first sight to be complete, it is even in an advanced stage dependent partly on the existence of muscular spasm, as examination under an anaesthetic will prove. The hip-joint follows its usual plan of reproducing the classical malposition of flexion and adduction. By this time the radiographic signs are gross enough to be apparent at the first glance, and they confirm the knowledge derived from clinical examination, that in spite of an advanced deformation of the joint surfaces true fibrous or bony ankylosis has not occurred. From the patient's point of view it is a pity that ankylosis is not reached in a short time, as it would lead to cessation of the intolerable pain.

I have indicated the course of the average severe case in which the resulting disablement is dependent on a combination of two dominating factors—namely, a continuance of severe pain and a steadily increasing fixation of the hip-joint in malposition. It is not every case, however, which advances to such a marked degree of deformation; in some patients the bony changes are arrested at an early phase, and associated with these changes of lesser magnitude the clinical features are often relatively mild.

TREATMENT.

It is illogical to suppose that the administration of this or that drug combined with the local application of the various forms of balneotherapy or physiotherapy can influence the train of morbid changes in a hip-joint already the seat of arthritis. It is not denied, however, that such measures are efficacious in producing temporary relief of the subjective signs. Given the recognition of early arthritis, a period of complete rest with immobilization at the hip-joint in the correct position of abduction, followed later by the provision of a suitable walking splint designed to eliminate full weight-bearing, will tend to prevent or at least arrest the development of gross deforming bony changes. It is assumed also that if the determining etiological factor is infection, complete eradication of every discoverable focus will be carried out.

In the practical handling of osteo-arthritis of the hip-joint, however, the critical period at which the ideal early preventive treatment is applicable is often long past, and we are called upon to deal with the serious disablement of the later stages. It is then that the question of the value of operative treatment becomes of paramount importance to the patient.

Operative Treatment.

Four main classes of operative procedure have been employed: (1) Manipulation under anaesthesia; (2) the simple removal of osteophytic deposits; (3) surgical fixation of the hip-joint—that is, arthrodesis; and (4) simple excision of the head of the femur. Great care and judgement must be exercised in choosing patients for operation, and it is necessary in each case to have a clear conception of what constitutes the essential disability from the patient's own point of view. This may be either pain or progressive deformity, or a combination of the two. Within certain limits age alone does not constitute a standard of suitability or unsuitability. In my own series excision of the head of the femur has been performed in an individual aged 61, and in another aged 65, with results quite as satisfactory as in younger patients. Patients for operation should be robust or "wiry," capable of tolerating the minor discomforts of post-operative immobilization and of early post-operative physiotherapy, and endowed with a determination to collaborate with the surgeon in the long period of after-treatment which may be necessary.

1. **Manipulation under Anaesthesia.**—In the early or middle phases of the arthritic process, when the infiltration and thickening of the joint capsule is slight, when the osteophytes are scanty and plastic, and when the femoral head shows little or no deformation, forcible manipulation particularly directed towards the achievement of the full range of abduction is a therapeutic manoeuvre of extraordinary value. This procedure is eminently suitable for patients in whom pain has not been a prominent feature, but who are more especially concerned about the increasing limitation of mobility in the hip joint. Sir Robert Jones has long employed this form of treatment in picked cases with striking success. More recently Petré of Lund¹ has commented upon the undoubted efficacy of forced movements, which in his view should be powerful and painful! Manipulative treatment has no permanent curative effect, but from a symptomatic point of view its beneficial effects may last for several years, or even indefinitely where the arthritic process has undergone spontaneous arrest at an early stage.

2. **Excision of the Osteophytic Outgrowths.**—This operation is in some measure the open equivalent of the bloodless manipulation. Its rationale is founded upon the view that the limitation of mobility is chiefly dependent on the mechanical obstacles afforded by the presence of osteophytes. Removal of the hypertrophied lip of the acetabular roof was advocated as a definite limited operative procedure both by Sampson Handley and by Courcy Wheeler some years ago, and has been termed "cheilotomy." Occasionally the osteophytic growths in the acetabular region assume a somewhat bizarre form, and arise from the floor of the cavity itself, thereby producing greater interference with mobility than the commoner hypertrophied acetabular margin. Their operative removal has been recorded by Brackett of Boston, who also in a number of cases carried out independently an operation of a similar nature to the cheilotomy of Handley and Wheeler. On the whole the operations in this category are of very limited application. The operative exposure of a good many of these hip-joints has impressed on me the fact that the ordinary osteophytic deposit on the acetabular rim plays a small part in producing limitation of mobility.

FIG. 2.—Illustrates the conformation and position of the hip-joint at the end of the operation.

3. **Arthrodesis.**—The operation of surgical fixation of the hip-joint for osteo-arthritis has been warmly advocated by Albee and given a very efficient trial by Brackett. Designed to transform a painful progressively stiffening hip into a painless fixed hip ankylosed in the position of maximum utility, the operation is, in theory, exceedingly attractive. An investigation into the out-comes of a series of hip-joint arthrodeses performed in Boston and published recently² has shown that a good many results have been disappointing, owing to the difficulty of obtaining solid bony ankylosis. Where complete fixation has failed the adduction malposition has returned and the functional result in such cases has been comparatively poor. Most surgeons who have attempted to perform arthrodesis on many hip-joints have experienced the same technical difficulty. Bony ankylosis can be ensured only after the complete removal of the whole of the smooth sclerosed bony tissue which represents the articular surface in these joints after the disappearance of the cartilaginous covering. The period of post-operative fixation must be prolonged and full weight-bearing postponed until it is determined by clinical and radiographic tests that true ankylosis has been secured. The scope of the operation and the necessarily prolonged after-treatment render it suitable only for younger individuals.

FIG. 1.—The shaded area of the femoral head indicates the amount which is removed at the operation; the line of section for the temporary elevation of the greater trochanter and the elevation of the aponeurotic flap from the vastus externus are also shown.

Excision of the Head of the Femur.

I now come to the operation which has engaged my special attention for some time past. Excision of the hip-joint or excision of the head of the femur has for a long time been one of the standard operations of surgery for many affections. Of late years it has fallen into disrepute, and deservedly so, for as performed in the old manner with complete lack of correct after-treatment the usual end-result was an unstable pathological dislocation. The operation flourished in the surgical epoch of excision of joints when surgeons were primarily concerned with the eradication of disease and operations were less commonly conceived in terms of function. The operation here designated "excision of the head of the femur," as applied to osteo-arthritis of the hip-joint and carried out in the manner to be described, is a somewhat different proceeding. It is fundamentally reconstructive, and not destructive, in type.

In brief, the operation involves the following steps: (a) The removal of the overhanging mushroomed portion of the femoral head, leaving the stump of the neck of a reasonable length and with a slightly expanded upper end rounded off so as to simulate a new head; (b) the stump of the neck is brought deeply into the acetabulum by fully abducting the limb; (c) the great trochanter, which has been detached as an integral step in the exposure of the hip-joint, is re-attached to the femoral shaft at a lower level, thus acquiring a position of mechanical advantage (Figs. 1 and 2). This latter manoeuvre is an important feature of the operation. I have used it only in my later operations and before I was aware that it had been already introduced by Royal Whitman of New York as part of his reconstructive operation on the hip for old fractures of the neck of the femur. There are other technical details of importance and interest. In removing the femoral head it is necessary to use a wide osteotome with a curved shaft in order to reproduce the rounded stump of the neck. The surface of the cancellous tissue thus exposed, after being smoothed off by filing, is thoroughly impregnated with Horsley's wax. The same procedure is carried out in the raw area left by the detachment of the trochanter. In addition, this latter area is covered by a small aponeurotic flap elevated from the vastus externus and turned upwards, leaving bare the femur in the region where the trochanter is to find its new site. With regard to the approach to the hip-joint used in this operation, in my experience the posterolateral route described by Brackett² is of all methods the most adequate.

After the operation the patient is nursed for six weeks on an abduction frame; the hip is completely immobilized by means of a fixed extension for the first three weeks only; after that gentle massage and active movements through a small range are given each day. In the intervals of treatment the patient is encouraged to repeat the attempts at active movement, the foot now being anchored to the lower part of the frame by a slack clove-hitch bandage. At the expiration of the six weeks' recumbency, if the patient has moved the hip with fair comfort (and this is usual), a calliper walking splint is applied and he is allowed to get up on crutches. A few weeks later full weight is borne on the calliper ring and the crutches discarded. The physiotherapeutic treatment is continued for some months, and the calliper splint is retained for at least six months; but in my experience the hip-joint is stable after three months, and the natural tendency of the patient is to discard the calliper at an early date.

The operation here described has given me exceedingly gratifying results, and for this reason has been described in some detail. I believe that it is applicable for the relief of the pain or malposition in moderately advanced cases of osteo-arthritis of the hip-joint at any age, provided the patient is constitutionally fit to undergo a major operation. There are few mechanical difficulties in the way of its fairly rapid performance; it takes less time and is less provocative of shock than an efficiently carried out arthrodesis. It is thus specially suitable for older patients, but my own trend at the present time is in favour of utilizing it also as an alternative to arthrodesis in younger individuals. The operation appears to give complete relief from the intolerable pain, and it also ensures the correction of the malposition. The degree of mobility in the reconstructed joint varies in different cases and under the influence of many factors. To some extent the range of mobility depends on the amount of bone removed in the resection of the femoral head—a factor which, as is well known, so often determines the function of any joint excision or arthroplasty. In a few individuals the range of

mobility, which is free in the early days after the operation, later diminishes very considerably, but this, happily, is not associated with any return of the old pain and discomfort.

It is not suggested that this operation is in any way original either in its conception or its application, but a somewhat intimate acquaintance with the technicalities involved in its performance and personal experience of its effectiveness have urged me to emphasize its place in the repertoire of surgical procedures available for osteo-arthritis of the hip-joint.

THE ETIOLOGY AND TREATMENT OF DIABETES:

WITH SPECIAL REFERENCE TO THE SIGNIFICANCE OF A STARCH-
SPLITTING AND ACETONE-FORMING ORGANISM FOUND
IN THE STOOLS OF DIABETIC PATIENTS.

BY

ARNOLD RENSCHAW, M.D. LOND., D.P.H.,

LECTURER IN PATHOLOGY, MANCHESTER UNIVERSITY; BACTERIOLOGIST,
ROYAL EYE HOSPITAL, MANCHESTER; AND HONORARY PATHOLOGIST,
ANCOATS HOSPITAL, MANCHESTER;

AND

THOMAS H. FAIRBROTHER, M.Sc. VICT.

In the consideration of the pathology of diabetes very little is known concerning the source of the acetone bodies—acetone, diacetic acid, and beta oxybutyric acid—which are eliminated from the body in this disease, and which are considered to be the cause of the acidosis and coma which result from their accumulation. The generally accepted view is that these bodies are derived from the amino-acids of the protein molecule, from the fats of the tissues, or even from carbohydrates, but the tendency is rather to explain their origin from the oxybutyric acid derived from fats.

In other words, there is general confusion on this point, and Adams correctly focuses present-day knowledge concerning them when he says, "we cannot as yet say definitely what is the origin of these bodies, whether from the amino-acids of the protein molecule, from the fatty acids, or from the carbohydrates." No one has, so far as is known, laid down any experimental proof that these bodies may be derived from the carbohydrates by bacterial action within the alimentary canal.

Bacteria capable of producing acetone from starch or other carbohydrates have been known to exist for some time; thus in 1905 Schardinger¹ first described such organisms. Secondly, under the name of "Amylobacter," Bredemann² in 1909, described acetone-producing bacteria possessing spores. In this country attention was called to the practical application of these bacteria to industry by Fernbach and Strange³ (Eng. Pat., 1912, No. 21,073), who actually manufactured acetone on the commercial scale by the ferment action produced by those bacteria on starchy foods.

It is known that the acetone production from starch is not restricted to the action of one particular bacterium, but it is very likely that there exists a family of the bacteria which have been described generically as "Amylobacter." The difference between the members of the family is not completely understood yet, but there are distinct differences in size—particularly in the width of the different organisms. Chemically, the point of similarity seems to be acetone production, which is common to all, and the point of difference the nature of the alcohol produced along with the acetone. Thus Fernbach's organism produces acetone and butyl alcohol, and this was developed during the war by Dr. Weizmann on account of the value of these two products, the one as a solvent for gun-cotton, and the latter for its use in connexion with isoprene, an intermediate body in the synthesis of india-rubber. In addition to this there is a complete description in the literature of another organism, *B. aceto-ethylicum*, described by Northrup, Ashe, and Senior.⁴ This organism produces 10 per cent. acetone and 25 per cent. ethyl alcohol and small quantities of propyl and butyl alcohol. It is a much thinner organism than the one described by Fernbach, being only 0.2 to 0.3 μ against 0.8 to 1.0 μ .

A description of the acetone-butyl alcohol fermentation from starch and its technical application is given by Gill⁵ and a description of the organism was published by Thaysen⁶ in

1921. The attention of the authors was drawn to this process in 1919, and the similarity of the products formed by it with those found in diabetes at once suggested to them the possibility of the organism being connected with this disease. Two differences were noted: in diabetes glucose was also present in the urine in addition to the acetone bodies; and in the case of the organism the result of fermentation yielded also butyl alcohol.

It appeared probable, however, that the products of such a fermentation in the alimentary canal by this or a similar organism might upset the glycogenic function of the liver, resulting in the excessive accumulation of glucose in the blood, with a consequent overflow elimination by the kidneys as soon as the blood sugar content became too high. It was further highly probable that the butyl alcohol or other alcohol formed during the course of such a fermentation could be oxidized in the liver so as to avoid elimination as such by the kidneys. This substance might, in fact, be the cause of the pigmentary cirrhosis of the liver sometimes met with in diabetes. It was resolved therefore to examine the stools of diabetic patients for the presence of an acetone-producing organism of the *Amylobacter* group, and attempts were begun in 1919 to isolate such a bacillus and to obtain ultimately a typical acetone fermentation therefrom. At the time these experiments were started very little information was available to the authors regarding methods of cultivating the organism, and successive publications had to be studied to glean a knowledge of the conditions required for a typical fermentation to be carried to a successful completion. The presence of such an organism in the stools of diabetic patients was quickly detected, and this organism produced a certain amount of gas and set up a fermentation in starch media. Films of these cultures showed the presence of a spore-forming bacillus very similar to the organism described as *B. amylobacter* by Ferubach, and described by Gill in 1919. A recent case of diabetes in a very young girl presented a very favourable opportunity for obtaining such organisms in greater numbers than were obtainable in older patients where the disease is of more chronic type.

The results of the present investigations show that in each of five cases we have isolated from the stools of diabetic patients an organism which is capable of producing acetone, *N* butyl alcohol, beta oxybutyric acid, and diacetic acid. The acetone and alcohol are present, as will be seen, in large quantity in good fermentations. Further, an analysis of the stools of these patients has been made and acetone has been recovered from the stools to a certain extent.

In view of the ready absorption of acetone by the blood, the full fermentation yield of acetone cannot be expected in the stool as passed per rectum; but the presence of this substance in the stool, together with the presence of an acetone-producing organism, would point to the alimentary canal as the source of intoxication in diabetes. This fact is significant when it is remembered that the organism flourishes best in carbohydrate media, and that carbohydrate foods are contraindicated in diabetes. The further description can best be considered as follows:

Methods and Media Used.

The following media were used:

Culture Medium A (Semifluid).—Quantities: Ground rice 54 grams, fine oatmeal 6 grams, water to make 1,000 c.cm. The rice and oatmeal are fed slowly into warm water with good stirring. Care should be taken to avoid lumps. Bring to the boil and keep at the boil for a short time to ensure that the starch is gelatinized. Make up to volume and tube out. Sterilize for two hours at 30 lb. pressure.

Alternative Medium (Semifluid).—Quantities: Ground maize 60 grams, made up to 1,000 c.cm. of mash with water. The method of making up is the same as above. The important part is to have the material finely ground and to see that the mash is otherwise sterilization is difficult. For press may be made with a 4 or 5 per cent. way.

Culture Medium B (Solid).—First make up 1,000 c.cm. wort. Mash 100 grams of finely ground maize (or 99 grams of ground rice and 10 grams of oatmeal) with water to make up 1,000 c.cm. After boiling for fifteen minutes cool to 60° C. Add 10 grams of ground malt and keep at 60° C. for one hour, stirring all the time. Then bring to the boil for fifteen minutes to kill the diastase. To this add 10 grams of gelatin, 10 grams of calcium carbonate, and 50 grams of agar. Heat gently to bring these into solution, then filter. Tube out and sterilize for one hour at 15 lb. pressure.

Method of Isolation.

The stool from the patient is emulsified with sterile water or saline. If two or three days old this emulsion will contain spores,

and it can be pasteurized for fifteen minutes at 75° C. before inoculating into Medium A. If fresh, it is preferable to inoculate direct without pasteurizing. In any case heavy inoculations of the stool should be made by means of a sterile pipette to the bottom of the tube one to three medium should beco Spores will now have formed, and "pasteurization" may be carried out for ten to twenty minutes, at 75° to 80° C., when portions of the culture are diluted in sterile saline. It is preferable now to mix them in culture Medium B so as to isolate separate colonies. This medium should be melted and then cooled to 42° C. before admixture of the diluted pasteurized growth from the previous incubation, the medium being poured before solidification into sterile glass tubes 6 by 1 fitted at each end with sterile rubber stoppers. (These tubes should have been plugged with wool at each end and sterilized, the stoppers having been autoclaved.)

When solidified the inoculated tubes are incubated until growth occurs and the medium is split by the gas formation, which occurs round the colonies of the acetone-producing organisms or other bacteria. The tube is then uncorked at one end, warmed to allow the solid medium to slide out into sterile Petri dishes, and then cut up into slices, scrapings obtained from the different colonies being inoculated into tubes of Medium A. These tubes should now contain the organism in pure culture, and further fermentation should proceed at a more rapid rate. In view, however, of the small amount of inoculum obtained from the scrapings two days may elapse before even slight fermentation is visible; but when once established the culture should be pasteurized and inoculated heavily into several tubes. Two or three tubes at least of an actively growing culture obtained as above should be then inoculated into a warm flask of the starch medium containing one litre of 6 per cent. mash. (Approximately 50 c.cm. of actively growing inoculum are required for one litre of mash.)

The flasks should be incubated until fermentation is completed, usually thirty-six to forty-eight hours being required in a good fermentation. The contents of the flask are then distilled and the distillate examined quantitatively for acetone and butyl alcohol, and qualitatively for diacetic and oxybutyric acids. The presence of a good fermentation is represented visibly by the evolution of a considerable amount of gas, which consists of CO₂ and H₂. This may be so vigorous that the plugs of the tubes or flasks, if caked with inspissated mash, may be blown out. Meanwhile, the starch is being split up by the diastatic ferment liberated by the growth of the bacillus, and a clear watery fluid forms in which masses of partially-digested starch may be carried up to the surface, there to form a head in the tube or flask. This head later sinks and a clear supernatant watery fluid remains.

In the above method, if it is desired to dispense with the solid medium in the anaerobic tube, the only other method available is to take a number of tubes containing high dilutions of the bacteria and to attempt, by repeated pasteurization, incubation, and dilution, to obtain the organism in pure culture.

It cannot be too clearly indicated, however, that there are numerous impurities which will prevent the fermentation from being carried out, and the only way in which good fermentations can be obtained is apparently by the simultaneous growth in masses of large numbers of the organisms. Reference will be made to these impurities later in regard to treatment. It is probably only on account of the presence of other bacterial impurities in the food within the alimentary canal that diabetes is not a more rapidly fatal disease—these impurities lowering the yield of acetone bodies which would otherwise be formed. Further, the great difficulty of carrying through a fermentation *in vitro* from such highly infected material as faeces cannot be too clearly indicated.

Description of Organism.

The organism isolated is a Gram-positive rod-shaped bacillus and is a facultative spore-forming anaerobe. The bacillus is usually straight, 4 to 6 μ in length, and about 0.9 to 1.2 μ in thickness. The ends are slightly rounded. It may occur singly or in chains of two to six organisms, or the forms may lie parallel, two or three parallel forms being fairly common, and parallel forms may be present even when the members are existing in chain formation. It is possible that this may represent fission in two planes—longitudinal and transverse. Young cultures are slightly motile, and in forms more than twenty-four hours old central spores may develop. The spores are oval in shape, protrude beyond the width of the bacillus, do not take the Gram stain, and usually have a small vestige of bacillary protoplasm left at each end. This vestige tends ultimately to disappear in older spores. The bacilli take basic stains, being well stained by carbol fuchsin (1 in 10), and less definitely stained by methylene-blue. The Gram staining in young forms is quite definite. We suggest that the term *Bacillus amyloclasticus intestinalis* be applied to the organism as found in the intestine of man.

Result of Fermentations.

By the activity of the organisms proteolytic and diastatic enzymes are liberated. The diastatic enzyme, by its action, splits up starch; the proteolytic enzyme is manifest by the slight liquefaction of gelatin which occurs round the site of the colonies produced in Medium B. The organism develops best under anaerobic or partially anaerobic conditions, these conditions being satisfied when cultures are inoculated to the bottom of the tubes or flasks containing a well-gelatinized mash. In order to obtain an active fermentation of starch it appears necessary for a liberal amount of inoculum to be added (up to 5 per cent. of the tube or flask to be inoculated), since the fermentation appears to be retarded and even suppressed unless a large mass of organisms is growing simultaneously in one part of the medium. It is not, therefore, a good method to disseminate too freely the inoculum added.

The bacilli require a small quantity of protein with their starch, but experiments in hand appear to show that peptone can be substituted for protein, although it was at one time considered that peptone would not suffice. (See also *Journ. Biol. Chem.*, 1919, 39, 1-21.)

If the reaction of the mass is taken in which fermentation is actively proceeding it is found to rise rapidly, ultimately alling on completion as follows:

1. Before incubation 10 c.cm. of mash required 0.3 c.cm. N/10 NaOH to neutralize.
2. After twenty-four hours 10 c.cm. of mash required 3.96 c.cm. N/10 NaOH to neutralize.
3. After forty-two hours 10 c.cm. of mash required 2 c.cm. N/10 NaOH to neutralize.

In addition there is a considerable evolution of gas, which is found to consist of hydrogen and CO₂. The estimation of the acidity can be regarded as indication of the progress of fermentation.

Examination of Products of Fermentation.

The signs of completed fermentation are cessation of gas evolution, and no further fall in the acidity of the liquor. The final acidity in a normal fermentation is such that 10 c.cm. of the mash require 1.8 to 2.5 c.cm. of N/10 NaOH for neutralization. (Boil off dissolved CO₂ before testing the acidity, and use phenolphthalein as an indicator.) The mixture of acetone and alcohols is referred to as mixed oil, and the estimation is carried out as follows:

The plug of the flask is removed and replaced by a stopper carrying a tube to a condenser, and the mash is distilled until no further oily drops are noticed in the condenser. Usually this distillate is 10 to 15 per cent. of the total volume in the first flask. The distillate is saturated with common salt and redistilled until no further oily drops are noticed.

The second distillate is saturated with anhydrous potassium carbonate and poured into a measuring cylinder. The potassium carbonate solution settles to the bottom, and there is a very definite dividing line between this and the layer of oil. The volume of mixed oil obtained is read off on the cylinder. (If preferred, it may be separated in a separating funnel and weighed in a closed bottle.)

For estimation of the acetone in the mixed oil, the latter must be diluted to a suitable strength. If 25 c.cm. of iodine are used in the iodoform estimation the amount taken should contain about 0.01 gram acetone. For example, if the mixed oil contains approximately one-third its weight of acetone, 10 c.cm. are taken and made up to 100 c.cm. Then 10 c.cm. of this dilution are taken and made up to 250 c.cm., and 10 c.cm. of this last dilution will contain approximately 0.01 gram of acetone, and it is the amount used or titrated.

Take 10 c.cm. of this diluted liquor, add 25 c.cm. N/10 iodine solution and 6 c.cm. of 20 per cent. NaOH solution; allow to stand for five minutes, then add 6 c.cm. of 20 per cent. HCl and titrate the liberated iodine with sodium thiosulphate (N/10). This gives the amount of iodine not used in the making of iodoform from the acetone, so that the difference between 25 c.cm. and this figure is the amount of iodine used; 1 c.cm. of N/10 iodine is equivalent to 0.000967 gram acetone.

Results of Case Examination.

The results obtained in cases in which fermentation was carried to completion were as follows:

Urine Examination.

Patient.	Sugar (Grams per Litre).	Diacetic Acid.	Acetone (Grams per Litre).
Ma. ...	45.4 "	Present	0.72 gram.
Ho. ...	40.5 "	Present	0.047 "
Wa. ...	20.0 "	Large amount	0.057 "
Ba. ...	42.7 "	Present	0.70 "
Br. ...	30.0 "	Present	0.25 "

Stool Examination.

Patient.	Acetone in Stool as Percentage on Dry Stool.	General Remarks as to Bacteriology, etc.
Ma.	0.05 per cent.	B. amyloclasticus intestinalis present; also a long, thick bacillus from which it had to be freed by repeated pasteurization and sub-culturing.
Ho.	0.043 per cent. with in addition acetone bodies equivalent to 0.02 per cent. crotonic acid	B. amyloclasticus intestinalis found.
Wa.	Not examined	B. amyloclasticus intestinalis found.
Ba.	0.036 per cent.	B. amyloclasticus intestinalis.
Br.	0.08 per cent.	B. amyloclasticus intestinalis.

Fermentation on Starch Media by Organism Isolated from Stool in each Case.

Final acidity of mash being approximately 2 c.cm. N/10 NaOH to neutralize 10 c.cm. in each case.

Patient.	Mixed Oil Products.	Percentage Weight of Acetone on Starch.	Nature of Oils.
Ma.	20 c.cm. on 55 gm. starch and 5 gm. oatmeal	9.2	N butyl alcohol equivalent to twice amount of acetone present.
Ho.	17.2 c.cm. on 54 gm. starch and 6 gm. oatmeal	6.8	Diacetic acid and N butyl alcohol present. Trace of iso-butyl alcohol.
Wa.	9 c.cm. on 25 gm. starch and oatmeal	6.6	Acetone and N butyl alcohol.
Ba.	13 c.cm. on 50 gm. rice and 5 gm. oatmeal	5.8	N butyl alcohol and acetone.
Br.	10 c.cm. on 27 gm. rice and 3 gm. oatmeal	5.2	Acetone; N butyl alcohol; trace iso-butyl alcohol.

The alcohols were identified by preparing the 3,5 dinitro-benzoyl esters and examination of the same.

Altogether nine cases of alleged diabetes have been under examination. Of these, five have been completed, and the results are indicated in the tables. The remaining four are receiving further experimental work. The organism has been detected microscopically in two of the remaining cases, but with it foreign organisms, which have retarded its action in the complete massive fermentation of starch, and great difficulties have been met with in obtaining the organism in pure culture.* There is sufficient indication that in a short time these difficulties will be overcome and that the experimental results can be added to the five reported cases. Of the other two, one shows glycosuria following emotional disturbances, and the other is a young child now rendered sugar-free. As controls, eleven non-diabetic stools have been examined, and the organism has not been detected in any case.

Occurrence of Similar Organisms in Nature.

The acetone bacillus which was used during the war was believed to occur on decaying maize, on bad potatoes, and on other decaying vegetable matter. Northup isolated *B. aceto-ethylicum* from bad potatoes. Jute retting is supposed to be due to a similar organism, and in this respect the incidence of diabetes in Dundee amongst jute workers is highly suggestive of a bacterial infection by our bacillus. Occurring as it does on decaying vegetable life it is easy to understand how such a heat-resistant, spore-forming organism should enter the alimentary canal of human beings. It is probable that, if this be so, one of the post-war effects will be a considerable increase in the incidence of diabetes and of acidosis.

Discussion of Results with a View to Treatment.

The degradation of the complex starch molecule probably occurs by the formation of fatty acids with large molecules and then successive oxidation of two carbon atoms at a time, starting in the beta carbon atom. Ultimately, through the stage of intermediate fatty acids, the four-carbon fatty acid (butyric acid) will be arrived at. Oxidation will proceed normally at the beta carbon atom, producing the beta oxybutyric acid; this is capable of further oxidation at the same point to aceto-acetic acid, and this will be ultimately broken up, giving acetone and CO₂. The changes can be followed by means of the following formulæ:

* Since this article was prepared for press one of the two has given typical fermentations.

Thus it would appear that the beta oxybutyric acid and the aceto-acetic acid produced in the course of the disease are intermediate products leading ultimately to acetone, providing the conditions are favourable. This conclusion is supported by the observations on the fermentation, where it is noted that the end of the reaction is determined by the fall in the acidity of the mash.

The fact that the alcohols produced in the fermentation are not detected in the excreta of diabetic patients can be explained to some extent by their absorption and possible oxidation in the liver to products which would not be easily detected. Stepp¹ claims that he has detected aldehydes (or substances which react in every way like aldehydes) in the blood of diabetic patients. Aldehydes would be the first products of the oxidation of normal alcohols, and complete oxidation would lead to CO₂ and water. In endeavouring to obtain good yields of acetone the inhibitory effects of certain bacteria came to be recognized. Thus Thaysen states that the organism which causes most damage to a fermentation is the *B. volutans*. Others have described the *B. acidilactici*, and we have found the presence of a diplococcus and of a large thick bacillus, of unknown identity as yet, to be responsible for much inhibition. It appears probable that these facts, combined with a diet so composed as to allow digestion and absorption by the patient of foods which the bacteria cannot assimilate, will prove an important part of treatment, combined with the administration of certain antiseptics. In this respect the authors² would call attention to their work on the subject of antiseptic action amongst the coal-tar dyes, which gives useful data as to the relative value of dyes as antiseptics in regard to different organisms.

SUMMARY.

1. From the stools of diabetics a new organism (*B. amyloclasticus intestinalis*) has been isolated which splits up starchy foods, forming oxybutyric acid, diacetic acid, butyl alcohol, and acetone. Sugar is also formed during this fermentation.

2. Acetone has been found in quantities capable of estimation in the stools of diabetics.

3. In diabetes carbohydrate fermentation occurs in the alimentary canal, forming abnormal products which probably so affect the glycogenic function of the liver as to lead to the glucose from the alimentary

4. Definite lines of treatment include elimination or suppression of this organism.

We wish to express our indebtedness for access to diabetic cases to Dr. J. Gray Clegg, Dr. Wm. Stirling, and Dr. Langley; and to Mr. A. Gill, B.Sc., for his technical assistance with the various processes herein detailed.

FRAGILITAS OSSIUM ASSOCIATED WITH BLUE SCLEROTICS IN FOUR GENERATIONS.

BY

J. BROWNING ALEXANDER, M.D., M.R.C.P. LOND.,

PHYSICIAN WITH CHARGE OF OUT-PATIENTS, PRINCE OF WALES'S GENERAL HOSPITAL, AND CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

Instances of fragilitas ossium associated with blue sclerotics have from time to time appeared in medical literature, and as recently as December 24th, 1921, Blegard and Haxthausen of Copenhagen reported in the *BRITISH MEDICAL JOURNAL* cases showing, not only blue sclerotics and brittle bones, but also associated with macular atrophy of the skin and zonular cataract. Such cases are, however, sufficiently rare to warrant putting on record the following history:

The patient, F.F., aged 71 years, presented himself at my out-patient department about a year ago. The history was that he suffered from repeated fractures—the most recent having been one of the lower end of the right tibia. Some deformity was present in the right leg and the right thigh, and it was ascertained that both the tibia and the femur had been previously fractured—the latter having occurred at birth. In addition a history was obtained of past fractures of the left humerus and the tibia and fibula of the left leg. These had healed with apparent perfect union and minimal

amount of callus. The most striking feature which one observed when the boy entered the consulting room was the marked blueness of both sclerotics. The child was somewhat pale and debilitated, the forehead more prominent than normal, but no evidence of rickets was apparent. In other respects the mother stated that the boy had always been healthy. The mother, to whom the boy bore a strong resemblance, showed very deep blue sclerotics. She had, however, no fractures. Her hearing was defective, and she informed me that she had suffered from deafness for many years. The patient's two sisters, whom I saw later, also presented blue sclerotics, with, however, no history of fractures. On inquiring further into the history of the family I found that the aunt of the patient (the patient's mother's sister) had sustained altogether seven fractures during her life and had, as in the other members of the family, deep blue sclerotics. The grandmother and great-grandmother had both been the subjects of fragile bones and blue sclerotics. No further history of these phenomena was forthcoming in previous generations to the ones already mentioned; it is quite possible, however, that a careful study of this family's genealogy would have revealed the same condition in former generations.

This remarkable association of brittle bones and blue sclerotics was first described by Eddowes in 1900, who suggested that "the transparency of the sclerotics indicated a want of quantity or quality of fibrous tissue forming the framework of the various organs of the body, and probably explained the want of spring or toughness in the bones of these individuals." The importance of heredity in these cases was most clearly indicated by Stephenson and Harman in 1910, who published accounts of the same family of blue sclerotics—together 55 individuals in five generations, 31 of whom showed typical sclerotics. No mention was then made of fragile bones; but in 1915 Stephenson showed at the London Ophthalmological Society a mother and two daughters with fractures, belonging to this family. Rolleston, in 1911, reported 4 cases of blue sclerotics in three generations, with fragile bones occurring only in the third generation. Peters, in 1903, published the account of blue sclerotics in a family during three generations, and five years later further reported the occurrence of fractures in these cases. The interesting case reported by Ostheimer in the *Journal of the American Medical Association* of December, 1914, had blue sclerotics and nine fractures between the ages of 1½ and 4 years. In this case there was no history of the condition occurring in other members of the family. The literature of the subject is further enhanced by the publication of similar cases by Burrows, in 1911 (a family of 29 individuals—13 with blue sclerotics, and 9 of the 13 with brittle bones); Poynton, in 1913 (1 case); Hoffmann, in 1915 (3 cases); E. Bronson, in 1917 (description of two families); and Olaf Blegard and Holger Haxthausen, *BRITISH MEDICAL JOURNAL*, December 24th, 1921.

There seems to be little doubt that the blueness of the sclerotics is due to the increased transmission of the colour of the choroidal pigment and not to any inherent colouring of the sclerotics themselves. Some think, however, that there is an actual thinning of the sclerotics. Fridenberg has suggested that the blue sclerotics are due to a transparency depending upon the absence of lime salts in the connective tissue of the sclera. The long-standing deafness in the case of the mother described is worthy of notice, and might possibly be explained, as Brooson suggested, by a deposition of calcium salts in the middle ear, relating to the abnormal osteogenic process.

THE RECOGNITION AND TREATMENT OF MINOR DEGREES OF FIBROSITIS.

BY

THOMAS MARLIN, M.D., D.P.H., D.M.R.E.,

ASSISTANT ELECTRO- AND PHYSIO-THERAPEUTIST TO THE MIDDLESEX HOSPITAL.

Knowing the danger of missing an internal lesion which may be associated with superficial pain we naturally in such cases look for some objective sign. Failure to realize that the cause of many pains can be definitely detected in the soft tissues may explain why their examination is neglected. A patient who complains of pain in the region of the right scapula may be taken as an example. There may be some tenderness on pressure over a particular area, but otherwise nothing definite is noted; there is no swelling, no grating in the joints, and the lungs and heart are normal. The teeth may be surveyed and search made for some source of infection or irritation, without finding anything to confirm the patient's statement. If, however, we now devote a little

OSTEITIS DEFORMANS.

678 APRIL 29, 1922]

more time to the soft tissues where the pain appears to be, comparing if necessary with the other side, we may note some resistance in a part of the muscle, and the patient will tell us we are exactly on the offending spot; on continuing the examination we may presently discover that the resistance is due to a definite fibrous thickening. Further useful information may be obtained by working from the patient's point of view. When we palpate the tissues and try to define the indurations, we are carrying out the ideal massage for this condition, and the sufferer will know at once that to continue those manipulations would do good. In this we have the key to the treatment—namely, massage, which is not merely superficial rubbing, but is really a repetition of the manipulations carried out during our examination. Changes can actually be felt to take place in the fibrous tissue under the influence of massage.

The foregoing is typical of the easily recognized condition of fibrositis as seen in muscular rheumatism; more obscure cases may be due to minor degrees of fibrositis which may be difficult to diagnose. Time and patience are necessary, but frank co-operation with the patient will tell us if we are on the right track. The following case is instructive:

A lady, aged 34, had had a fall on the coccyx fifteen years previously, and had since suffered pain round the coccyx and right side of sacrum. The pain was of a vague character, generally gave rise in distribution, and, though not always acute, generally gave rise to some feeling of discomfort. Latterly she had become very irritable and a worry to her relatives. The pelvic organs were declared healthy, and a small anal fissure had been operated on, but as no benefit resulted from this further consultations were held. Apparently the advisability of the removal of the coccyx was discussed, though it was pointed out that there might be a large mental element present, as the patient was considered highly neurotic. Had it been possible to guarantee cure, the patient would gladly have undergone the operation, but at this stage she consulted me. The painful area was gently palpated for evidence of fibrositis, yet, even before I had time to make up my mind, the patient exclaimed, "Do you know, I have been waiting for years for someone just to do that to me." This remark was very significant. She had done all she could to obtain relief, had offered herself for examination and treatment by different medical men, and on every occasion had tried to direct attention to the actual seat of pain. Casual examination had shown nothing to account for it, and the search had been carried farther afield without success.

As the examination proceeded the tissues soon relaxed sufficiently to allow certain definite painful fibrous strands to be felt. My mind was now fully made up that here was a case of fibrositis with every reasonable prospect of clearing up. The treatment, which consisted of massage and diathermy, was attended by improvement, and after thirteen visits the patient was quite free from pain. There has been no return of any discomfort since she was last seen over twelve months ago.

It will be observed that we may easily be misled unless we keep before us the possibility of fibrositis. A person with pain in the left side of the chest may have a systolic murmur at the apex, yet the origin of his complaint be entirely in the intercostal muscles. Similarly, people may have pain in the loins arising from the muscles in the back and quite unconnected with the kidneys, even though the urine might show a trace of albumin. In the case just quoted the anal fissure was not to blame, yet had some pelvic disorder been present our minds would have turned to that as the causative agent.

In certain other conditions the cause may be found in a region unsuspected by the patient. Headache is often due to indurations in the upper fibres of the trapezius, and relief quickly follows appropriate treatment of these areas. In several cases of flatulent dyspepsia the condition has been speedily cured by treatment directed to fibrous nodules or strands in the erector spinae muscles.

In one instance a lady who for several months had had headache and sickness, with actual vomiting after dinner, was seen one afternoon during an attack of headache; this disappeared after about ten minutes' massage to the back of the neck, and there was no sickness that evening—the first time for months. Further examination revealed indurations in the erector spinae muscles. These disappeared after massage, and she has now been quite well for over nine months.

The simple headaches may be due to spasm or cramp of the scalp muscles induced by the pathological condition in the trapezii, and the relief can thus be explained; but I hesitate to advance any definite theory as to the disappearance of the dyspepsia. We know, however, that if one muscle or set of muscles is painful on contraction the antagonistic muscles, which do not merely relax but rather pay out, will be awkward in their movement, being more or less on tension all the time to avoid or limit jarring of the painful muscles. If, then, there is trouble in the erector spinae muscles the

abdominal muscles will be correspondingly affected, and thus may react on the normal digestion processes.

The possibility of eye-strain and other sources of irritation or infection must of course be borne in mind, and as superficial pain may be due to, or an accompaniment of, deep-seated lesions, masseurs must have some guide to help them. This they may obtain from the patient. A patient with reflex spasm in the abdominal muscles set up by an inflamed appendix or an enlarged spleen draws away from the examining hand. On the contrary, the person with fibrositis feels at once that the manipulations are going to the seat of his trouble, and asks for prolongation of the treatment as it is so comforting. This guide eliminates the chance of doing damage in obscure cases, and has also enabled me at different times to attack confidently various pains associated with definite organic disease, but which nevertheless appeared to be due in part to local conditions. To quote two examples:

A man consulted me with regard to pains shooting from the back beneath the ribs, round towards the front of the body. I came to the conclusion that he had hereditary syphilis, and refused to treat him until he had submitted to examination and treatment by someone else. When he had started on a course of salvarsan I treated his back, with much benefit.

The other case, a lady, aged 22, who had definite evidence of intra-cranial pressure, asked me to treat her for violent headaches. I specifically warned the mother that at the most we were only dealing with a symptom, and no matter how much improvement might ensue, she must be prepared to go on with the operative measures which had been arranged to take place later. Massage to the trapezii, which were tight and contracted, gave such pronounced relief that, in spite of my previous warning, the mother began to doubt the diagnosis already made, and only with difficulty was she persuaded that trephining was still necessary.

A CASE OF OSTEITIS DEFORMANS
(PAGET'S DISEASE).

BY

J. LINDSAY, M.D., M.R.C.P.,

PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH;
AND

R. G. GORDON, M.D., M.R.C.P.Ed.,

PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH.

Cases of Paget's disease are of sufficient rarity to make it desirable to put on record such a striking case as the present one.

W., aged 54, was always well in childhood, and at the age of 22 joined the army. He served for nineteen years, fourteen of which were spent in South Africa, Egypt, India, and Burma. He only went sick six times during his service; he had malaria three times, twice in India and once in Burma, with one month's sick leave each time. He had dengue fever in Madras and influenza twice. At the outbreak of war he volunteered for service and was sent to Canada on special work. He spent five years in the service and never missed a day's duty for sickness. He has suffered from piles and a certain amount of constipation ever since he was 30 years of age.

Family History.—His mother died of Bright's disease at an advanced age. His father died at the age of 88 after suffering considerably from arthritis in both hips. Two paternal uncles also suffered very much from the same trouble.

History of Present Illness.—The first time he ever noticed any trouble with his locomotor system was after a bad attack of sciatica in Burma fifteen years ago. He was coming down the river a distance of 1,000 miles, returning to Rangoon, and the sciatica came on five days after leaving his station. He was never quite the same since this attack, but there was no serious trouble until 1915, and even then the stiffness did not trouble him to any great extent. In January, 1915, he was in Halifax and got worse every year, having very bad colds. Six months after the armistice he applied for a medical board and was sent to Harrogate. In the winter he had chronic nasal catarrh, which left him deaf. In 1918 he began to notice enlargement of his bones, and finally had to have these made for him as nothing was kept in stock which would fit him. He had for the last four or five years suffered from a good deal of pain and stiffness in the left hip, which had been relieved temporarily by ionization, otherwise he had suffered no pain. There was no history of trauma at any time that he could remember.

The patient appeared in very fair general health, but the enlargement of the head gave him a peculiar aspect. He walked slowly and stiffly, owing to limitation of movement in the left hip, and required the help of a stick, but at his own pace could cover up to half a mile without undue fatigue. The following bones were found to be affected by the osteitis: The whole of the cranium was markedly enlarged, with considerable outgrowth of the frontal bones. The facial bones were practically unaffected. The cervical vertebrae were not noticeably enlarged, but there was a good deal of osteitis in the lower dorsal region. The ribs were not affected. The lumbar vertebrae were not involved to the extent of the dorsal.

The ilia were considerably enlarged. The right shoulder girdle was only very slightly affected. The right humerus was markedly affected in the head and lower part of the shaft. The upper third of the right ulna and whole of the right radius were involved, the arm showing considerable bowing. The small bones of the right wrist and hand were not affected in any way. The left shoulder girdle, clavicle, and coracoid were slightly involved; the head of the left humerus and the shaft scarcely at all. The olecranon process and head of the left ulna were involved, but the rest of the bone and the radius had almost entirely escaped. The small bones of the wrist and hand were normal. The head of the right femur was involved to a certain extent, as was the shaft, and the ischium was slightly affected. The lower end of the right femur was markedly affected, as were the tibia and fibula, the leg showing decided bowing. The left pubis ischium and femur were very markedly affected, and there was a decided superimposed arthritis in the left hip-joint. The tibia was very markedly affected and the fibula to a less degree, the knee-joint showing a mild arthritis. Small bones of the ankle and foot were not affected, nor were the lower portions of the tibia. The articular surfaces were, on the whole, free, except for the left hip and left knee. These were painful on extreme movement in any direction, but more particularly in abduction and external rotation of the hip.

Examination of the heart and lungs was negative. No abnormalities were found in the abdomen, with the exception of slight piles both external and internal. This did not trouble him to any great extent except for slight bleeding about once in six weeks. The teeth, though many had had fillings, were healthy and the gums showed no pyorrhoea. Mr. Mumford kindly examined the nose and throat, and reported as follows: A chronic post-nasal catarrh with chronic pharyngitis. Pus was exuding from the antrum in considerable quantities. He did not advise operation, as in the porous condition of the skull bones infection might be spread farther. The tonsils were comparatively healthy. Blood examination showed no abnormalities, and the urine examination was negative. The Wassermann reaction in the blood was negative. The diet had been so varied, owing to his residence in India, Canada, and England, that no conclusions could be drawn.

Treatment.—He was given ionization to the left hip, as this had given him relief before, and he was instructed in the use of nasal antiseptics. After four weeks the pain in the hip was somewhat relieved, but otherwise he remained in *status quo*.

This case seems to correspond exactly to the original clinical picture described by Paget. There is no obvious cause for the onset of the inflammation, it being noticeable that there is no history of trauma. Certain observers have lately suggested that Paget's disease occurs after blows on the various parts of the skeleton. It would seem, however, that the conditions are definitely distinguishable, and Paget's disease cannot be classed with the cases of traumatic osteitis. The course of this disease is slow and does not affect the general health to any extent. In the present case there was little or no pain except in the left hip and knee, which would seem to be due more to superimposed arthritis than to the actual inflammation of the bones. Pain is not always absent in Paget's disease, as in some cases tender points have been described frequently on the tibia and sometimes in the skull. The progressive enlargement of the vault of the skull is exceedingly characteristic, and the x rays at once puts the diagnosis beyond doubt. So far no treatment has been discovered which holds out any prospect of relief. In the cases of traumatic osteitis referred to above Lano seems to have had some success by scraping out cancellated parts of the bone, but in such a widespread condition as the present this treatment is obviously inapplicable.

"PERNICIOUS ANAEMIA," APLASTIC OR TOXIC.

BY

J. F. REY, M.R.C.S., L.R.C.P.,

ROGNOR.

AN interesting case of "pernicious anaemia" recently came under my care. The patient was an Englishman, aged 48, who had a splendid health record; he weathered the strenuous South African campaign, suffering great privation and exposure, and remained physically fit and worked hard afterwards, but eventually in 1917 his "nerves gave way" owing to privations, business worries, and bad food. His weight decreased; haemorrhoids, from which he had suffered for twenty years, caused trouble, and were removed by operation in March, 1918. Nine months later bleeding and discharge began to occur at intervals every few weeks. In 1919 his appetite became poor, and he felt languid, depressed, and fatigued; flatulence was marked, and his colour became pale. In November, 1920, he had "influenzal catarrh" with diarrhoea lasting fourteen days; an anal abscess developed and burst, leaving an anal fistula. This was successfully cured, under cocaine anaesthesia, during his present treatment.

The blood picture of the aplastic type of pernicious anaemia, as given by H. Vasquez and Ch. Aubertin in *Le Traitement des Anémies*, is as follows:

No poikilocytosis, no anisocytosis, no polychromatophilia, decreased number of leucocytes, relative decrease of polymorphonuclears; no myelocytes; no eosinophils; no nucleated reds, no haematoblasts. Congulation absent or greatly decreased.

Now the first blood picture of the case here related conformed to this type in all particulars except the anisocytosis; only a few large red cells were found. The relative number of mononuclears throughout the course of the disease was excessive and this pointed to the existence of a bacillary infection which was not overcome. I was led, therefore, to believe that I was dealing with a case of toxic anaemia.

	Jan. 27, 1921.	Feb. 23, 1921.	April 21, 1921.	July 4, 1921.
Red cells	2,800,000	2,500,000	5,300,000	6,800,000
Haemoglobin (Haldane's) ...	42%	65%	93%	105%
Colour index	0.9	0.77	0.8	0.8
Leucocytes	6,542	7,500	8,125	8,417
Polymorphs	62.4%	24.5%	50.6%	49%
Mononuclears	33.2%	64.7%	43.4%	46%
.. large	5.6%	43.2%	35%	2%
.. small	27.9%	21.5%	8.4%	19%
Eosinophils	Nil	3.1%	1%	1%
Mast cells	0.9%	Nil	Nil	Nil
Eichhorst's corpuscles ...	Nil	Nil	1 in 1,000 reds	2% reds
Abnormal cells	A few large red cells	None	None	None
Arnett's index (normal 2.76)	2.91	4.05	2.23	2.55

The diarrhoea was first checked by astringents and tincture of opium. Gastritis was troublesome until the discovery that there was a lack of free hydrochloric acid in the gastric contents. The administration of hydrochloric acid in large quantities overcame this and stopped the excessive flatulence which he had after meals. Carbohydrates were restricted; later he gradually took to normal diet. Injections of soamin were given until the maximum amount was injected. Capsules of beta naphthol (1½ grams) were given daily and also haemoglobin.

When I saw the patient on July 4th, 1921, he appeared in excellent health, eating well of everything, sleeping well, enjoying all sports, and complaining of no fatigue. In this condition he returned to South Africa to resume his former work. On October 1st, 1921, all medicine was discontinued. In a note dated February 15th, 1922, he states that he is "absolutely fit in every way."

THE LOCAL APPLICATION OF TUBERCULIN.

BY

JAMES CROCKET, M.D., D.P.H., M.R.C.P.,

LECTURER ON TUBERCULOSIS, GLASGOW UNIVERSITY; MEDICAL
SUPERINTENDENT, CONSUMPTION SANATORIA OF
SCO. LAND, BRIDGE OF WEIR.

MODERN writers on tuberculosis tend to decry the value of tuberculin. Fowler, in his recent volume on tuberculosis, says that "nothing at all is heard now of tuberculin as a remedy." It does not, however, follow from this that it is not being used to good purpose. While not a specific for tuberculosis of the lungs, it is, if given in small doses at weekly intervals, undoubtedly an influential factor for good. Cases treated with tuberculin make more satisfactory and more rapid progress than others not receiving such injections. In addition to using tuberculin hypodermically in pulmonary tuberculosis, we have for several years been using it locally—in gland cases, in lupus, and in abdominal tuberculosis particularly—with excellent results.

The tuberculin is made up in an ointment, using anhydrous lanoline as a basis when lupus or adenitis is treated. It is made up in the form of a liniment when dealing with abdominal disease or pulmonary tuberculosis. The strength of the preparation varies according to the reactive power of the patient; the aim being to secure a definite reaction at the site

into which it is rubbed, the reaction being indicated by a roughening, a reddening, or a papular eruption on the skin. The ointment or liniment should not be strong enough to produce a general reaction, as indicated by an increase of temperature, anorexia, or malaise. No case dealt with by us along the lines mentioned has ever shown such a reaction. Koch's old tuberculin T. or P.T., or preferably equal parts of both, is used. We generally make up the ointment in four strengths—namely, No. 4, 1 in 4; No. 3, 1 in 3; No. 2, 1 in 2; No. 1, 1 in 1. In dealing with glands, for example, we begin with the weakest ointment, No. 4, one part of tuberculin to four of anhydrous lanoline, rubbing in a piece the size of a pea. If there be a reaction, we keep on with that, applying a similar amount every five days. If there be no reaction, we go on to the stronger form. In some cases we have to use the strongest form—namely, equal parts of tuberculin and anhydrous lanoline—before a satisfactory reaction and result are obtained. If, on the other hand, the reaction be very severe from using the weakest of the four strengths, the 1 in 4, it is necessary to use a still weaker preparation. In several instances we have had to use it as weak as one part of tuberculin to eight parts of anhydrous lanoline.

A diminution of the size of the glands is usually noted within a week or two. It may take several months to cause them to disappear. Treatment of glands by operation produces more rapid results in gland cases, it is true. On the other hand, recrudescence of the disease is very common after operation; further, dissemination of the disease not infrequently ensues in such cases, and at the best there is the tell-tale disfiguring scar. When dealt with by tuberculin the cure results along nature's own lines by the production of antibodies and by raising the resistance of the individual. Four cases may be quoted.

1. A carter, aged 46, was admitted to the sanatorium with two large masses on either side of the neck. Treatment with tuberculin locally resulted in those masses, which in one instance were as large as a closed fist, becoming scarcely palpable. Treatment lasted for five months.

2. This patient was seen at the dispensary in Glasgow. Her mother was a patient in the sanatorium suffering from pulmonary tuberculosis, spinal disease, and tuberculosis of the knee. The patient herself had been operated on, she did not know how often, for glands of the neck. There were several discharging scars reaching almost from one ear to the other. Numerous glands, varying in size, were palpable on both sides of the neck, and above the right clavicle there was an irregular mass about three inches broad. She told us that she had received instructions to go into a Glasgow hospital to have a further operation. We asked the Glasgow Corporation to send her to us, in order that we might try conservative measures. The injection of tuberculin has resulted in a total disappearance of the glands on both sides of the neck. The patient has increased in weight. All toxic symptoms, which previously were very marked, have disappeared.

3. A woman was admitted to the sanatorium with very large masses of glands well down both sides of the neck; she also had involvement of the lungs. There was infiltration to the level of the fourth rib on the left side, and to the second rib on the right. We gave her tuberculin injections immediately on admission, using 1 in 3 ointment. An improvement was noted within a fortnight. After a month we went on to 1 in 2 ointment, and kept on that for four months, applying it twice each week. At the end of that period we used 1 in 1. She was able to stand the stronger ointment without excessive reaction. We discharged her from the sanatorium after six and a half months. The glands were not palpable, and the lung disease perfectly quiescent.

4. A young lady, aged 20, was admitted with a scattered mass of glands reaching from the mastoid process to the clavicle on the right side. They were matted together and adherent to the skin, and there was no ulceration, the condition was very disfiguring. Tuberculin was applied by injections, and all traces of the glands were removed within six months.

These cases, selected at random, illustrate the results very generally obtained. In treating glands other measures may of course be required. For example, when there is caseation the caseous matter must be aspirated from time to time. When there is associated scrofuloderma the ulcerating areas must be cleaned, and may require to be touched up with acid nitrate of mercury or pure lysol to accelerate healing. When there are discharging sinuses the injection of Calot's oil or paste or of bipp facilitates their closure. Ultra-violet rays from a tungsten arc lamp may also help. Probably any septic organisms which keep up the irritation and cause the ulceration are thereby destroyed. Further, the action of tuberculin locally is facilitated and accelerated if it be combined with other measures, particularly (1) exposure to x rays, giving almost a Sabouraud pastille dose once a week; (2) the application of radium emanations, using 30 mg. for twenty minutes on four successive days, screening that with 1½ mm. of lead; (3) the injection of tuberculin, giving it in minute doses 0.000001 c.c.m. to begin with, every seven

days, and increasing gradually, reaching if possible pure tuberculin. All reactions must be avoided.

Polypharmacy, so called, at times is not without its value. Certain drugs are more efficacious in combination than alone. Likewise tuberculin, combined with other measures, is specially effective. That tuberculin is the deciding factor I have no doubt. The results are lacking in most of the cases, if it be omitted. In using tuberculin locally for pulmonary and abdominal cases the strength that is utilized also depends on the reaction power of the individual. The tuberculin is mixed with linimentum camphorae compositum in the proportion of 1 to 5 minims to 1 drachm. The weakest is used to begin with. That is increased if there be no reaction till the maximum is reached. With such treatment one commonly has witnessed excellent results, in cases of tuberculosis of the abdomen particularly. Many cases could be quoted. The liniment is applied every three or five days, and a flannel binder or belt is kept to assist in its more thorough application. In those cases also the results are greatly accelerated if the treatment be combined with other measures, such as x rays, and tuberculin hypodermically. Cases of lung disease, where the disease causes tightness and pain in the chest, are often greatly benefited.

An extensive trial of tuberculin over many years has convinced one that while it is in certain methods of administration a two-edged sword, it is also a powerful weapon for good. Certainly it should not be relegated to the dust-heap or allowed to sink into oblivion. Its efficiency may be tested in the simple manner outlined above by any practitioner. Those particular forms of tuberculosis are only too common everywhere. The method is absolutely safe. No case, out of hundreds dealt with by us, has to any degree been the worse for the treatment at any time.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

AN ABDOMINAL FORM OF INFLUENZA (?).

During the last few days, following upon a mild epidemic of influenza, we have seen several cases showing unusual symptoms, sufficiently rare in our experience to warrant us in describing them.

From April 18th, when the first case was seen, to April 24th we have observed 10 (8 adults and 2 children), distributed amongst five families. Their chief features are as follows: Puffiness of the face with oedema of the eyelids and redness and oedema of the conjunctivae over the outer half of the eyeballs. The eyelids are drooping, and in some cases completely closed; there is no purulent discharge. In each case there is abdominal pain, referred to the umbilicus, with vomiting, and in some of the cases diarrhoea, with considerable collapse. The temperature is about 102°, and remains so for several days; the pulse rate is not raised in proportion. The tongue is greyish, but not much coated; the abdomen is a little distended and somewhat resistant. A marked feature is pain in the muscles of the neck on flexing the head; the arms and legs feel stiff and heavy, and some of the patients complained of pain in the calves, especially on walking down stairs. There is no albuminuria and no skin eruption.

We shall be interested to know if your readers have seen similar cases.

Reports of Societies.

ABDOMINAL EMERGENCIES.

A MEETING of the Cardiff Medical Society was held on April 11th, with Dr. F. BUCKHAM in the chair, when a paper was read by Mr. GEARY GRANT on abdominal emergencies. He laid stress on the importance of a painstaking history and careful physical examination with such methods as x rays, cystoscopic examination, and differential leucocyte counts where circumstances and time permitted, but deprecated what Mayo termed in another connexion "deadly and scientific delay." The importance of attempting to make an approximate diagnosis was, first, to exclude an extra-abdominal condition simulating an acute abdomen. The case described at that meeting by Professor Emrys-Roberts well illustrated this, and showed that although an exploratory

laparotomy was in many cases fairly free from risks it was not always so, and, in the case referred to, proved fatal. Secondly, it was of great importance that the location of the lesion should, if possible, be determined in order that the incision made should give the best possible approach. The incision, for example, to remove an appendix was quite unsuitable for dealing with a perforated gastric or duodenal ulcer, and required either undue extension, with severance of motor nerves, or a fresh incision and unnecessary waste of time. He gave a short list of some of the commoner conditions outside the abdomen which mimicked the acute abdomen, and some of those conditions, which, whilst abdominal, did not require surgical treatment, among these being Henoch's purpura, which on occasion simulated intussusception. He stated that he was of opinion that, with a small child under an anaesthetic, it was always possible by a combined rectal and abdominal examination to feel the intussusception. Among abdominal emergencies he related a case which was taken into the surgical unit at King Edward VII's Hospital, Cardiff, of a man crushed between buffers, when, on exploring the abdomen, a coil of proximal jejunum was found to be torn across for two-thirds of its circumference, with the mucous membrane protruding as a rosette, but without the escape of the smallest amount of intestinal contents. He instanced this as an example of protective sympathetic stimulation with inhibition of peristalsis and spasmodic closure of the pylorus, and of the possible duodenal splint described by Ochsner, Murphy, and Cannon, and quoted by Dr. Langdon Brown, in which it was found that after high intestinal suture, for nearly six hours after recovery from anaesthesia, the pylorus remained tightly closed, the period of time required for primary sealing of the intestinal wound (*Physiological Principles of Treatment*, Langdon Brown). In the above case, after repair of the intestine, the abdominal wound was closed without drainage and the patient recovered without any untoward symptoms.

Among other cases described by Mr. Geary Grant was one of Sampson Haudley's ileus duplex, and also a case of mesenteric thrombosis of forty-eight hours' duration, where two feet of bowel were found to be gangrenous and were resected, the ends being closed and a lateral anastomosis performed; the patient died in twelve hours. He stated that such a measure should never be adopted, that the only chance for the patient was resection of the gangrenous gut widely, and the tying in of a Paul's tube at each end.

Mr. J. BERRY HAVENCAFT said that in his experience perforation of the small intestine generally produced the appearance of a rosette as described by Mr. Grant, but that single perforations, unaccompanied by crushing or other abdominal lesion, were usually associated with extravasation of faeces. In jejunal perforations there was more extravasation than in those of the lower ileum, and this was probably due to the thicker muscular wall of the jejunum contracting more actively than that of the ileum. In multiple severe injuries of the intestine and mesentery, on the other hand, complete paralysis often supervened, and there was no extravasation, the coil of injured gut lying beneath the wound, and the abdominal wall remaining flaccid, with slight tenderness over the damaged bowel, though the patient presented the general appearance of grave abdominal lesion. Paralytic ileus continued in many of these cases after resection.

Professor E. EMERY-ROBERTS and Dr. H. A. HAIG showed the following specimens and sections:

1. The case of a man admitted to hospital as an acute abdomen on March 13th, 1922. Pain radiated to the left testicle, and there was violent vomiting; the symptoms abated somewhat, but laparotomy was decided upon and carried out on March 21st; no abdominal lesion was discovered. Shortly after, vomiting restarted, becoming faecal in character on April 1st; death ensued on April 4th. At the autopsy the following sequence of events was recorded: On the auricular surface of the mitral valve were two elongated vegetations, each 1.5 cm. by 0.5 cm.; the left kidney was the seat of a recent infarct; coils of the jejunum had become fixed by adhesions to the laparotomy wound; and a volvulus of a portion of the gut, accompanied by great dilatation of the proximal end of the jejunum, together with the duodenum and stomach, had supervened.

2. Carcinoma of the proximal end of the appendix, accompanied by great hypertrophy of the muscular coats of the viscus. The carcinomatous growth was limited to the base of the appendix, the caecum not being invaded. Clinically the symptoms resembled those of appendicitis.

3. An appendix removed at operation, subsequently fixed and bisected in the longitudinal mesial plane. It demonstrated the presence of an oval stercolith, 1 cm. by 0.5 cm., at a distance of 1 cm. from the tip. At its distal pole was a perforation, through which protruded a small accessory stercolith. The surrounding tissues showed acute inflammatory changes.

4. Consecutive sections of an epithelioma of the jaw, during treatment by radium. They showed increasing degenerative effects, due to the action of the radium, and, in addition, the proteolytic action on the epitheliomatous tissues of the secondarily invading bacteria. Whereas in the earlier sections the tissues were infiltrated to a considerable degree by polymorphonuclear leucocytes, these had decreased and had almost disappeared in the most recent section.

MILK AND THE PUBLIC HEALTH.

A MEETING of the Section of State Medicine of the Royal Academy of Medicine in Ireland was held on March 24th, with the President, Dr. T. HENNESSY, in the chair, when Dr. J. W. BIGGER read a paper on the subject of milk and the public health. He said that artificial feeding of infants introduced a great number of dangers which were not present in breast feeding. Cow's milk differed chemically from human, but its constitution could be modified so as to render it a suitable food. The great danger in the use of cow's milk was the presence of bacteria, which might come from disease of the cow, disease of the milker, or from the addition of cow's faeces to the milk. Tuberculosis was the most important disease of the cow transmissible to man, and 8 per cent. of Dublin milks were found to contain tubercle bacilli. Tubercle-free herds were essential, and these could be secured by routine tuberculin tests. Repeated veterinary inspection of the cows and medical inspection of the workers could prevent any great epidemics of infectious disease due to milk. Infantile diarrhoea, from which 382 deaths occurred in Dublin last year, was probably the most fatal disease due to milk. Its cause was to be found in dirt, chiefly in cows' faeces. An examination of 100 Dublin milks showed that they were grossly contaminated, but not more so than the milks of other cities in which no regulations as to the cleanliness of milk were in force. Clean conditions at the time of milking and the thorough cleansing and sterilizing of milk vessels would secure clean milk. An experiment at a farm was described. By the adoption of simple precautions to prevent the access of dirt to the milk, and without special apparatus, it was found possible to reduce the number of bacteria to about one-thirtieth of those present under the old conditions. The time taken by this clean milk to sour was about three times as long as before the institution of the clean conditions—about 185 hours on an average. Dr. Bigger advocated a scheme for the supplying of pure certified milk similar to those in England and the United States, and also of the fixing of maximum standards of bacterial contamination. He appealed to the members of the Academy to impress on their patients the importance and the practicability of clean milk and the dangers of dirty milk.

Sir ANDREW HORN mentioned the gradual evolution of infant feeding from the time when he was a student in the Rotunda Hospital, where a large number of wet nurses were employed, through the various stages of bottle feeding. In his experience cow's milk was a dangerous food for infants during the summer months, and dried milk was accordingly used by him. The effect of Government control in Denmark pointed to the necessity of similar schemes for the securing of clean milk in Ireland.

Dr. ELLA WEBB expressed the opinion that there was no really satisfactory substitute for fresh clean cow's milk. She had not been successful in the use of dried milks, and preferred condensed milk supplemented by cod-liver oil, orange juice, and raw eggs.

Dr. SOLOMONS gave some experiences of his work in a baby club, and pointed out that when a baby was given clean milk from the model farm it did well, but when it was put on a bought milk it lost weight and suffered from diarrhoea. He mentioned that in his experience maternity nurses delighted in bottle feeding. He was pessimistic as to the possibility of a pure milk supply, and thought pasteurization a more practicable step.

Dr. FITZGERALD asked if the danger lay with the bacteria or with their poisonous products in the milk. He believed that town dairies were very beneficial, as their milk could be obtained fresh. During the summer months he used unsweetened condensed milk, which he found more satisfactory than dried milk. In cases of diarrhoea it was important to examine the conditions under which the milk was kept in the home. Vessels and bottles were often filthy even in good-class houses.

Sir JOHN MOORE explained that the connexion between the outbreak of infantile diarrhoea and the temperature four feet under ground was due to the onset of a plague of flies. He

mentioned the filthy conditions of the milk churns at the railway stations.

The PRESIDENT thought it well to consider the industrial aspect of the milk trade. Irish dairy cattle had been sacrificed to beef, and the Limerick cow had been replaced by the shorthorn, which is very prone to acquire tuberculosis. He advocated a model farm in every county and the elevation of the position of the milker. In his opinion the breeding of goats was desirable.

Dr. T. T. O'FARRELL, Dr. KIRKPATRICK, Dr. DE BURCA, and Sir JOHN LUMSDEN also spoke.

FOOD POISONING DUE TO GAERTNER'S BACILLUS.

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland, held on March 31st, the President, Dr. O'KELLY, read a paper on an outbreak of bacterial food poisoning, due to the *Bacillus enteritidis* of Gaertner, which occurred in October, 1921. The outbreak took place in an institution, at least 150 out of 170 of the inmates in one block of the building being affected. With the exception of a few servants, no other members of the institution fell ill. The only article of food not common to the occupants on the day on which the outbreak started was porridge and milk at breakfast. This was served only to the occupants of the affected block. The symptoms were headache, vomiting, nausea, abdominal pain, and diarrhoea, with a temperature reaching in some cases 104° F. No death occurred, convalescence was rapid, and no after-effects were observed. The average incubation period was about twenty-five hours. In searching for the source of infection of the milk which was regarded as the vehicle, it was found that one of the servants attached to the institution had suffered from an attack of gastro-enteritis a week previously. This servant was not attached to the kitchen, but worked in an adjoining portion of the building. It was suggested that this man was responsible for the infection of the milk, either indirectly through flies carrying the organism from a lavatory used by the servants which was about fifty yards distant from the room in which the milk for porridge was set aside, or directly by infecting the milk with soiled hands. It was not established that he was in the habit of taking milk from this supply, but he had access to it, and this alternative hypothesis was put forward. Gaertner's bacillus was recovered from three out of four samples of faeces from victims of the outbreak, but the faeces of the servant who was regarded as the temporary carrier gave a negative finding. His faeces were only obtained with difficulty some six weeks after his recovery. The blood of some of the victims and that of the servant carrier, collected during the outbreak, possessed agglutinins for Gaertner's bacillus in low dilutions. Some weeks later fresh samples of blood yielded higher titres. The organism isolated behaved on culture media like other members of the Salmonella group. It agglutinated with an anti-Gaertner serum, and was pathogenic for mice. The servants attached to the institution, with the exception of five who had access to the milk served with the porridge, escaped infection, although they used the peccant milk at their breakfast. Their escape was explained by the fact that the milk had been added to the tea in bulk, and experiments carried out by Dr. O'Kelly showed that the temperature to which the organisms were exposed was sufficient to kill them.

This was the second outbreak of bacterial food poisoning recorded in Ireland, and another interesting feature was the vehicle; only nine outbreaks in which milk was at fault had been collected by Savage in the British cases, and none in the Continental records. (The investigation was carried out under a grant from the Medical Research Council.)

Ovarian Pregnancy.

Dr. LANE showed a specimen of ovarian pregnancy. The patient had menstruated three weeks before admission, and came in to hospital as a possible case of appendicitis. On operation a clot containing the foetus was found in the abdomen which had evidently come from a sac which was visible in the ovary. The operation was performed by Sir William Taylor in the Meath Hospital. Dr. ROWLETTE expressed interest in the recording of another case of ovarian pregnancy, which he believed to be only the second recorded in Dublin. The case appeared to be a genuine one. Dr. HENRY STOKES, who had been present at the operation, said that the tubes were quite intact, but there was a hole about the size of a shilling in the back of the right ovary.

HEREDITARY CLEIDO-CRANIAL DYSOSTOSIS.

A MEETING of the Ulster Medical Society was held in the Medical Institute, Belfast, on March 9th, with the President, Dr. ROBERT HALL, in the chair, when Mr. S. T. IRWIN showed a case of hereditary cleido-cranial dysostosis, a disease first described in 1897 by Marie and Sainton, and so named by them. Descriptions of less than 100 cases occur in medical literature. In 1910 Fitzwilliams contributed the first considerable article in English in the *Lancet*, reviewing the 60 cases found up to that time. In 1918 La Chapelle published his thesis on the malformation, whilst Jansen in 1912 discussed the causation of the disease and its allied conditions—achondroplasia, mongolism, etc. The disease was essentially a dystrophy of membranous bones just as achondroplasia was a dystrophy of cartilage bones. Mr. Irwin's case showed all the typical deformities associated with dysostosis. The child (aged 7) was small for her age; the head was large by comparison with the face; all the fontanelles could be felt by palpation; the anterior fontanelle was as big as a five-shilling piece; the base of the skull was short as compared with the width; the face bones were deficient in lime salts; the nasal bones were hardly recognizable on x-ray examination. The dentition was somewhat delayed, though not markedly so; the central portion of the lower jaw (the part derived from Meckel's cartilage) was better developed than the ramus. Each clavicle consisted of two separate parts, the inner in each case being the longer. The parts were separated on each side by about a fingerbreadth. Only the outer ends were bony, the inner being cartilaginous. All the movements at the shoulder were greatly increased in range, and the shoulders could be brought together in front of the chest. There was no abnormality in chest or abdomen. Both femoral necks were in the position of coxa vara, and there was a well-marked lordosis on the lumbar spine. There was a deficiency of bone on the pelvis, the symphysis pubis and both rami, as well as part of the ischial ramus, being unossified. The proximal phalanx of the great toe was longer than normal, and the terminal phalanges of the fingers and toes were more pointed than usual. After demonstrating the deformities on the patient, a series of lantern slides of x-ray and other photographs were shown illustrating the contrast between dysostosis and achondroplasia. Mr. Irwin concluded by an account of Jansen's theory of increased amniotic pressure as the cause of the condition, and compared it with the work of Stockard, who produced deformities in fishes by delaying development at "moments of supremacy" during the growth of the embryo.

X-Ray Therapy.

Dr. R. M. BEATH read a paper entitled "X-ray therapy: its biological action and scope in medicine". He gave a brief notice of the history of the subject and of the difficulties of the early workers; great advances had been made, but it was still in its infancy, and explained the physics and technique of the subject. In regard to x-ray therapy in medicine he dealt first with the superficial conditions; the most striking success was in ringworm of the scalp, where the epilation action in the cure was well known. In hirsuties a permanent alopecia would be required and the risk of telangiectasis and atrophy was too great. Hyperidrosis of armpits was relieved by a few applications at three weeks' interval. Pruritus ani, syphilis, psoriasis, scaly eczema, lichenification, and keloid were all relieved or cured, sometimes dramatically, sometimes with little change. Lupus vulgaris was very hopeful, but not lupus erythematosus. The early and middle grades of acne vulgaris were amenable to x-ray, although curable by ordinary local means, but where there was nodulation with fibrotic or keloidal changes there was a direct indication for x-ray treatment; no other agent could reach the deeper seated lesions and cause their involution. Rodent ulcer also yielded. Of the deeper seated affections it was a very valuable remedy in exophthalmic goitre, although of little in simple goitre. Of 14 cases 3 improved out of all recognition, 7 showed a very considerable improvement, 1 was a total failure, and 3 did not return. Dr. Beath then gave details of the signs of improvement in these cases: six treatments twice weekly, repeated after an interval of three weeks, were usually sufficient as regards tuberculous glands; the most striking results were obtained where the neck was full of glands breaking down and caseating, with sinuses and ulceration. The swelling also disappeared in Hodgkin's disease, but the results were not permanent, and the swellings appeared elsewhere; the same held good with

spleno-medullary leukaemia. In enlarged prostate the results so far did not suggest superseding of operation. In operable malignant disease operation followed by post-operative radiation was the best treatment.

A meeting of the Ulster Medical Society was also held in the Belfast Medical Institute on March 23rd, when Mr. REGINALD MORTON gave an address on recent developments in x-ray therapeutics. Mr. Morton dealt very exhaustively with the present position of x-ray therapeutics in regard chiefly to cancer. He said that the profession must readjust its mind to these methods of treatment, but at the same time he deprecated the unfortunate publications in the daily press. He gave the history of a number of cases, pointing out success and failure. To carry out the treatment it was necessary for the operator to devote his whole time; it was unquestionably a "whole-time job." Future years would show the permanency of the improvements and cures, or the return of the disease. A number of Fellows made remarks and asked questions; it was felt that the new developments were a great advance, but that time was required to assign its exact value.

TREATMENT OF TUBERCULOSIS.

At a meeting of the Tuberculosis Society held at the Margaret Street Hospital, London, W., on April 24th, there was a prolonged discussion on the therapeutics of tuberculosis. The chair was taken by Dr. F. R. WALTERS, who in his opening paper emphasized the importance of adequate treatment of slight fever in pulmonary tuberculosis, and suggested that slight attacks were so often neglected because no adequate temperature record was taken. The general practitioner should deal with slight fever far more strictly, and the worst thing that could be done was to tell the patient he must walk about out of doors. In the early stages there should be a combination of rest and fresh air. The patient must be kept warm, while having plenty of cool air to breathe. There should be physiological as well as physical rest, and an absence of all emotional disturbance, worry, or excitement. Treatment causing fatigue should be avoided as much as possible, and in some feverish cases, in dealing with patients in an institution, it might be necessary to restrain the nurse's excessive zeal for washing. It was always a great mistake to tire the patient out. Dealing with various remedies, Dr. Walters said there was a distinct place for creosote, but it should be prescribed rather in a liquid form than in capsules. It should be well diluted and given after meals. In his own experience, continuous inhalations had been rather disappointing. There were cases of irritating cough where the remedy might be very useful, but a great drawback was the fact that patients who had been under fresh-air treatment much resented having what they called "muzzles" put upon them. Speaking of more serious attacks of fever, Dr. Walters said he felt strongly on the question of diet. He had known a man to lose his chance of recovery because the practitioner who treated him in the early stages of the febrile attack put him on low diet. The patient ought to be fed to a reasonable extent on digestible food, but not on slops. In regard to haemoptysis, complete rest was of course necessary in severe cases. The patient should be kept in a recumbent position, and not flat on his back. Cool air was essential. Ice to suck was of little value, except as an adjunct to prevent thirst. Silence was important. He was strongly opposed to the routine treatment by morphine. The patient could be quieted in other ways. Inhalations of turpentine proved very useful. In severe haemorrhage the amount of liquids taken should be restricted to 15 oz. a day. The intermuscular injection of calcium chloride had been found very effective.

Dr. NEVILLE COX read a paper on artificial pneumothorax, which he thought was the greatest advance in the treatment of pulmonary tuberculosis made in the past fifty years. Pointing out how difficult it was to tabulate statistics he claimed that if only 1 per cent. were saved by the treatment it would be well worth while. There were of course the risks of gas embolism and pleural shock. These might be avoided by careful technique. In his own experience since the war he had never used the treatment except when what he might call the classical indications were present—that is, extensive, progressive, apparently unilateral cases, with abundant bacilli and persistent fever. Probably suitable cases would not comprise more than 3 or 4 per cent. in a sanatorium. Dr. Neumann, of the Sebatzalp, Davos, said about 12 per cent.

was the average, but he thought that too high. There was scope for a great deal of judgement in the selection of the cases. He suggested that a stage had now been reached at which pneumothorax might be more extensively used.

Dr. JANE WALKER agreed with Dr. Cox. Pneumothorax, she thought, should be offered to a patient who had been in a sanatorium for six months and who was making no progress. In her own experience there had been disappointments, but she believed more than 1 per cent. were saved by the treatment. In reply to Dr. Cox, Dr. Walker said refills might be done at the dispensary, but patients should be given time to lie down and rest. In reply to the Chairman, Dr. Walker said it was most difficult to say for what length of time injections should be continued. The intervals might gradually be lengthened. Children did not require as long a period as adults. In some cases the treatment had to be continued for four or five years, or for all the patient's lifetime.

Dr. H. A. ELLIS mentioned a suggested classification of humanity into "acid persons" and "alkaline persons"; according to this notion tuberculosis was an alkaline disease, and as a case got worse, the alkalinity increased. The alkaline person had a low blood pressure, which always went with tubercle. He and his fellow workers came to the conclusion that very rarely did a person with a blood pressure of 125 mm. Hg suffer from active tubercle, whereas with the pressure down to about 115 mm. there was always danger. If they increased the acidity of the patient they improved his chances enormously. These conclusions had driven them towards acid forms of medicine, and, although difficulties had to be faced, the results had been encouraging. Dr. Ellis gave further particulars, dwelling especially upon the newer methods of testing urine. An individual in normal health had an alkaline morning tide every day.

Dr. SANDISON gave some details regarding his recent visit to Switzerland. He was still perplexed as to the real value of the altitude treatment, which, of course, could not be applied to industrial cases. There were cases in which it was beneficial, and it might be well worth trying. He did see cases, however, which should never have been allowed to make the journey. Some doctors still advised an immediate journey to the Alps, when it was the very worst thing that could happen to the patient.

The question of x-ray control, raised by Dr. HERNAMAN JOHNSON, was also discussed.

SYPHILIS OF THE HEART.

A MEETING was held on April 7th of the West London Medical-Chirurgical Society, with the President, Sir G. LENTHAL CHEATLE, K.C.B., in the chair, when a paper on syphilis of the heart was read by Dr. HAROLD WILTSHIRE. He referred to the supposed rarity of this condition in former days, but changes in the heart and aorta were, however, of common occurrence in syphilis. Statistics showed that the myocardium and coronary arteries were frequently affected. Infection of the heart began in the secondary stage of syphilis. It could be compared to a septicaemic condition in which the *Spirochaeta pallida* were circulating in the blood and invading the perivascular lymphatic spaces through terminal blood capillaries, setting up there a round-celled infiltration as a tissue reaction against this invasion. In the secondary stage careful examination of the heart would often reveal irregularity, cardiac embarrassment, or other signs of disordered action, indicating this early infection. Syphilis of the heart usually occurred as a primary aortitis and not as a primary endocarditis. The pericardium and endocardium were scarcely ever affected. In the later stages, the disease appeared as a diffuse myocarditis or as an aortitis. In the latter condition, the first part of the aorta was usually affected just above the valves and the openings of the coronary arteries. The infiltration spread transversely, then quickly upwards, and more slowly downwards—the latter direction being the more important. Diagnosis was easy where myocarditis and aortic lesions were present. Cases of insidious heart trouble without any definite cause, especially in middle-aged patients, should give rise to the thought of syphilis. The symptom of pain, as a sense of constriction behind the sternum, was very suspicious in such cases. In aortic regurgitation statistics showed 70 per cent. of cases were due to syphilis. Regarding treatment, great care should be exercised in giving salvarsan to cases where the coronary arteries were involved. It was considered safer to begin with a course of mercury iodide, with rest in bed, and followed by salvarsan given cautiously. The prognosis was extremely bad, for hardly a case lived for more than three years after diagnosis.

Reviews.

A HISTORY OF NURSING.

THERE is scarcely anything which gives such an assurance for present good and future progress on sound lines as a well-balanced veneration for the past, based upon a good knowledge of history. If only such a knowledge were more common, how many mistakes in the development of the commonweal, what repetition of identical or similar experiments, each foredoomed by the record of history to failure, would be avoided! To none is a history of their art and craft more needed than to those who serve. Doctors, nurses, and teachers, whether of learning or religion, each need in a very special manner to know what the forebears in their own mystery did and attained. For the nursing sisterhood Miss LAVINIA L. DOCK, the Secretary of the International Council of Nurses, and Miss ISABEL MAITLAND STEWART, of the Teachers' College, Columbia University, have done a good work in their volume entitled *A Short History of Nursing*.¹

Nursing is a very ancient profession; it is as old as motherhood. It has flourished in many forms and been deeply affected by great social movements. It has been in the homes as good and as bad as the home life of the people. It has ever been the handmaid of medicine, and it has fluctuated as medicine has been aroused or fallen into sleep. In a very old Indian description of a model hospital it is said that the nurse should be—

"skilled in every kind of service that a patient may require, endowed with general cleverness, competent to cook food, skilled in bathing or washing the patient, well conversant with rubbing or massaging the limbs, lifting the patient or assisting him to walk about, well skilled in making and cleaning beds, ready, patient, and skilful in waiting upon one who is ailing, never unwilling to do anything that may be ordered."

Those nurses were young men belonging to snbeastes of the Brahmins or priestly orders. Hippocrates makes no mention of nurses by name, though his writings and those of his followers give the entire technique of what would now be called nursing in most minute detail and with a perfect understanding. Probably the medical students did this work. In Christian times nursing has been greatly associated with religion, not always with advantage. St. Chrysostom (the author of one of the most beautiful of ancient prayers in the English Prayer Book) enjoined a stern asceticism upon the nurses or deaconesses, but one direction was to go unwashed! Three great military nursing orders—the Knights Hospitallers of St. John, the Teutonic Knights, and the Knights of St. Lazarus—at one time provided excellent nursing services, and made provision for a corresponding order of women. Many of the hospitals built by the Knights Hospitallers were of great architectural beauty and were furnished in the most complete way known to their times. As late as 1783, at the time of the earthquake in Sicily, the Order of St. John did brilliant work in the relief of the sufferers.

When medicine declined in the West the arts of medicine and nursing were fostered amongst the Arabians, who became especially eminent in the care of eye cases and of the blind. In the Middle Ages many orders of secular and religious nurses were established, such as the followers of St. Francis, the "Brothers Minor," and of Clarissa, the "Poor Clares." The influence of ecclesiasticism sterilized the efficiency of the higher grades of these orders, but the "tertiaries," who did not leave their homes and renounce the world, carried on valuable work amongst the poor and sick, and these orders do good service in Italy to-day. Many famous nurses of mediæval times are now canonized. In Flanders the Beguines antedated the work of St. Francis, and their founder, a priest, asserted their claim to freedom of thought and action, so that they were subject to accusations of heresy and of thinking it unnecessary "to fast, or to obey mortal men." One of the most famous of their hospitals exists in all its beauty to-day at Beaume, in France. The hardening effects of ecclesiastical authority on the one hand, and of puritanism on the other, had disastrous results upon nursing for many years. The nun might not care for or even look at any of the parts of the human body except the head and extremities. The lay nurse became a "Sairey Gamp." The building of modern nursing began with

the work of Vincent de Paul and the Frenchwomen associated with him. He was a simple parish priest, whose study of social conditions brought him to a most advanced point of view, one indeed that was considered revolutionary. He advocated education for the young, including manual training and the teaching of skilled trades. To deal with beggary he proposed farm colonies and graded work. He saw that some individuals could never maintain themselves, and believed that it was the duty of organized society to care for them. To deal with poverty he desired first friendly visiting so that the poor might be known personally, and then relief that did not overlap or fail. Charity was not to consist of alms but of constructive aid. A Parisian lady who became conscious of the needs of the patients in the Hôtel-Dieu of Paris persuaded him to organize a band of lady visitors, and so came about his Sisters of Charity; he did not allow them to take vows; they served on an annual contract, and were free to leave and to marry.

"My daughters," he said, "you are not religious in the technical sense, and if there should be found some marplot among you to say 'it is better to be a nun,' ah! my daughters, your company will be ready for extreme unction. Fear this, my daughters, and while you live permit no such change; never consent to it. Nuns must needs have a cloister, but the Sister of Charity must needs go everywhere."

Since then there has been a steady revival of the art of nursing. Many have contributed to it: Howard, the prison reformer, and Elizabeth Fry, the Quaker, in England; Amalie Siorecking and Pastor Fliedner, the founder of the deaconesses of Kaiserswerth in Germany, who learned much from Miss Fry, and who in turn gave her first lessons to Florence Nightingale, who went there first as a visitor and later for a longer stay. That brings us to the critical period of modern nursing, which developed in the Crimean war, and afterwards was carried to other countries by many workers, amongst whom ranks Edith Cavell as the messenger of the new craftsmanship to Belgium.

This book deals with all these developments in a lucid and readable fashion, and enters into some detail on the present state of nursing in various countries and of the status of nurses. It is well worth the reading of every nurse, be she a novice or one of years of service. It will be an inspiration to each. We commend also to the notice of the chiefs of training schools for nurses the variant of the Hippocratic oath written by Mrs. Cadwallader Jones, a member of the board of managers of the City Hospital, New York:

"You do solemnly swear, each by whatever she holds most sacred—

"That you will be loyal to the physicians under whom you serve, as a good soldier is loyal to his officers.

"That you will be just and generous to all worthy members of your profession, aiding them when it will be in your power to do so.

"That you will live your lives and lead your profession in uprightness and honour.

"That into whatsoever house you enter, it shall be for the good of the sick to the utmost of your power, and that you will hold yourself aloof from all temptation.

"That whatsoever you shall see or hear of the lives of men and women, whether they be your patients or members of their households, you will keep inviolably secret, whether you are in other households or among your own friends."

TRACHEO-BRONCHOSCOPY.

SOME six years ago Dr. M. MANN of Dresden wrote in German an essay on tracheo-bronchoscopy forming a kind of appendix to the atlas he published in 1911. An English translation has now been published with the title, *Textbook of Tracheo-Bronchoscopy*.² The first fifty-four pages of the book are devoted to an excellent account of the instruments and technique employed in tracheo-bronchoscopy. The second part deals with practice; its first chapter, of some eighty-five pages, concerns the extraction of foreign bodies, and in it are recorded case reports of every sort of foreign body which has found its way into the trachea or bronchi. The reports are minutely classified and subdivided, and many of the cases are of great interest and highly instructive. They are so numerous, however, that the effect is somewhat laboured and tedious, the text being overburdened with detail. This part concludes with a dissertation on the indications and contraindications for upper and lower bronchoscopy, and

¹ *A Short History of Nursing, from the Earliest Times to the Present Day*. By Lavinia L. Dock, Secretary of the International Council of Nurses, with Isabel Maitland Stewart, A.M.R.N., of Nursing and Health, Teachers' College, New York and London: New York, New York and London: 8vo, pp. 398. 17s. 6d. net.)

² *Textbook of Tracheo-Bronchoscopy (Technical and Practical)*. By Sanitätsrat Dr. M. Mann (Dresden). Translated by A. R. Mordie, M.A., M.D., Ch.B., F.R.C.S. Edin. London: John Bale, Sons, and Danielson, Ltd. 1920. (Sup. roy. 8vo, pp. 292; 15 plates, 52 figures. 31s. 6d. net.)

finally ends with the aphorism, "Never the upper from vanity, never the lower from indolence." These final pages are helpful, and the conclusions of the author seem well reasoned, but it is perhaps right to say that his views, and especially the aphorism, have been severely criticized by Dr. Chevalier Jackson.

The remainder of the book is devoted to tracheo-bronchoscopy in diseases of the trachea and bronchi, and to diseases of the tracheo-bronchial tree resulting from pathological changes in its surroundings. In this the author makes a plea for a more extensive use of bronchoscopy in general medicine, a field which he believes has been neglected. This section, again, is very detailed, and many cases are quoted. The results seem, however, to have been more of scientific and academic interest than of practical benefit to the patients; enthusiastic as he is, the author will probably not carry most of his readers quite so far as he would wish. This part, however, is a valuable and in some respects original contribution to scientific medicine, and is worthy of close study. At the end of the book are several beautifully executed plates in colour. Although much has been written on this subject there are few handbooks, and this one by Dr. Mann is a valuable addition to the number.

GALL STONES.

THE first edition of Professor CHAUFFARD's charmingly written and authoritative *La Lithiase Biliaire* appeared in 1914 (and was reviewed in this column on May 16th, p. 1073), and the second edition,³ though preserving the same arrangement, contains much new material, including a chapter on the diagnosis of gall stones by x rays, and seven new plates. This work is especially welcome, as it combines the ripe clinical experience and literary knowledge of a foremost French physician, with an account of researches into chemical problems connected with the subject which have been carried out in conjunction with Grigaut, Brodin, and Guy Laroche. While allotting a due share of credit to Nauwyn's view that gall stones are the local product of inflammation of the mucous membrane of the gall bladder, the claim that it is an exclusive cause is successfully combated, thus agreeing with Aschoff's and Baumeister's conclusions as to the aseptic formation of pure cholesterol calculi. Chauffard and his co-workers have shown the existence and importance of an excess of cholesterol in the blood as a cause of gall stones, and Grigaut ascribes this excess to failure of the liver cells to excrete cholesterol into the bile in the form of cholic acid, which is a solvent for cholesterol. A new and interesting observation, illustrated by two plates, is Gosset, Loevy, and Magrow's that multiple small faceted calculi originate inside the villi of the gall bladder as minute collections of cells surrounded by cholesterol; these are shed, grow, and, at first round, subsequently become faceted, their multiplicity and similarity being thus explained. Chauffard has made a special study of the points that become tender on pressure in biliary colic; this is perhaps rather a difficult subject from the comparatively large number of these spots; of these eight points two are due to his own observations—the pancreatico-choledocian zone just above and to the right of the umbilicus, which is often as definitely marked out as McBurney's point in appendicitis, and the right phrenic spot between the two heads of the sterno-mastoid muscle which is of value in the differential diagnosis from appendicitis and disease of the pylorus.

In the new chapter on skiagraphy in gall-stone disease a graceful reference is made to the work of the American radiologists; the importance of employing soft rays is insisted on, and an account of the detection of adhesions in connexion with the biliary tract is given. In reference to the transparency of gall stones composed solely of cholesterol a case is described in which the thick bile cast a shadow while three contained calculi were invisible. The limitations of skiagraphy in diagnosis are pointed out, one being that the number of calculi shown may not correspond with that actually present. The discussion of the indications and contraindications for operation represents the position of a broad-minded physician who is not inclined to yield up the whole of his province to the enterprising surgeon; thus he is not in favour of routine operation in the early stages so as to avoid complications in the future, for though the operative mortality (1 to 2 per cent.) of such cases is low, it is higher

than that of hepatic colic; further, the analogy of a first attack of appendicitis, a far more dangerous condition, is not exact. The cases in which operative interference is advisable are those complicated with infection, those with much pain, and those with chronic jaundice.

To sum up, this work is a most up-to-date and attractive account of gall-stone disease from the physician's point of view, and contains much information about its medical treatment.

RADIOLOGY OF THE HEART AND GREAT VESSELS.

DR. R. CHAPERON has been induced to write a book on his anatomical and radiological studies of the vessels at the base of the heart,⁴ because so many observers have differed on material points in regard to the interpretation of the right and left sides of the central thoracic shadow, as shown by radiography. In the first portion of the book the diagrams and opinions of many authors are set forth. The method the author used in this research is exactly described, and then the shadows to the right and left sides are discussed and compared, the radiographs reproduced as illustrations, showing the various vessels injected with opaque material. The shadow of the aortic arch is dealt with very completely, and the author seems to have proved conclusively that, in the normal, the ascending portion of the aorta takes no part in the formation of the shadows in the upper right side, but is well inside the whole of the superior vena cava, the whole of this upper right shadow being caused by the latter.

We can recommend this essay, which is written clearly and is also well illustrated, to all radiologists; it will be of especial value to those interested in the radiology of the heart and great vessels, a branch which has been somewhat neglected in this country, but has received attention from many French writers.

ORGANIC CHEMISTRY.

A TRANSLATION by Dr. Spielman of Volume I of Richter's *Organic Chemistry* was published some time ago; the translation of Volume II⁵ by Dr. D'ALBE is now completed. It contains only those substances of the group described as "carbocyclic compounds," a term referring to bodies having a ring structure but including only those in which no element but carbon participates in the formation of the ring. Formerly a textbook of organic chemistry might be roundly complete and yet not exceed moderate dimensions. To-day the attempt at completeness will produce a volume of cyclopaedic dimensions unless recourse be had to drastic abridgement which must at length lead to diminished usefulness. The limit to which abridgement of description should be carried in preference to the omission of less essential subject matter is probably reached in the present volume, which contains within 728 octavo pages the quantity of matter covered by an index of over 5,000 entries; for the work has been almost reduced to the character of a collection of notes. The following quotation from the article "Adrenalin," page 370, illustrates the style:

"On heating with NaOH it decomposes with elimination of methyl-amine. Methylation and subsequent oxidation produce veratric acid. This settles its constitution, which is confirmed by synthesis. The latter starts from chloraceto-pyro-catechin (obtained from pyro-catechin and chloracetyl chloride), which yields inactive adrenalin by transformation with methyl-amine and reduction with Al amalgam."

Doubtless there is a large class of workers to whom this volume will prove useful, since it provides in a readily accessible form information on physical constants, memoranda on relationships of substances, and references to original papers; the latter are abundant. Beyond question its pages contain the utmost information possible in the space allotted, and what is given has been selected with excellent discrimination. The text appears to be extremely accurate. Names of substances under particular consideration are printed distinctively in bold type, thus facilitating perusal and reference. The nomenclature does not agree uniformly with the system generally used in this country, but the divergences need

³ *Étude anatomique-radiologique des vaisseaux de la base du cœur, vue de face*. Par Dr. Robert Chaperon. Paris: Masson et Cie. 1922. (Roy. 8vo, pp. 62; 12 figures, 11 plates. Fr. 6 net.)

⁴ *Organic Chemistry, or Chemistry of the Carbon Compounds*. By V. von Richter. Edited by Professor R. Anschütz and Dr. H. Meerwein. Vol. II: *Chemistry of the Carbocyclic Compounds*. Translated from the eleventh German edition by E. E. Fournier d'Albe, D.Sc., A.R.C.Sc. London: Kegan Paul, Trench, Trübner and Co., Ltd.; Philadelphia: P. Blakiston's Son and Co. 1922. (Demy 8vo, pp. xvi+760. 3s. net.)

produce no confusion. To those, however, whose study of organic chemistry is ancillary to another object, such as the study of medicine, the book will afford too little assistance to be greatly valued by them.

GENERAL BIOLOGY.

THE importance of what may be termed general biology is gradually becoming more fully realized. The study of pure morphology became imperative after the publication of Darwin's *Origin of Species*, but the necessity for the acquirement of a knowledge of structural detail is no longer so pressing; indeed, we are nearing the point of surfeit, and biologists are beginning to inquire more actively into the problems of life itself.

Professor ÉTIENNE RABAUD's book, *Éléments de Biologie Générale*,⁶ is written from this aspect, and deals with the subject mainly from a zoological standpoint, though the botanical side is not ignored. The scope and method of general biology are defined in the introduction, in which the author puts forward views that many are now disposed more fully to appreciate. Morphology, it is pointed out, important though it be, is by no means sufficient, and indeed, when studied by itself, has often led to erroneous conclusions. Neither is physiology alone sufficient. Organisms must be studied from all points of view—reactions to environment, variations, and so on. The first chapter is devoted to a consideration of living matter, its physico-chemical constitution and colloidal complexes, tropisms, and tactisms. The summary it contains of the present state of knowledge of these fundamentally important matters is excellent.

Passing from these, Professor Rabaud proceeds to discuss the formation of multicellular organisms. He attaches considerable importance to Massart's experiments on the polarity of vegetable organs published in 1917. Growth, regeneration, variation, adaptation, and the origin of sex are some of the many subjects considered. The much discussed questions of instinct and intelligence are also briefly touched upon. It is perhaps well that the author should have been brief here, for though very much has been written about these subjects, there is as yet little that is definite or agreed upon. It has been impossible to treat any of these many and varied aspects of general biology in anything but a cursory manner within the compass of a small volume. Nevertheless, what has been attempted has been done well, and the book can be recommended to all interested in the subject.

ELEMENTS OF BOTANY.

THE textbook of *Botany for Students of Medicine and Pharmacy*,⁷ by Professor FRITCH and Dr. SALISBURY, sets out to cover the same ground as the syllabuses of the Pharmaceutical Society's minor examination and the various boards for the examination of medical students. The authors have, in addition, endeavoured to give an adequate account of the vegetable kingdom from the biological standpoint, thereby making their text much more interesting to the reader. The book begins with an introduction written by Professor Boycott; then follow twenty chapters in which the structure and functions of plants and their constituent parts are lucidly described. The last ten chapters deal with the various types of vegetation, from algae to flowering plants, their classification and development. The book is well illustrated.

The *Introduction to the Structure and Reproduction of Plants*⁸ by the same authors is a companion volume designed to meet the requirements of higher school examinations in botany and the needs of the first-year students at the universities. The book is written on broad lines, and is admirably illustrated; the index is unusually complete. In this volume there is a refreshing absence of the formality, the stock types, oft-used pictures, and generally uninteresting detail with which many botanical textbooks have made us familiar.

⁶ *Éléments de Biologie Générale*. Par Étienne Rabaud, Professeur de Biologie expérimentale à la Faculté des Sciences de Paris. Paris: Félix Alcan. (Demy 8vo, pp. 444; 51 figures. Fr. 21.)

⁷ *Botany for Students of Medicine and Pharmacy*. By F. E. Fritch, D.Sc., Ph.D., F.L.S., and E. J. Salisbury, D.Sc., F.L.S. London: G. Bell and Sons, Ltd. (Demy 8vo, pp. xiii + 357; 263 figures. 10s. 6d. net.)

⁸ *An Introduction to the Structure and Reproduction of Plants*. By F. E. Fritch, D.Sc., Ph.D., F.L.S., and E. J. Salisbury, D.Sc., F.L.S. London: G. Bell and Sons, Ltd. (Demy 8vo, pp. 466; 239 figures. 15s. net.)

NOTES ON BOOKS.

ARMAND-DELILLE and L. NÈGRE have published a second edition of their handbook, *Technique de la Réaction de Déviation du Complément de Bordet et Gengou*,⁹ a little volume which is intended to be a practical guide to the performance of these serological tests used in the diagnosis of syphilis, tuberculosis, and echinococcus disease. In an introductory section the beginner is made acquainted with the theoretical considerations which it is necessary to understand in order to perform these tests intelligently, and the details of the preparation of the ingredients of the reaction, antigen, complement, and amoceptor, are clearly explained. The technique described most fully for the performance of the Wassermann reaction is that used by Calmette and Massol—namely, the incubation of the patient's serum with increasing quantities of complement; it does not differ from such methods as are described and recommended by the Medical Research Council in this country, except that Calmette and Massol use larger quantities of serum for the test; but other methods are also mentioned. The last three chapters in the book are devoted to a study of the other diseases in which complement deviation is employed for diagnosis, more particularly tuberculosis and echinococcus disease. A fairly comprehensive bibliography is appended, and there are twenty-five good illustrations. The book is primarily intended for students wishing to learn to carry out these tests, and to them this handbook will be very useful. Except for purposes of comparison on some special point it has little interest to other laboratory workers in this country.

Professor KNAPP has written a book giving a general account of the prophylaxis and treatment of enteroptosis;¹⁰ due emphasis is laid on each of the various methods of treatment that can be employed. It is addressed to specialists and surgeons.

We have received the first number of a new monthly journal entitled *Revista de Medicina Legal de Cuba*, which is the organ of the Cuban society of forensic medicine. It contains an interesting article by the editor, Dr. A. B. Fernández, on morgues in various countries.

⁹ *Technique de la Réaction de Déviation du Complément de Bordet et Gengou*. By P. F. Armand-Delille and L. Nègre. Second edition. Paris: Masson et Cie. 1922. (Cr. 8vo, pp. viii + 194; 22 figures, 1 plate Fr. 9 net.)

¹⁰ *Die Prophylaxe und Therapie der Enteroptose. Für die ärztliche Praxis dargestellt*. Von Professor Dr. L. Knapp. Berlin and Vienna: Urban and Schwarzenberg. 1921. (Sup. roy. 8vo, pp. 118. M. 42.)

THE EXISTING FACILITIES FOR POST-GRADUATE INSTRUCTION IN LONDON.

THE munificent offer by the Rockefeller Foundation of two million dollars to defray the cost of building and equipping an Institute of Hygiene in London, which has been accepted by the Minister of Health on behalf of the Government, has fulfilled an important recommendation of the Athlone Committee on Post-Graduate Medical Education, the report of which was published in May, 1921 (see JOURNAL, June 25th, 1921, p. 942). Little progress has, however, been made towards the fulfilment of the main part of the report of the Committee, nor in the present financial state of this country is there much immediate hope of the establishment of the central post-graduate school and hospital which it recommended. In these circumstances it behoves those who are interested in the success of post-graduate teaching in London to make greater use of the facilities already existing; they are not few, and are on the increase.

Before considering the facilities it may be advisable to inquire into the question of what classes of qualified medical practitioners are at present demanding and receiving post-graduate instruction. The Athlone Committee considered that the graduates requiring such instruction might be divided into seven categories: (a) Graduates who have recently qualified; (b) general practitioners of some years' standing, who require general courses in medicine and surgery of a simple and practical nature; (c) general practitioners who seek instruction in special subjects in order to keep abreast of advances in specialties in which they are interested; (d) graduates from home and abroad who seek a higher degree or diploma, such as the M.D., F.R.C.S., D.P.H., or D.T.M. and H.; (e) officers in the R.A.M.C., Naval, Army, Indian, and Colonial Medical Services, who want to keep themselves abreast of clinical work or who are preparing for examinations for promotion; (f) graduates who require facilities for extended medical research; and (g) graduates

from abroad falling into categories (b), (c), and (f). This extended classification may, perhaps, be summarized into recent graduates (including those seeking higher degrees or promotion in the services), general practitioners who want to "rub up" their general knowledge, and general practitioners who require intensive instruction in a specialty. It would seem, therefore, that to accommodate these classes of medical practitioners there are required, in the first place, comparatively elementary courses in different subjects, lasting, perhaps, about a month, and in the second place a series of advanced courses, lasting from perhaps two or three months to a year, to meet the needs of the expert post-graduate student in the specialties or the special examinations for which he desires to prepare.

The body formed by the amalgamation of the Fellowship of Medicine and Post-Graduate Medical Association has bridged the gap in post-graduate instruction with a certain measure of success. It has sought to be a rallying point for medical strangers in London by providing a central inquiry office and reading and recreation rooms. It has for some years enjoyed the hospitality of the Royal Society of Medicine. It has arranged with the medical schools in London and other hospitals for a certain number of post-graduate courses, and its tickets admit the holders to these hospitals and courses. The Fellowship issues a monthly bulletin containing a programme of the work in the hospitals associated with it, specifying the names of teachers and lecturers, together with the time and place at which the instruction is given. The average number of medical practitioners who at present take advantage of the facilities provided by the Fellowship of Medicine is stated to be about thirty-five a month, the majority of whom appear to come from the dominions, the colonies, or from foreign countries. A certain number of the teaching schools in London which formerly adhered to the scheme of the Fellowship of Medicine now, however, act independently, and it is a matter of some difficulty for the qualified practitioner who desires post-graduate instruction to know exactly what facilities there are in existence in London and what may best meet his needs.

While some medical men have a very definite idea of what they want and see that they get it, others, it is to be feared, wander round from hospital to hospital, from clinic to clinic, from operating theatre to operating theatre, and achieve during a not unpleasant holiday merely a great variety of fleeting medical and surgical impressions. With better and more definite co-ordination this comparative waste of time ought not to take place. Perhaps this co-ordination might best come through a liaison between home sources of supply of students, together with the India Office, the Colonial Office, the Foreign Office, foreign embassies and consulates, and a central office keeping itself in touch with all the hospitals giving post-graduate instruction of any kind in London.

We have addressed inquiries to most of the hospitals in London asking what post-graduate facilities they are providing at the present time, and replies have been received from many of them. The subjects of public health and of tropical medicine and hygiene may be mentioned only to be dismissed in a word, for the existing courses for the D.P.H. and D.T.M. and H. in London are well known and adequate. In regard to the diploma in psychiatry, instruction has been organized at the Maudsley Hospital, the Bethlem Hospital, and the National Hospital for the Paralyzed and Epileptic, Queen Square. Classes for higher degrees and diplomas and for examinations for promotion in the services are held at the West London Post-Graduate College (West London Hospital, Hammersmith) and at the North-East London Post-Graduate College, Prince of Wales's Hospital, Tottenham; with these and the special classes (for instance, for the F.R.C.S.) at the teaching schools, the needs in this respect seem to be met. The West London Post-Graduate College also holds complete courses in general medicine and surgery for bringing practitioners up to date, and gives special courses as desired; the number is not limited, the courses last generally from one to three months, and are held throughout the year. At the North-East London Post-Graduate College intensive courses of two weeks are held, which may be described as "refresher" courses, and at these the attendance is limited to thirty; other "specialist" courses are held, lasting from one to twelve months, intended for those engaged in general practice; both types of courses are held throughout the year. The practitioners attending these courses are chiefly general practitioners with a few service men.

At St. Bartholomew's Hospital a vacation course, lasting

nearly three weeks, is held each year during the summer vacation, the numbers being limited, for the purpose of bringing general medical knowledge up to date; a considerable number of graduates also attend the special departments at this hospital. At the London Hospital there is a six months' course for school medical officers (actual and intending) and general practitioners intending to undertake the work of school clinics on a part-time basis; it began this year on February 1st. At Gny's Hospital medical practitioners act as clinical assistants in the various departments of the hospital for not less than three months, but, except for the Fellowship courses, no post-graduate work is carried on, although a course is at present under consideration. At St. Thomas's Hospital a special post-graduate course is in contemplation, limited to fifteen members, but at present the post-graduate work there chiefly takes the form of "hospital practice" and deals with the newer methods of clinical investigation; the view strongly held at this hospital is that a general hospital whose chief duty is to instruct undergraduates is not suitable for extensive post-graduate teaching. The authorities at University College Hospital state that they also are averse to post-graduate teaching at an undergraduate hospital, but post-graduate students who propose to take up special research work are welcomed; practitioners of any nationality are admitted to the ordinary work of the hospital. At the Royal Northern Hospital two schemes of post-graduate instruction are at present under consideration, but otherwise only a course of surgical demonstrations is held, in connexion with the Fellowship of Medicine. At the Hampstead Hospital a course of surgery is conducted in connexion with the Fellowship of Medicine.

At the special hospitals fewer difficulties attend the commingling of undergraduates and graduates for instruction, and many qualified medical practitioners have long been accustomed to attend these hospitals for instruction in the different specialized branches of medicine. In regard to ophthalmic work, Moorfields Hospital has special courses lasting for five months or more, from October to February, and from March to July; facilities are given for special study and for the special examinations in ophthalmology. At the Royal Westminster Ophthalmic Hospital special courses last for ten weeks, but practical and clinical teaching is carried on all the year round; at present a revision course is conducted in connexion with the Fellowship of Medicine. In regard to diseases of the ear and throat, the Hospital for Diseases of the Throat, Golden Square, does not hold any definite courses of study, as the opinion there is that the practical work in the out-patient department and wards fulfils all the requirements. In the past, courses of lectures and demonstrations have been held at this hospital, but its authorities have come to the conclusion that for their special work such courses are not of much value, and that the interests of post-graduate students are best served by developing the clinical work; three to six months is the most usual period for a course of study. At the Central London Nose, Ear, and Throat Hospital, Gray's Inn Road, there were last year 53 post-graduate students; such students usually attend the practice of the hospital for three months. The course of instruction continues without interruption throughout the year, but recently special "intensive courses" have been held, consisting of lectures or demonstrations every day for ten days on particular subjects, and also a special course on methods of examination; apart from the regular post-graduate students, 21 practitioners attended the last intensive course.

At the Brompton Hospital for Consumption there are many post-graduate students, chiefly those who intend to devote themselves to public health and tuberculosis work; these students attend the practice of the hospital for one, two, or three months, up to six months if desired; as some members of the staff are away during August and September this period of the year is not recommended to post-graduate students.

At the Hospital for Women, Soho Square, special courses are held lasting six weeks, commencing in October, January, and March, and the number of students is limited in each course to nine. Instruction is given daily from 2 to 5 o'clock, consisting, in addition to attendance at operations and the out-patient department, of clinical lectures, pathological demonstrations, and demonstrations in radio-therapeutics. At the Samaritan Free Hospital for Women, Marylebone Road, there are no post-graduate courses, but each visiting surgeon has two qualified clinical assistants.

At the Hospital for Diseases of the Skin, Blackfriars Road, demonstrations of cases are given daily, but there are no

special post-graduate courses. At the St. John's Hospital for the Skin there are clinical demonstrations in the afternoons, and a special course of lectures is given by the members of the honorary staff during the winter months, followed by demonstrations and clinical instruction on special cases; a special course of practical instruction on the bacteriology, mycology, and histo-pathology of the skin is given in the laboratories of the hospital.

At the Hospital for Sick Children, Great Ormond Street, special courses are conducted for from one to three months or longer, from October to July inclusive, for the purpose of keeping up to date the knowledge of children's diseases by practitioners both in general practice and in special studies. At Paddington Green Children's Hospital there is a course of post-graduate instruction in connexion with the Fellowship of Medicine.

At the National Hospital for the Paralyssed and Epileptic, Queen Square, post-graduate courses are held three times in the year—from January to March, April to June, and October to December—the duration of each course being about ten weeks; instruction is given in the anatomy, physiology, and pathology of the nervous system, in addition to clinical instruction of a comprehensive character. At the Hospital for Epilepsy and Paralysis, Maida Vale, no attempt has yet been made to give definite courses, but the amount of material at the hospital is stated to be sufficient to illustrate any particular branch of nervous work that post-graduate students may be interested in; at the present time the hospital co-operates with the Fellowship of Medicine and gives a "refresher" course of one week's duration. At the Royal National Orthopaedic Hospital the organization of special post-graduate teaching has long been in contemplation, but hitherto no systematic courses have been given, except that the hospital is taking part in the courses organized at various special hospitals by the Fellowship of Medicine.

In South-West London there has been a development of considerable importance for the post-graduate instruction is being carried on in a well-equipped municipal (formerly Poor Law) hospital in a suburban district, linked up with a neighbouring general hospital. A committee has been formed of representatives of the staff of the Bellingbrooke Hospital, the Wandsworth Division of the British Medical Association, and the South-West London Medical Society. Under the auspices of this committee a post-graduate association has been formed, affiliated with the Fellowship of Medicine, and courses of instruction are being conducted in connexion with the Bellingbrooke Hospital and the St. James's Municipal Hospital. The intention of this Association is to give the local general practitioners the opportunity of obtaining post-graduate instruction with the minimum loss of time, as all the work is carried out in the midst of the district. We are informed that classes on any special subject can be arranged, with a minimum of six members. Similar courses of instruction might be started with advantage by the consultant staffs of municipal hospitals in other suburban areas.

This summary of the post-graduate instruction provided in London at the present time is perhaps somewhat incomplete and inadequate, for not all the hospitals to which inquiries were sent have replied. But it contains information enough to show that there is a considerable supply of facilities in post-graduate instruction already in existence, and as it would seem that the establishment of a central post-graduate school and hospital must for a considerable time remain an unattainable ideal, fuller use might well be made of them.

THE late Mr. John Christopher Geiselbrecht has made munificent bequests to hospitals, including the following: £6,000 to the Star and Garter Hospital, Richmond; £4,000 to the Miller General Hospital, Greenwich; £2,000 to the Metropolitan Hospital, Kingsland Road; £1,000 each to the Samaritan Hospital for Women, City of London Dispensary, and the Queen's Hospital for Children, Hackney Road; £800 to the Paddington Hospital for Sick Children; £600 to the Eltham and Mottingham Cottage Hospital; £500 each to the Central London Throat, Nose, and Ear Hospital, Royal Hospital for Diseases of the Chest, City Road, Hospital for Women, Soho, French Hospital, Soho, Dreadnought Hospital for Seamen, and the British Hospital for Mothers of Babies; £400 each to the National Hospital for the Paralyssed and Epileptic, Evelina Hospital for Sick Children, Royal London Ophthalmic Hospital, and the Hospital for Sick Children, Great Ormond Street; and £200 to St. Peter's Hospital for Stone. He has also bequeathed 500 shares in the Alliance Assurance Company to the King Edward's Hospital Fund.

MOTOR NOTES FOR MEDICAL MEN.

BY H. MASSAC BUIST.

PROPOSED CHANGES IN THE LAW.

THE Departmental Committee on the Taxation and Regulation of Road Vehicles has been asked to take evidence on the taxation question raised in connexion with licences to use motor vehicles. In a few days the Budget is due to be introduced. Some motor owners, therefore, imagine that there will be an entire recasting of the scheme of motor taxation forthwith, because many of their organizations are seeking for a reversion to the fuel tax. It would, however, be impossible to recast all the arrangements within so short a space of time, even if it were possible, which it is not, to revert to a tax on fuel. The fact is that part of the Government programme is entirely a matter of placation. The issue will be the same as when the present law was going through the House of Commons. By reason of the numerous grounds on which a retention of the tax on fuel became impracticable, the Government of the day, not wishing to force on motor owners a method of taxation to which it was represented, they were opposed in the gross, invited an alternative proposition to the present style of tax in face of the impracticability of that on fuel. No motoring organization has ever accepted that invitation, simply because the alternative was a tax on tyres, and no motoring body dare suggest that this would be preferable to one on horse-power. If a man has bad luck in buying a tyre it would only aggravate his grievance if he had to pay an extra tax as well as the money with which to buy a substitute tyre. There may be modifications in the particular methods of levying the tax according to horse-power. For instance, there will be concessions in the Budget in regard to trade car licences. But there will not be any reversion to the fuel tax unless a miracle has happened since last the matter was gone into very thoroughly by the various Government departments concerned. The fact that, now that some of the motoring bodies, in an endeavour to get back to the fuel tax, are willing to concede that no rebates should be allowed makes no difference. Their chief cry, of course, is the Automobile Association's slogan concerning the current system, to the effect that it is "a tax on ownership, not on use."

The Tax on the Right to Use.

If we consider the matter historically, however, the slogan proves to be utterly worthless because, before this scheme of taxation came into operation two financial years ago, we had in force a system of taxation which takes us back to the earliest phase at which the motor movement really became a practical proposition—namely, eighteen years, when in January, 1904, there came into operation the Motor Car Act of 1903. This is still the law governing the movement in general, and as applied to taxation from 1904 onwards it was based on every owner paying a horse-power Treasury rating tax on his vehicle. Therefore there is nothing new in the principle of "a tax on ownership, not on use." Secondly, that slogan is a false expression of the fact, because the tax is not on ownership at all. A man can have any motor vehicle he likes stored in his motor-house and pay no tax on it. On the contrary, the tax is one levied on the right to use a car, and not on the ownership of it. In that sense a fuel tax is also a tax on the means to use a car, which is surely the same thing in practice as a tax on the right to use one. Besides, if we are to tax motoring at all, it must be on the right to use the given vehicle. If it were not so, we should have to run all round the country and tax everybody, because they might take a ride on a motor bus by paying a penny bus fare. This particular agitation has been purposely worked up. A large majority of members of the Automobile Association and Motor Union, which is the largest motoring body in the world, with a membership of over 150,000, has taken no notice of its referendum in spite of the great publicity given to the matter. Three weeks after it was out the Association was glad to announce that 35,000 returns had been made, which is not one in four. Even so, as was announced in these columns, it has been open to any member of the public who is a motorist, but who is not a member of the Association, to apply for such a form and fill it in.

The Problem of Clashing Interests.

Meantime the Second Interim Report of the Departmental Committee on the Regulation and Taxation of Road Vehicles has been issued, and is found to contain a vast number of

recommendations for embodiment in an Act which it is intended shall codify the various laws on the subject, and supersede our admittedly quite obsolete enactments governing road vehicle use. In considering the recommendations, however, it is advisable that the medical man should avoid the error into which, apparently, most commentators on the subject have fallen when they have assumed that because these recommendations are made they will, in fact, become law. The Committee has endeavoured to do its best on behalf of each of the many classes interested, with the result that a careful consideration of the document, as distinct from a single glance at such parts of it as concern any one section, will bring before the reader more clearly than any other means known to me the fact that at this stage there exists a large number of specialized motoring interests which deliberately clash with a large number of other specialized motoring interests. For instance, the regulations recommended for the encouragement of utility motoring are admitted by those concerned with that branch to be extremely generous, though a certain amount of resentment is expressed in those quarters at the suggestion that drivers of machines whose situation prevents them from hearing readily, or becoming aware of the presence of vehicles desirous of overtaking them, should be provided with mirrors and with sound-receiving devices, it being held by the complainants that this is putting yet an additional burden on the commercial vehicle user for the benefit of the private motorist. But the driver of the passenger car knows how necessary are these and sundry other recommendations. The various speeds at which it is suggested that large vehicles should be allowed to go would, if permitted by a future law, make a great difference in the conditions under which private vehicles will take the road in future. Motorists are more or less paying for the maintenance of the roads, yet a consideration of the classes of vehicles which are to be allowed on them, including some wherein the speed is restricted to 5 m.p.h., and which, progressing at such a speed, will take pieces out of any at present known road surface, are matters which, we may anticipate, will be debated hotly in the House. There are special recommendations to encourage trailers; also the use of pneumatic tyres for large vehicles, particularly of the passenger-carrying, motor-omnibus types up to 3½ tons. Machines so equipped are to be allowed to travel at a very lively turn of speed indeed, and that despite the fact that the air-filled tyre is at present frankly in the experimental stages. Some very ugly accidents have happened when one of these tyres has blown off the rim, or punctured, or become suddenly deflated through a tube being pinched when negotiating a turn, or what not. The story of the pneumatic tyre as applied to heavy vehicles in this country is one with a high percentage of disasters for miles travelled. Yet few would grumble at any endeavour of a Government department to produce a law that would be, if anything, a little ahead of the times in exchange for all our other motor laws that are years behind them.

One private motorist described the very generous regulations proposed in regard to the use of various classes of utility vehicles as "a doctor's benefit," by which he meant that, if such regulations came into operation at once, we should have a great increase in the number of road accidents. Curiously, the report states that the Committee has come to the conclusion that "there is no evidence at the present time that would justify prohibition or restriction of the use of left-hand vehicles in this country from the point of view of public safety." This is certainly a remarkable discovery after the findings and recommendations of coroners' inquests all over the country, many of them presided over by medical men; also of the mounting toll of accidents due to the use of left-side driven machines, which, in any case, have to be pulled too far out on their wrong side when a driver wishes to discover whether it is possible for him to overtake the vehicle ahead before it can be ascertained whether the way is quite clear. The left-side drive is a very awkward one in the case of the covered classes of utility vehicles, including light tradesmen's delivery vans and the larger sorts of lorries, to say nothing of the "heavy" used trailer fashion. Many of the suggested regulations in regard to trailers, alike as to speed and to their permissible length, making them virtually road trains, while being very convenient from the point of view of those who would transport their goods by this cheap means, are certainly calculated to add increasingly to the embarrassment, if not to the dangers, of road travel, and to the costs of road maintenance.

Obtaining Evidence in Defence of Charges.

As regards the use of passenger cars, the chief alteration proposed concerns the abolition of the speed limit and the substitution of prosecution on the grounds of dangerous, or otherwise undesirable, driving. The report points out frankly that the 20 miles an hour speed limit is a dead letter in practice. It also plainly indicates that there ought to be an end of the present 10 miles an hour speed limits in specified areas. The latter is a sound conclusion, especially in face of the now notorious, and in many cases, long since forgotten prejudicial influences which were instrumental in securing permission to establish a great number of the fixed speed limit areas about the country. It is recommended, instead, that in all areas where it is necessary drivers should be warned by signs as to how slow a maximum speed is advisable and, for the rest, that there should be prosecution for all undesirable driving.

As to the period within which a motorist may be proceeded against for alleged undesirable driving, it is proposed that there should be an increase of from 21 up to 28 days within which the police may serve a summons. But it is intended that this should be offset, in part, by desiring the police to give to an accused motorist earlier notice than the formal summons of the intention to prosecute. This, however, does not go far enough, because if proceedings are to be undertaken under the heading of undesirable driving, obviously they are far graver than the current and past series of prosecutions chiefly on the lines of infringing what is admitted to be a purely arbitrary and obsolete law—namely, the present speed limit of twenty miles an hour. It is therefore doubly important that reasonable facilities should be provided for the accused to gather evidence upon which to conduct his case. Obviously if a driver is not to be told at the time he is alleged to have offended, how is he to reconstruct the conditions of driving, especially as it is not recommended that it should be compulsory to advise a motorist until the actual moment of serving the summons. An interval of twenty-eight days after the event, or even two days, would often render it quite impossible to collect witnesses or to take photographs of road conditions obtaining at the given time, and so on. Certainly this part of the proposed changes will be subject to much debate—a point which was brought out at length, with the adduction of numerous instances, in these columns something like a year ago when the matter of the abolition or increase of the speed limit was under review.

Minor Recommendations.

A very important recommendation is that tampering with motor vehicles should hereafter be regarded as a criminal offence. The penalties proposed to be imposed in respect of offences against dangerous driving, and so on, are none too severe provided the conditions of prosecution are reasonable. At present the conditions proposed are not reasonable, either in face of the penalties or in face of any other penalties that might be substituted. A sufficient guarantee is not proposed to be afforded to the accused that he will have what is even a reasonable opportunity of making out his case, apart from which there is the common belief that in the police force promotion is sometimes related to the number of prosecutions secured. Therefore it is necessary that much greater safeguards than any suggested should be provided in this connexion. The recommendations in regard to doing away with certain red-tape details about taking out licences are excellent, as is that to the effect that the police should have regard to the object of this proposed law, as distinct from working according to the letter and against its spirit. Unfortunately a recommendation like the latter is rarely embodied in an Act. If it were, still it would depend entirely on the given bench being prejudiced one way or the other as to whether it would have any weight in practice. The regulations proposed in connexion with the overhang in utility vehicles show that there is no intention to make improvement in this connexion. It is suggested by the Committee that the police should have the power to test brakes. This is a proposal of doubtful value. On the one hand it would virtually make the police responsible for all vehicles taking the road with efficient brakes in good working order, and, on the other, might lead to most vexatious and tyre-destroying demonstrations to satisfy the police. In any case, much clearer regulations and more closely limited powers than are indicated would have to be laid down.

British Medical Journal.

SATURDAY, APRIL 29TH, 1922.

MEDICAL PERIODICALS.

MEDICAL journalism is the smallest of the medical specialities, but its followers probably come in for more candid criticism than those of any other; this is not surprising, since publicity is their aim, periodical publication is provocative, and every reader is clearly entitled to form his own opinion. Criticism may be favourable or unfavourable, but the former is seldom vocal, while the latter is commonly expressed with great vigour. Though the validity of the criticism is always weighed, as a rule no reply is or should be made: the final decision must be left to the arbitrament of time and the event. Now and again, however, the medical journalist is invited to state the grounds of the faith that is in him, and to set forth some of his difficulties. Such an occasion was recently afforded to Dr. George H. Simmons, editor of the *Journal of the American Medical Association*, when he was called on to give an address as President of the Institute of Medicine of Chicago. Very wisely he selected "Medical periodical literature" as his subject, since he could speak from "an acquaintance of nearly thirty years with medical journalism." In what follows we shall endeavour to give the chief points he made, since his observations may be read with interest even by those on this side of the Atlantic who feel that their withers are unwrung. At the same time it has to be admitted that the faults on which he expatiated are not wholly unknown here.

Dr. Simmons began by mentioning incidentally that in 1848, when Oliver Wendell Holmes was chairman of a committee of the American Medical Association on medical literature, the number of medical journals published in the United States was 20, that it had risen to 230 in 1903, and that it had since declined to 120, in spite of a remarkable increase in periodicals devoted solely to scientific medicine. Moreover, Dr. Simmons notes "a distinct change in the type of papers appearing in medical journals to-day as compared with twenty years ago. The therapeutic article of the past, replete with favourite prescriptions, often proprietary in character, has given way to scientific contributions on therapeutic methods, on pharmacology, on pathology, on etiology, on methods of diagnosis, on prophylaxis." Though the number of medical journals has decreased in America, it seems doubtful whether the volume of writing for publication has undergone any diminution, for the *Journal of the American Medical Association* is now receiving between fourteen and fifteen hundred manuscripts a year, exclusive of the papers submitted to the sections of the annual meeting. Dr. Simmons estimates that three-fifths of the manuscripts voluntarily offered are returned, and the greater part of his address was concerned with the reasons for rejection.

One reason is lack of space. A fair percentage of the papers were excellent both in matter and in manner of presentation, and there could be no doubt about them. Among other papers one that is informative, that presents new facts or practical information, if fairly well written, is not returned, though it may be necessary, with the author's help or approval, to shorten or revise. In this connexion the subject of length is raised; it, "like Einstein's theory as to space and time, is a matter of relativity. A paper of five hundred words may be long:

one of five thousand may be short." But undue length is a common fault, and Dr. Simmons finds three chief reasons for it. The first is "rambling," due to the absence of a plan, so that the author repeats himself and goes a long way round to reach a given point. Cross-headings are recommended, not only because in a paper more than a page or so long they encourage the reader, but because the task of introducing them reveals to the author defects in the logical arrangement of his matter. Next the difficulty many experience in making a beginning is touched upon. If the way to begin a paper is not immediately obvious Dr. Simmons recommends the perplexed author to "go right to the subject without preliminaries"; to begin in the middle if necessary; when the end is reached the difficulty of the beginning will usually have disappeared. Sharpey, the father of English physiology, was at pains to impress on his pupils the importance of learning how to report their results. His first injunction was to state conclusions at the beginning; this was the old plan of the university thesis, in composing which the candidate was required to set out at the beginning the proposition he intended to prove. The influence of Sharpey's teaching is still plainly to be traced in the writings of the chief English physiologists, though some of the lesser lights tend to lapse into presenting their readers with "protocols" of experiments related in laboratory slang. Dr. Simmons would have a long article begin with "a brief digest" to encourage the reader, and end with conclusions reflecting the author's premisses and deductions to help the abstractor. We may interject here that an abstractor who works on this system will often fail to do his duty by his readers.

The second cause of undue length is verbosity—a blemish which, Dr. Simmons admits, exists in the writings of most of us. It is to be remedied by revision; during that process the writer will be astonished to find how many words, phrases, clauses, sentences, and occasionally even paragraphs, can be erased without detriment to the meaning. Such deletions not only save space, but improve the style and help the reader.

The third fault enumerated is prolixity or diffuseness—the tedious discussion of non-essential details and the particularizing on trivialities. In an extreme form this fault is displayed by papers (of which it is said the *American Journal* receives specimens every week) in which the author who has a new fact or observation to make buries it in a mass of material which sometimes takes the form of a long historical introduction.

Dr. Simmons has a small opinion, as material for publication in a medical journal, of papers prepared for reading to a medical society; "as a rule, they are not so well thought out or as carefully written as are those prepared especially for printing." Some are composed to fill a vacancy, others are mere pot-boilers. Others, again, are designed to open discussions, and, while fulfilling that purpose, are not suitable for printing without drastic revision; they may be listened to out of courtesy or are carried through by the speaker's personality, but in cold type are not read. Certain societies founded recently in this country have made it a condition that the papers and discussions before them shall not be reported or printed, and from time to time older-established societies decide to put a veto on publication; this course has been taken lately by one of the sections of the Royal Society of Medicine. Were the reporting of meetings to become the exception and not the rule it would probably, by encouraging the tentative presentation of hypotheses and greater freedom of debate, be to the advantage both of medical societies and of the readers of medical journals.

The real remedy for the defects he sees—defects which, in spite of all that editorial staffs can do, continue to mar medical literature—is, in Dr. Simmons's opinion,

that the art of writing should be more carefully studied and all writings submitted to thorough revision. In support of this he quotes Sir Clifford Allbutt's method as described in his book *Notes on the Composition of Scientific Papers*. That book is, or should be, too well known in this country to make it necessary for us to quote from it; we will only recall that Sir Clifford's plan is first to jot down ideas and facts on slips of paper and sort them under headings; then to make a first draft and revise it; then a second and revise it; then a third and revise it; and then to put the whole away for at least a week "in order that the final reading may be done with refreshed attention." After an inspection of some of the manuscripts in the Osler Library, which is being catalogued in Oxford before its transfer to Montreal, Dr. Simmons is able to say that Sir William Osler worked in much the same way. He was able to trace one article through its various stages: first there were notes on odd bits of paper, evidently written at odd moments; then there was a rough outline of the paper in longhand; then the first typewritten copy, with interlineations, transpositions, and deletions; next the second typewritten copy, which had been considerably modified; and finally, the third typewritten copy, which had been given to the printer. If, Dr. Simmons pertinently asks, this is the method of the masters, "what about the rest of us?" He concludes his address with an apposite quotation from Barrie: "The man of science appears to be the only man who has something to say just now, and the only man who does not know how to say it."

A SMALL-POX EPIDEMIC ON THE GOLD COAST.

THE duties of a health officer in the outskirts of the empire are of necessity different from those of medical officers of health in the home country; opportunities are presented for the exercise of the best that is in a man in the way of initiative and individual responsibility. This is well illustrated by Dr. P. S. Selwyn-Clarke's monograph¹ on an epidemic of variola in a part of the world where the disease is endemic, and where its virulence to day resembles that of the pandemic which swept over Europe fifty years ago.

The epidemic, during which 300 cases occurred, affected Accra and the surrounding district on the Gold Coast. As regards native treatment of the disease, Dr. Selwyn-Clarke "frequently observed the attendants or friends of patients rupturing mature vesicles with the aid of a pointed stick." This is of curious interest. Rhazes for the same purpose used a needle of gold or silver, and in the Anglo-Saxon leech-book of the physician Bald, belonging to the tenth century, part of the treatment of the pox is to "delve away each one of them with a thorn." "Poccas" or "poc-adle" is definitely mentioned in Bald's second volume, and the late Dr. J. F. Payne was satisfied that this meant small-pox.² Rhazes and Bald flourished in the same century—one in Baghdad, the other in England, and it seems that after a thousand years their method of treating small-pox is practised on the Gold Coast in Africa. Statistics of 264 cases admitted to hospital are given by Dr. Selwyn-Clarke. Among them there were 68 deaths (25.7 per cent.), the average age at death being 26 years. Of the 68 "only one patient gave doubtful evidence of successful vaccination performed prior to being exposed to infection." Of the haemor-

rhagic type 14 cases were admitted, 8 of them purpura variolosa, and 6 of the haemorrhagic pustular. Only one of the 14 recovered. Of the admissions 199 cases (75 per cent.) were variola vera, made up of 125 confluent and 74 discrete. The fatality rate of the 199 was 27.6 per cent., of the confluent 37.6, and of the discrete 10.8. Of modified small-pox there were 51 cases, with no deaths.

The powers provided by the law for the control of infection in the Gold Coast Colony are in the form of ordinances and orders, including quarantine and vaccination ordinances. Notification became compulsory only when an area had been declared "infected" and a quarantine order applied. Hospital and contact accommodation was primitive, but was extended. Attention was given to the occurrence of aerial convection from the hospital, and the conclusion was reached that the balance of evidence on the whole negated the theory of aerial dissemination of the virus, but on the general question Dr. Selwyn-Clarke is of opinion that owing to risks of direct or mediate infection and inevitable leakages, the requirements of the Local Government Board in Britain as to sites should be carefully fulfilled.

As to vaccination, the total population of the affected area was about 55,000; only about 3,600 successful vaccinations had been performed during the two years 1918 and 1919, but in the epidemic year, 1920, the number mounted to nearly 70,000, the excess over the total population being explained by measures taken to deal with immigrant labourers and native passengers by sea. This was accomplished notwithstanding that the vaccination ordinance was not in force during the earlier part of 1920. Fearing an outbreak, Dr. Selwyn-Clarke set about training native sanitary inspectors in the art of vaccination. A useful system of passes for passengers was introduced, these being issued in the first instance only to persons who had had small-pox or been recently vaccinated, or were prepared to submit to immediate vaccination. To make the system effective all the roads were guarded by police posts, and to minimize inconvenience a public vaccinator was stationed at every police post. It is clear, in short, that the health officer exercised a benevolent despotism in fighting the disease and protecting against infection the population committed to his charge. Valuable information is given as to the vaccine material employed. Dried lymph in glass ampoules gave very disappointing results, so that its use was abandoned, but the suggestion is made that the defect may have consisted of acid impurity in the glycerin. Lanolinized vaccine lymph, prepared at Hayle, Cornwall, and sent out to the colony on ice, gave constantly good results when used shortly after its arrival, but deteriorated quickly on exposure to tropical heat, and the suggestion has been made that thermos flasks might be used where ice and ice chests are not available.

Dr. Selwyn-Clarke's report contains much interesting matter that cannot be touched on here, and he is to be congratulated, both on his management of the epidemic and the manner of his record.

INSPECTION OF EXAMINATIONS.

THE General Medical Council has just published a very important volume of reports on the Inspection of Examinations in 1920-21. The Council hopes that it may have a large circulation, and to this end has issued it at the very low price of 7s. 6d. (post free 8s. 6d.), though it contains 900 pages, and must in these days have been produced only at a much higher cost. Four inspectors were occupied in the work of visiting the examinations, Dr. Howard H. Tooth in Medicine, Sir Hector C. Cameron in Surgery, Sir William J. Smyly in Midwifery, and Dr. R. Bruce Low those for diplomas or degrees in Public Health. The volume contains a brief introductory report by the Council's Examination Committee

¹ *Small-pox in the Negro and Negeroid Tribes of British West Africa, with special reference to the Gold Coast Colony*. By P. S. Selwyn-Clarke, M.D., D.P.H. Cambridge, Medical Officer of Health, London: John Bale, Sons, and Danielsson.

² *English Medicine in the Anglo-Saxon Times*. By J. F. Payne, M.D. Oxford: Clarendon Press, 1901.

on the three final subjects of the curriculum—Medicine, Surgery, and Midwifery; a report by the Council's Public Health Committee on the inspection of the D.P.H. examinations; a general report on his own subject by each of the four inspectors, and also, in detail, a report on each individual examination visited by the inspectors; to these are appended the remarks of each body on the inspector's report on its own examination, and a copy of all the questions set at every examination. The volume will therefore serve the important purpose of showing to every teacher and examiner the lines followed by all the universities and licensing bodies in testing the fitness of candidates to receive the degrees or diplomas to which they aspire. Most examiners will probably admit to themselves the risk, in the preparation of questions, of getting more or less into a rut unless they keep a close eye on their own mental processes. The Council's publication provides them with a mine from which to dig new ideas for their own work; at the same time the character of the questions asked indicates the scope of the teaching given at the various schools. Indeed, it is difficult to see how any teacher or examiner who wishes to keep himself up to date can afford to be without this volume of Reports, and it was a good thought on the part of the Council to make it available to all concerned. The contents of the volume must, of course, have played an important part in the Council's draft schemes for revision of the whole teaching of the medical and public health sciences on which it is at present engaged. Its provisional recommendations have been sent to the licensing bodies and are now under their consideration. The Conjoint Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England has in fact issued provisional regulations to come into force on January 1st, 1923. They embody the details of the new medical curriculum, and will apply to all medical students who have not passed the required preliminary examination in general education before the first day of next year. They are provisional in the sense that the Royal Colleges reserve to themselves the right to revise them after the observations of the English Universities have been made public. The whole matter will be considered by the General Medical Council at its meeting in May.

HEALTH ORGANIZATION OF THE LEAGUE OF NATIONS.

An important branch of the work of the League of Nations is that of its health organization. The International Health Conference which was held in London in April, 1920, declared that the epidemic situation was menacing to all Europe, and that the task of fighting epidemics was beyond the strength of voluntary associations. The Conference urged, therefore, that the task should be entrusted to the League of Nations as the only official international organization with sufficient authority and power to undertake the work. In accordance with this recommendation an Epidemics Commission was set up by the Council of the League, and since the end of 1920 this Commission has co-operated with the Polish health authorities in their campaign against epidemics. The Commission, at the head of which was Dr. Norman White, formerly Sanitary Commissioner with the Government of India, had complete autonomy, but was responsible to the Council of the League. The funds placed at its disposal by the Governments which are members of the League were not large enough to make possible an anti-epidemic campaign on the scale originally planned, so the Commission began its work in Poland, and delivered to the Polish health authorities the motor transport, soap, clothing, medical stores, etc., most needed at the outset of the campaign; it also provided funds for the repair and equipment of bathing and disinfecting establishments, quarantine stations, and hospitals, and gave fifty complete fifty-bed hospital units. The work of this Commission was the first experiment in international sanitary co-operation on a large scale, and it has been a success. Last autumn, however, the epidemic situation in Russia, and the consequent

danger to her western neighbours, became greatly aggravated on account of the famine, and more drastic measures were found necessary to deal with the situation. An all-European anti-epidemic conference was therefore convened by Poland at Warsaw, with the approval of the Council of the League of Nations, and twenty-seven different nations took part. An account of the resolutions adopted was given in our last issue, at p. 653. It was notable as being the first general European conference in which Soviet Russia and Soviet Ukraine were represented. The Conference drew up a general report of the situation, and the lines were laid down for a series of sanitary conventions, which are now being negotiated between the States of central and eastern Europe as a first defence against epidemics. Finally, the Conference prepared a detailed plan for an anti-epidemic campaign in Russia and in the border States, and recommended that the conduct of this campaign should be entrusted to the League of Nations health organization and the Epidemics Commission. The Conference requested the Council of the League to transmit its recommendations to the Genoa Conference, on the ground that the latter was to deal with the economic reconstruction of Europe, and because an epidemic campaign in eastern Europe was in its opinion the indispensable preliminary to the work of economic reconstruction. It is hoped that the Genoa Conference will decide upon the measures to be taken with reference to the anti-epidemic campaign, and whether they shall be carried out by the health organization of the League of Nations. This health organization consists of, first, a committee appointed by the Council of the League, which acts as the executive body of the organization; second, the Office National d'Hygiène Publique in Paris, a body in existence before the war, which, though not a League organization, acts in close co-operation with the latter, and in practice serves as its general committee, drawing up draft conventions and laying down general lines of policy; third, a secretariat, which forms the health section of the Secretariat-General of the League. The Epidemics Commission—originally, as has been said, an independent body—is now also attached to the health section, and is therefore really a part of the health organization. An Epidemiological Intelligence Service has been organized to keep the health authorities of all nations informed as to the incidence of epidemic diseases, and a monthly bulletin is being issued containing statistics and charts of the incidence all over the world of cholera, typhus, dysentery, small-pox, and other infectious diseases. Another branch of the work of the health organization was the conference held in London in December, 1921, on the standardization of serums and serological tests, when, as reported at the time, a programme of inquiry and research was elaborated, to be carried out by the various laboratories and centralized in the Copenhagen Institute. The results will be examined at a forthcoming conference to be held at the Pasteur Institute in Paris.

A CORONER'S VERDICT.

We have again to call attention to an inquest which furnishes material for comment. An inquiry into the death of a boy of 5 years was held lately at Sandown, Isle of Wight, by the acting coroner in the island—a layman—and a report of the inquest appears in the *Isle of Wight Chronicle* of April 13th, 1922. The father's evidence was to the effect that the child had been suffering from occasional cough and swollen glands. Dr. G. B. Wood advised removal of the tonsils as soon as the child was in better health. Accordingly, on April 9th, Dr. Wood performed the operation, Dr. H. B. Billups gave the anaesthetic, and the district nurse assisted. In her evidence the nurse stated that Dr. Billups sounded the child's heart beforehand, and administered the anaesthetic by the usual method of a mask over the nose and mouth; the mask was taken away for removal of the left tonsil. After this the child showed signs of coming round, and anaesthesia was continued by nasal tube. During removal of the right tonsil the child turned blue, and Dr. Wood ceased the operation at once.

Blood was removed from the mouth and throat, and every effort made by artificial respiration to restore the child, but without success. In reply to the coroner, she said that she saw no reason at all why the operation should not be performed. Dr. Wood in his evidence described the case. The tonsils were much enlarged. On the day before the operation he examined the heart, and Dr. Billups did so next day. The anaesthetic consisted of three parts of ether and two of chloroform; the child took it very well. He had almost finished the operation when the child began to come to, and anaesthesia was continued by means of Junker's inhaler. Soon afterwards the child turned pale and the breathing seemed to stop; artificial respiration was at once begun, but there was no sign of recovery. The child was not under the anaesthetic more than ten minutes. Dr. Wood said that with the approval of the parents and the coroner he and Dr. Billups arranged for Dr. Horsburgh of Rydo to make a *post-mortem* examination; this showed that the child was suffering from a marked degree of status lymphaticus, and Dr. Horsburgh agreed that the cause of death was status lymphaticus. This evidence was confirmed by Dr. Billups, who described the precautions he took and explained that the condition could not be ascertained during life, though it was quite easy to do so after death. He added that Dr. Horsburgh said it was the largest thymus gland he had ever seen. The coroner's finding is reported as follows: "The Coroner said he felt great sympathy with the parents, and the case was a painful one so far as the doctors were concerned. He was afraid, however, that he could not go so far as the doctors in the opinions they had expressed. He thought the circumstances and justice would be met if he stated in his verdict that death was due to shock following an operation." It will be noted that Dr. Horsburgh and his colleagues appear from the newspaper reports to have been disposed to regard status lymphaticus alone as the cause of death, and it was presumably this view that the coroner found himself unable to accept when he said that he could not go as far as the doctors in the opinion they had expressed. While it seems clear that the operation could not be entirely excluded and must indeed be recognized as the immediate cause of death, we consider that the coroner would have been well advised to have included in his verdict a statement that the death was accelerated by status lymphaticus, in order to make quite clear that the medical men had been in no way at fault. The verdict, too, should have been one of misadventure. The circumstances connected with the making of the *post-mortem* examination appear to have been irregular, and we are of opinion that the coroner in this case should have ordered a *post-mortem* examination and should have called the medical man who made that *post-mortem* examination as a witness.

SCIENTIFIC SECTIONS AT THE GLASGOW ANNUAL MEETING.

THE officers of the Section of Anaesthetics at the forthcoming Annual Meeting of the British Medical Association in Glasgow have arranged the following programme: (1) A discussion on the broncho-pulmonary complications following operation under anaesthesia; (2) a paper and demonstration by Dr. A. L. Flemming on effects produced by exposing tissues to various concentrations of anaesthetic vapour; (3) demonstration of anaesthetic apparatus. The officers of the Section of Microbiology (including Bacteriology) have arranged the following provisional programme: (1) "The bacteriophage," by Dr. F. D'Herelle (Pasteur Institute, Paris) and Dr. F. W. Twort; (2) "The bacteriology of influenza," by Dr. Mervyn H. Gordon; (3) "Some similarities and dissimilarities in the microbiology of plant and animal diseases," by Professor V. H. Blackman; (4) "Mutation of species," by Dr. W. B. Brierley. Demonstrations will be arranged by Sir William Leishman, Professor Graham Kerr, and others. The officers of the Section of Anatomy have chosen the following preliminary list of subjects for discussion: (1) "The relation of the urethra to the vagina," by Professor J. C. Brash (Birmingham);

(2) "The naked-eye anatomy of the bone marrow, with age changes," by Mr. Piney (Birmingham); (3) "The teaching of anatomy by radiology in the anatomy department," by Dr. J. M. Woodburn Morison (Manchester); (4) "The problem of the structure of the vertebrate head," by Dr. W. B. Primrose (Glasgow); (5) A discussion on the administration of the Anatomy Act will be opened by Dr. Alexander Macphail, Dr. Adam Patrick (16, Buckingham Terrace, Glasgow, W.), one of the honorary secretaries of the Section of Medicine, asks us to say that he or his co-secretaries will be glad to hear of any members who might wish to submit short papers in the Section, in addition to having the names of any who desire to take part in discussions. In our issue of April 15th (p. 614) it was stated that the officers of the Section of Obstetrics and Gynaecology hoped to include Professor Kennedy among the speakers on "Stillbirth and pre-natal deaths." In order to prevent confusion it should be pointed out that this referred to Dr. A. M. Kennedy, of Cardiff, Professor of Medicine in the University of Wales, and not to Dr. Robert Kennedy, St. Mungo's Professor of Surgery in the University of Glasgow, and surgeon to the Glasgow Royal Infirmary. The names of the officers of the Scientific Sections were printed in the *STURTEWANT* of February 18th (p. 39). The meetings of the Sections will be held on Wednesday, Thursday, and Friday, July 26th, 27th, and 28th.

LIST OF SCIENTIFIC PERIODICALS.

MENTION was made a few months ago (January 14th, p. 71, of a scheme of the Conjoint Board of Scientific Societies to provide a world list of scientific periodical publications. The compilation of the list will be undertaken by the staff of the British Museum, and already material has been collected in the museum by various societies and by the Conjoint Board. We are informed that it is intended to include in the list medical journals in all branches which contain the results of original research. The list will give the titles of periodicals in existence on January 1st, 1920, or issued after that date in alphabetical order. The British Museum has no funds out of which to defray the cost of printing and publication, but it is hoped that a sufficient number of libraries will agree in advance to purchase one or more copies of the list at the price of two guineas each. The libraries in London, Oxford, Cambridge, Edinburgh, Dublin, and Aberystwyth, which take in such periodicals, will be indicated, and wherever possible at least one library in the United Kingdom will be mentioned for each periodical. As has already been mentioned, the need for such a list of periodicals devoted to tropical medicine was recognized some time ago by the British Medical Association, and Professor R. T. Leiper, Director of the Department of Helminthology at the London School of Tropical Medicine, undertook to supervise the compilation of a list showing all the libraries in London and some other centres in which a periodical can be consulted. The list will indicate how far the file of any periodical in any particular library is complete—a piece of information which will often save an investigator a great deal of time.

INTERNATIONAL CONGRESS OF OTOTOLOGY.

THE International Congress of Otology, as has already been announced, will be held on July 19th, 20th, and 21st, at the *Eco de Médecine*, Paris. The Congress will follow the annual meeting of the Société Française d'Oto-Rhino-Laryngologie, which will be held in Paris on July 17th and 18th, and the date originally fixed for the Congress has been altered so as not to clash with the Annual Meeting of the British Medical Association in Glasgow. The chairman and one of the secretaries of the British Organizing Committee of the Congress have paid a visit to Paris and were impressed with the anxiety of their French colleagues to make the Congress a success and to welcome a large number of English-speaking visitors. The subscription to the Congress is 100 fr. (£2 at present exchange), and cheques for this amount should be sent to the treasurer, Dr. G. Lanrens, 4, Avenue Hoche, Paris (8); those who intend to read papers or to join in the

debates should write direct to Dr. Hautant, 28, Rue Marbeuf, Paris (8^e). An exhibition of anatomical and pathological specimens (macroscopic and microscopic) illustrating diseases of the ear, nose, and throat is being organized, and particulars of the preparations for exhibition should be sent to Dr. P. Truffert, 2, Rue Ambroise Paré, Paris (10^e). It should be mentioned that lantern slides on the Continent are not of the square format, 8.2 cm. by 8.2 cm., but are what is called of the "international" size — namely, 8.5 cm. by 10 cm. The *Rapports* will be printed and circulated before the Congress to every member who has paid his subscription. A ladies' committee is being organized in Paris, with Madame Hautant as chairman, and among others she will be assisted by Mesdames Robinson, Jarvis, and Gross, who are the wives of English and American medical men settled in Paris, and are all fluent linguists. The corresponding member in London of the committee is Mrs. Lionel Colledge, 36, Belsize Grove, London, N.W.3. Tentative arrangements have been made, for those who intend to attend the Congress, at the Hotel St. James and Albany, 211, Rue St. Honoré; this hotel is situated centrally, and a room will be put at the disposal of members of the Congress whose notices can be posted and appointments arranged. Any further information may be had from either of the honorary secretaries, Mr. Lionel Colledge, 22, Queen Anne Street, London, and Mr. J. S. Fraser, 50, Melville Street, Edinburgh.

A NATIONAL COUNCIL FOR MENTAL HYGIENE.

WE may recall that the meeting at which it is proposed to form a National Council for Mental Hygiene will be held on Thursday next, May 4th, at the house of the Royal Society of Medicine. The purpose the founders of the Council have in view was explained by Sir Courtauld Thomson in a letter published in our columns of April 1st (p. 533). The letter pointed out that the recent establishment of a few hospitals and clinics for the treatment of "functional nervous disorders," which might be more scientifically labelled "minor disorders of the mind," affords evidence of the fact that the early recognition and treatment of these maladies is generally regarded as a matter of importance, and went on to state that many societies and associations, old and young, are engaged in promoting the study of mental disorders, the welfare of the insane, the problems of industrial psychology, and the various aspects of mental deficiency. The hope of the founders of the National Council for Mental Hygiene is that it may be a central organization encouraging these institutions and societies to expand and to add to their usefulness by organized co-operation. The meeting on May 4th will decide on the constitution of the Council, will elect officers, and carry out other business. The chair will be taken by Sir Courtauld Thomson at 5 p.m., and the speakers will include Sir Humphry Rolleston, K.C.B., President of the Royal College of Physicians of London, Dr. Henry Head, F.R.S., Sir Leslie Scott, K.C., M.P., Lieut.-General Sir John Goodwin, K.C.B., and Sir Maurice Craig, C.B.E.

LETHARGIC ENCEPHALITIS.

ACUTE epidemic encephalitis (lethargic encephalitis)¹ was the subject chosen for intensive discussion at its first meeting on December 28th and 29th, 1920, at New York City by the Association for Research in Nervous and Mental Diseases. The information thus brought together by thirty-five contributors is now presented in a rather novel form: instead of printing each contributor's paper in full, each contributor is credited with the facts that he has established, but duplication of reports has been avoided; in addition the discussions of various problems by question and answer are printed in a way somewhat suggesting that of proceedings in a court of law. The considerable task of editing has been discharged by a committee of fifteen, prominent among whom are

¹ *Acute Epidemic Encephalitis (Lethargic Encephalitis)*. An investigation by the Association for Research in Nervous and Mental Diseases. Report of papers and discussions at the meeting of the Association, December 28th and 29th, 1920. New York: Paul B. Hoeber, 1921. (Pp. xxii+258; 36 figures. 2.50 do's.)

Drs. C. L. Dana, F. Tilney, and Foster Kennedy. The introduction to the volume consists of Dr. W. Timme's presidential address at the meeting, and sets out the aims and working methods of this new American Association for Research in Nervous and Mental Diseases — namely, to co-ordinate efforts in one direction at a time, so that all the available data bearing on the disease under investigation can be collected and analysed according to a well-thought-out scheme; it thus recalls the collective investigation of the eighties in this country, in the origination of which the late Sir George Humphry took such a prominent part. The result of this method as applied to acute epidemic encephalitis is now shown in a mass of material, valuable for reference, dealing with the history, etiology, morbid anatomy, pathology, symptoms, diagnosis, and prognosis. Each section contains the final conclusions arrived at, and these are careful and well considered. As regards the etiology, pathogenesis, and incidence it is not yet possible to form final conclusions. The consideration of the symptoms occupies about half the volume, and is divided into three sections devoted respectively to those referable to the brain, to the spinal cord and peripheral nerves, and the psychotic manifestations. The diagnosis between lethargic encephalitis and acute poliomyelitis, especially when the diseases are fruste or atypical, may be impossible, and in the absence of knowledge as to the nature of the responsible agent the committee did not feel able to report upon the merits of any particular method of combating the disease. The concluding chapters on the morbid anatomy and on the bacteriology, experimental pathology, pathogenesis, and immunology of the disease are well illustrated. Finally, there is a useful bibliography.

POST-GRADUATE LECTURES AND COURSES IN LONDON.

THE first of the series of lectures recently arranged by the Fellowship of Medicine will be given at the house of the Royal Society of Medicine, 1, Wimpole Street, on Monday next, May 1st, at 5 p.m., by Sir Humphry Rolleston, K.C.B., on "Recent physiology of the liver and its application in practice." Particulars as to other lectures were published on April 15th (p. 615), and it was at the same time stated that a special post-graduate course in general medicine had been arranged to be held at various hospitals in London from May 1st to 13th. Copies of the complete programme of lectures and the syllabus of the special course will be forwarded on application to the Secretary of the Fellowship, 1, Wimpole Street, W.1. The fee for the post-graduate course is five guineas; the lectures are open free to all members of the medical profession.

SIR HUMPHRY ROLLESTON has accepted an invitation of the Council of St. John's College, Cambridge, to give the next *Linacre* lecture on May 6th, 1922. The subject he has selected is "Medical Aspects of Old Age."

TWO Hunterian lectures on the results and treatment of gunshot wounds of the blood vessels will be delivered in the theatre of the Royal College of Surgeons of England, Lincoln's Inn Fields, by Professor Harold Burrows, C.B.E., F.R.C.S., on Wednesday and Thursday, May 10th and 11th, at 5 o'clock.

PROFESSOR E. MELLANBY, M.D., will deliver the Oliver Sharpey lectures before the Royal College of Physicians of London on Tuesday and Thursday, May 2nd and 4th. The lectures will be given at 5 o'clock, at the College, Pall Mall East; the subject is, "Some common defects of diet and their pathological significance."

THE Association of Surgeons of Great Britain and Ireland will meet in Leeds on May 4th under the presidency of Sir Berkeley Moynihan, who will open a discussion on gall stones, their complications and the treatment which should be adopted. Among the subjects to be considered on May 5th are the surgery of the parathyroids and of tuberculous disease of the spine.

India.

KASHMIR MISSION HOSPITAL.

THE report of the Kashmir medical mission of the Church Missionary Society for 1921 states that there were during the year 12,133 new out-patients, with a total attendance of 25,670. There were 1,706 in-patients in the hospital and 3,785 surgical operations were performed, including 774 major operations. The medical superintendent records that enteric fever was very prevalent last year, especially in the city of Srinagar, and more cases of enteric fever were admitted to hospital than in any previous year; owing to the insanitary habits of the people of the city it is extremely difficult to cope with this disease. A special appeal is being made for funds to bring the present electrical appliances up to date, and it is estimated that £250 will be required. The hospital's financial revenue for the year is the largest that has ever been received, totalling 50,000 rupees; the largest item, that of fees, amounted to 17,000 rupees; the deficit of the previous year was wiped out, and a balance of over 8,000 rupees has been carried forward. During the year the Viceroy and Lady Reading visited the hospital and expressed their admiration of the work carried on. In regard to the Leper Hospital, during the year 113 new cases were admitted, making a total of 216 patients. The new treatment by ethyl esters was begun, and so far seven cases were treated; a dose of 1 c.cm. was given to commence with, which has been increased to 2 c.cm. (5 c.cm. being the maximum dose); the cases are showing signs of improvement. Sodium gynocardate, it is stated, is being given to 20 cases by month, but without apparent benefit. The hope was expressed that the State would adopt measures for the compulsory segregation of lepers in Kashmir, by which means alone leprosy could be stamped out in that country. The entire cost of the upkeep of the Leper Hospital is borne by the Kashmir State. The superintendent of the Mission Hospital and honorary superintendent of the Leper Hospital is Dr. H. T. Holland.

THE GENERAL MEDICAL COUNCIL DELEGATE TO INDIA.

Dr. Norman Walker has completed his tour of Bombay, Lahore, Delhi, Lucknow, Amritsar, and Agra, and whilst at Delhi addressed a small gathering of members of the Legislative Assembly and explained that the mission entrusted to him by Mr. Montagu (the late Secretary of State for India) was to ascertain how the Indian medical student could be given the same status with the British Medical Council as that of students in all other parts of the world.

MALARIA IN BOMBAY.

"It is with a real sense of alarm that the community have viewed the enormous increase of malaria in Bombay within the past nine months. . . ." On this text forty-five British and Indian firms and heads of establishments in the Fort have addressed an urgent letter to the Bombay Municipality. They complain of the large numbers of malaria mosquitos infesting their store rooms, godowns, and other premises, and declare their conviction that "unless some very stringent measures are adopted by the Municipality with the close co-operation of the residents of this city," more especially those living in the specially infected Fort area, the effect of the scourge "will have a most disastrous influence upon all living in Bombay." The letter emphasizes that its signatories are not only considering the deaths that malaria causes, but also the prevalence of non-fatal malaria attacks.

ALL-INDIA AMBULANCE COMPETITION.

Owing to the railway strike, and the fact that in present conditions many railway, police, and military teams have found it impossible to attend, it has been necessary to cancel the All-India Ambulance meeting this year. It is hoped to hold it next year at Allahabad, at the end of January or beginning of February.

INFANT MORTALITY IN INDIA.

The Countess of Dufferin's Fund has placed at the disposal of the Local Governments of Bombay and Bengal respectively the services of Dr. Florence Barnes and Dr. Dagmar Curjel for the purpose of making an inquiry into the conditions of women industrial workers during childbirth. The inquiry will take about a year, and it is believed that many

facts will be elicited which will be of great service in reducing maternal and infant mortality in all classes of life and in all parts of India.

INDIAN MEDICAL SCHOOLS.

An appeal is being made for the funds of the Lady Hardinge Medical College, and the opportunity is taken to draw attention to the special features of this institution. The College is devoted to the medical education of the women of India, and draws women from all parts of India, not excluding the distant Presidency of Madras, and also from the States of the ruling princes and chiefs of India. —One of the last official acts performed by Lord Ronaldshay as Governor of Bengal was the opening of the Ronaldshay Medical School, the foundation stone of which he laid nearly two years ago at Burdwan. The School owes its existence to the generosity of the Maharajahdhiraja Bahadur.

England and Wales.

ORTHOPAEDIC SURGERY AT THE LEEDS GENERAL INFIRMARY.

FOR some years the formation of an orthopaedic department at the Leeds Infirmary has been under the consideration of the Board and the Faculty. It will be remembered that during the latter years of the war the Second Northern General Hospital at Beckett's Park, Leeds, was converted into an orthopaedic centre, and the large experience which was in this way brought before the surgeons of Leeds and of those others who were associated with them in the work has undoubtedly acted as a stimulus to the formation of a new department for the treatment of deformities and other conditions calling for orthopaedic treatment. The new department is to be under the control of Mr. S. W. Daw, who has been assistant surgeon to the infirmary since the year 1913; so far as the infirmary is concerned Mr. Daw's work will be confined to the orthopaedic department. As it was determined that the transference to the special department of one member of the surgical staff should not alter the number of surgeons, this has led to a vacancy on the assistant surgical staff, which will be filled in due course. The formation of the department calls for the appointment of two additional residents, a resident orthopaedic officer and an orthopaedic house-surgeon; the former will be paid a salary of £150, and will rank with the other senior residents; the latter will rank with the other house physicians and surgeons. The out-patient department will, in the first instance, be open on Tuesdays at 10 a.m., and this will provide the usual access for all cases which are not of an urgent character. Operations of a non-urgent character will be performed on Saturdays at 10 a.m. The scope of the department has been very carefully discussed by the Faculty and a general understanding arrived at, but it is fully grasped that this may require reconsideration at a later date. In the meantime, also, eight male beds and four female beds have been allotted to the department for the treatment of cases other than fractures. The number of beds which will be required for fractures is uncertain, but the fracture cases are to be segregated and placed under the care of the officer in charge of the department. A certain number of cots will also be allotted to the department, and the officer in charge will share with the other members of the surgical staff the beds in the two semi-convalescent hospitals at Cookridge which are at their disposal.

It has also been arranged that the medical side of the house shall be intimately associated with the work, and especially with the after-treatment. This will be given effect to by the association with the department of one or more members of the medical staff who will exercise supervision over the departments of massage, electrotherapy, and physiotherapy. It is hoped that in the near future a Lectureship in Orthopaedic Surgery will be established at the University, and that a School of Massage will develop in connexion with the department, nor is the hope a vain one that it may not be long before curative workshops may arise somewhere in Leeds which shall be under the control of the department. The development of the department will be watched with sympathetic interest by all who are concerned in hospital work, and most of all by Mr. Daw's immediate colleagues, who rejoice to see him provided with work for which he has a special aptitude. It is interesting to recall with what enthusiasm the early work of Ogston and Macewenpton genu valgum was followed in Leeds; Mr. Pridgin Teale, Mr.

Jessop, and very notably the late Mr. McGill were ardent disciples of these two men in their capacity of orthopaedic surgeons. The writer of these lines well remembers the admiration which he heard expressed of the work of these two men, both happily with us still, when first he went to Leeds in 1883. He also remembers quoting in their hearing the teaching of Ogston, and his discussion of the merits of the two operations. It will be remembered that Ogston's was the earlier operation, and that it even now appears the more scientific as aiming at the removal of the essential deformity, while that of Macewen savoured rather of making a deformity to neutralize that which already existed—at least this was how it appeared to the students. Ogston used to tell his students that he thought he got as good results by one operation as by the other; but with characteristic honesty he used to point out that one of the operations was his own, and he used to advise that the operation of Macewen should be adopted as being the better of the two. There must be many old Leeds students who will almost *hear* Mr. Jessop's comment: "That showed the greatness of the man," as indeed it did.

In this scheme the teaching of the students has received careful consideration; all students will serve for some time in the department, will receive more careful training in the management of recent fractures, and will be enabled to follow the after-treatment under more favourable conditions than have hitherto prevailed.

MEDICAL ARRANGEMENTS IN BIRMINGHAM.

The Faculty of Medicine of the University of Birmingham has arranged a unique and important post-graduate course of lectures and demonstrations on "Crime and punishment," commencing on Monday, May 15th. The course is a comprehensive one and includes "Mental defect," "Insanity," and two special lectures by Dr. Maurice Nicoll, the lecturer for the year to the university in psychotherapy, the subject being considered in all its aspects. The work will occupy the greater part of each day from the beginning to the final day of the series on Friday, May 26th. The course is of exceptional interest in so far as it is not wholly theoretical, a considerable proportion of the available time being devoted to practical demonstration. A leaflet containing detailed information can be obtained on application to the Dean of the Medical Faculty.

The Ingleby lectures will be delivered this year, on May 17th and 24th, by Professor James Russell, the subject being "Clinical studies in some of the albuminurias of childhood, with special reference to orthostatic albuminuria." The lectures commence at 4 o'clock in the Medical Lecture Theatre in the Edmund Street Buildings of the University.

THE MANCHESTER RADIOLOGICAL DEPARTMENT.

Important additions have been made possible at the radiological department of Manchester Royal Infirmary by the generosity of Mr. Robert McDougall, who has given £5,000 to be spent entirely at the discretion of the infirmary's authorities, in memory of his father, the late Mr. Arthur McDougall, a member of a well-known Manchester firm of flour-millers. This is the second time within a year that the department of radiology has been fortunate in receiving important donations, £4,000 having been given recently by an anonymous donor for research work.

Scotland.

LISTER WARD AT GLASGOW ROYAL INFIRMARY.

In the *Glasgow Herald* of April 18th there appears above the signature of Mr. James A. Morris an eloquent plea for the retention of the Lister ward in the Glasgow Royal Infirmary. He says that while Glasgow has raised herself from a very ancient but commercially unimportant township to one of the greatest seaports of the world, yet she has ever been pertinaciously blind to that form of enlightenment which finds expression in veneration of the memorials of her past. That this spirit should still circumscribe her mentality is the more extraordinary because Glasgow is not and never has been a city without leaders in refinement. Her ancient university and its ripe scholarship are not unknown; and in art has not one of the most vital and pregnant schools of modern Europe, painting taken its name from the city? Moreover, which are ever the more enduring, her *words*! Glasgow flourish by the preaching of the Word," indicates at least a one-time spiritual

aspiration; while in the world realms of medical research and surgical achievement Lister's name stands pre-eminent. Yet because of the purely material and evanescent she has in her ancient architectural monuments, as in the preservation of the shrines of the spirit, deliberately turned her back on the altitudes of life, if only she may thereby and for the moment grasp a temporary relief and ephemeral convenience by the destruction of some irreplaceable landmark or shrine. Of her ancient buildings all save the Cathedral, Provand's Lordship, and the Tolbooth steeple have gone irretrievably; but even of those remaining the Cathedral, and in lesser degree the Tolbooth steeple, have suffered sore mishandling from the spiritual forebears of those who would to-day destroy the Lister ward. It will afford matter for a curious homily upon Glasgow if, with all her wealth of heart, her powerful brain and inexhaustible vitality, she yet in her blindness destroys a shrine that in Paris, Vienna, or Rome would be held as above rubies.

SCOTTISH WESTERN ASYLUMS' RESEARCH INSTITUTE.

In the annual report for 1921 of the Scottish Western Asylums' Research Institute, the director of the laboratory, Dr. W. Whitelaw, states that 470 specimens were examined from the associated asylums, including 220 Wassermann reactions in bloods, 50 cerebro-spinal fluid examinations, and 200 other examinations. During the year he had continued the investigation of groups of cases of insanity by inquiring into the possibility of there being any sources of infections. He was especially interested in the possibility of demonstrating that organisms isolated from foci of the teeth, tonsils, stomach, and bowels might be infecting agents; the results so far have been disappointing. Dr. Whitelaw stated that he hoped to get some of the assistant physicians in the associated asylums to co-operate with him in this work.

HEALTH OF PERTH.

In the annual report of the medical officer of health of Perth for 1921, Dr. C. Parker Stewart records that the mortality for the past year was 14.7 per 1,000, a figure which was one of the lowest on record; the mortality from tuberculosis was the lowest on record, the decline in that disease being from 2 per 1,000 in 1900 to 0.7 in 1921. The birth rate for the year was 19.4 per 1,000, as compared with 22 in 1920 and 28.1 in 1899.

Correspondence.

GASTRO-JEJUNOSTOMY FOR PERFORATED GASTRIC AND DUODENAL ULCER.

SIR,—Mr. Southam, in his paper of April 8th, on the treatment of perforated gastric and duodenal ulcer, raises the question, Should an immediate gastro-enterostomy be performed? It is an important point, inasmuch as perforation is a surgical abdominal emergency, in which frequently severe shock is already present before operation, and in which, therefore, no unnecessary prolongation of the operation is justified. It would be instructive to hear the opinions of acknowledged masters of stomach surgery on this point.

Mr. Southam, following up his cases with the assistance of the radiologist, states that 90 per cent. required no further operative treatment. I may say that many years ago, long before stomachs were examined by the x-rays, either before or after operation, I came to the conclusion that for the majority of patients who perforate have no further symptoms of gastric or duodenal ulcer. I stumbled upon this quite accidentally. I used to perform gastro-jejunostomy (and in those days it was considered the panacea for gastric ulcer) as part of the routine for perforation. But I came across cases who were so ill at the time of operation that I was afraid to prolong it after closing the perforation, and so closed the abdomen with the intention of performing the anastomosis a few weeks later. But, to my surprise, I found nearly all of these patients complained of no symptoms whatever on recovery from the simple closure of the perforation. I used to keep these patients under observation for months, but symptoms almost never appeared. I was hereby led to abandon gastro-jejunostomy as part of the routine operation for perforation, and only to adopt it in those cases where symptoms persisted or recurred. These formed a very small minority. It may be said that symptoms may have recurred later, after the patients had passed out of observation, and that they may have fallen into other hands. I do not think this likely. Any patient who has perforated and come through

the operation for it knows more or less that his life has been saved, and would almost inevitably return to the surgeon he supposed had saved his life if at any future date he required treatment for symptoms which he knew preceded his former catastrophe. Further, patients who have been finally discharged have always been told to report themselves immediately for any symptoms of "indigestion"; a few, but only a few, have done so.

I am convinced, explain it how one may, that far the majority of patients who have perforations simply closed are cured finally of their ulcers. If that is so the correct treatment would seem to be to suture only at the time of perforation, reserving for further operation those patients who show evidence, clinical or radiographic, or both, that their ulcers have not healed. It will then be found that nearly all of them require no further surgical treatment.—I am, etc.,

Portsmouth, April 17th.

CHARLES P. CHILDE, F.R.C.S.

DRAINAGE IN ABDOMINAL EMERGENCIES.

SIR,—Miss A. Chmrehill's paper (BRITISH MEDICAL JOURNAL, April 15th, p. 591) raises most important questions on abdominal drainage. It is interesting and instructive to hear the opinions of junior surgeons who do the bulk of hospital emergencies, and whose daily routine is made up of such cases. More particularly is the question of drainage vital in regard to nento conditions of the appendix. Whether a tube or other drain be introduced into the pelvis in a case of ruptured gastric or duodenal ulcer (and I do not think any other drainage is now thought of in such cases) has but little influence on prognosis. At most it is only kept in for twenty-four hours, allows the immediate escape of a possibly infected material, never prolongs healing, and does not produce faecal fistula, intestinal obstruction, or cause any serious damage whatsoever.

With appendicitis it is otherwise. Drainage is often, I imagine, the deciding factor between life and death, or, alternatively, between a convalescence of three weeks and one of double or treble this period. If some rules could be laid down for the general guidance of surgeons, they would be helpful, though it would have to be conceded that each case must be considered and treated on its merits.

Tentatively and with due humility I would suggest—

1. That no drainage is necessary where the appendix is unruptured.
2. Where rupture occurs during removal of the appendix drainage is unnecessary.
3. It is not necessary to drain an appendix abscess which is completely surrounded by omentum.
4. In third-day cases, or in those of shorter duration, where the appendix is ruptured, but the appendix and the extravasated material are completely intraperitoneal, it is unnecessary to drain.
5. Where there is a plentiful flow of peritoneal fluid, and where, without damage to the abdominal contents, the infected material, including concretions, can be easily mopped out, no drainage need be employed, even in cases of a duration longer than forty-eight hours.

On the other hand, drainage should be adopted—

1. Where there is general peritoneal infection, as distinct from peritoneal inflammation. Infection will be indicated by the absence of walling off, by a scanty peritoneal fluid, by general intestinal distension, and by the odour characteristic of *Bacillus coli* before the region of the ruptured appendix is reached. A plentiful outpouring of peritoneal fluid, on the other hand, is a favourable omen, and is strong evidence for complete closure of the peritoneum.
2. Where in late cases there is a localized abscess with rigid walls and the appendix is not removed. In such cases an attempt should be made to open directly into the abscess.
3. Where the appendix is truly retroperitoneal and ruptured, and a considerable area of cellular tissue usually behind the caecum is soiled.

Three other points may be added:

1. Drainage tube or rubber dam drain should attain its object by the shortest intraperitoneal route. If a portion of it must lie within the peritoneal cavity it should lie along the parietes and never be completely surrounded by gut.
2. In purulent cases it is difficult to protect the wound adequately, and healing is but little prolonged and is often much hastened by a rubber dam drainage of the wound itself.
3. No antiseptics other than ether should be introduced

within the abdomen, more especially if the peritoneum is to be completely closed.

—I am, etc.,

Belfast, April 15th.

S. T. IRWIN.

ROUTINE PELVIMETRY IN ANTE-NATAL CASES.

SIR,—I have read with interest Dr. Thorne Thorne's letter of March 25th and Dr. Foss's criticism of that letter of April 8th.

I quite agree with Dr. Thorne Thorne that routine pelvimetry in ante-natal cases, especially in primiparae or in multiparae giving a history of previous difficult labours, is absolutely essential to good midwifery.

At the same time I think with Dr. Foss that Dr. Thorne Thorne might go somewhat further and take the other external diameters of the pelvis, as well as the external conjugate and diagonal conjugate. Marked shortening of the external conjugate is certainly a sign that the true conjugate is diminished.

But, to quote from a very excellent book called *Midwifery by Ten Teachers*, the ten teachers being the present lecturers on the subject at the ten medical schools of the larger London hospitals—

"The external conjugate is supposed to be 3½ inches longer than the true conjugate; but this is not exact, as the thickness of the bones and subcutaneous tissues varies so much. Hence it is only a rough guide; if it is over 7½ inches the true conjugate is probably not shortened, if less than 7 inches the true conjugate probably is shortened."

Again, the same authorities state that—

"External pelvimetry is of value because the size of the internal measurements can be more or less accurately deduced from it, generally *less* rather than *more*, but *chiefly* because it indicates the *type* of contracted pelvis present."

That, I think, is the weak point of merely taking the external conjugate, for if that is found to be shortened it gives no information as to whether a generally contracted or a flat rachitic pelvis or any other type of contraction is present. In a flattened pelvis typical measurements would be—intercristal 11 in., interspinous 11 in., external conjugate 6 in., against the normal 11, 10, and 7½ in., the iliac bones in this type of contraction being everted and flared out so that the anterior superior spines come to lie in the same line or even external to the line of the iliac crests.

In a generally contracted pelvis all the diameters are dwarfed, and typical measurements would be intercristal 9½ in., interspinous 8 in., and external conjugate 6 in.

In both these cases the external conjugate is the same, and yet the type of contraction, the mechanism of delivery, if effected *per vias naturales*, the prognosis as regards the mother and the child, and the management and treatment of the case, are essentially different.

To quote the same authorities—

"A conjugate of 3½ inches in a generally contracted pelvis may be considered for purposes of treatment as being equivalent to a conjugate of 3½ inches in a flattened pelvis."

In a flattened pelvis, incarceration of the gravid uterus, malpresentation, prolapse of the cord, denting of the cranial bones, early rupture of the membranes, etc., are common. In a generally contracted pelvis these complications are rare.

Again, in minor degrees of flattened pelvis, podalic version is sometimes indicated as an alternative to the forceps. A generally contracted pelvis, however, is a positive contra-indication to podalic version.

It is therefore, in my opinion, very important to know exactly what type of contracted pelvis one is dealing with, and this cannot be done by relying solely on the external conjugate measurement.—I am, etc.,

Chislehurst, April 15th.

H. GRAHAM-HODGSON.

SIR,—I must beg a little more of your space to reply to Dr. Thorne Thorne's letter in the JOURNAL of April 15th, in which he asks for my authority—other than my own experience, which he deems inadequate—for my assertion that I regard the external conjugate as fallacious.

I venture to quote the following from *Midwifery by Ten Teachers* (Comyns Berkeley, Russell Andrews, J. Fairbairn, etc.):

"The fact that the external conjugate diameter is a little more or less than normal is of no import owing to the difficulty which at times is experienced in measuring it on account of the soft parts covering the spine of the last lumbar vertebra, . . . it is only a rough guide."

This is ancient history—1917. I therefore quote from the *Encyclopædia of Midwifery and Diseases of Women*, 1921 (section by A. W. Russell):

"External conjugate is taken, etc., . . . measures about 8 inches, but is so variable even in ordinary conditions that it is not reliable. . . ."

I am sorry that Dr. Thorne Thorne has so much difficulty in determining the diagonal conjugate and thence the true conjugate. My first authority says:

"The internal diameters are of the utmost importance . . . if the pelvis is larger than normal the fingers will not reach it (the sacral promontory), but if at all contracted the promontory should be easily palpable."

If Dr. Thorne Thorne will admit my experience as evidence, I must say that I found this so during an extensive course in an ante-natal clinic in London.—I am, etc.,
R. STAFFORD FOSS.
Woking, April 16th.

SIR,—I was very interested indeed in Dr. Thorne Thorne's letter on the above subject. The question of routine is an important one; its efficiency will mean that many abnormalities are diagnosed and treated at an early date, which if left to the last moment might be a much graver source of danger to the patient and anxiety to her physician.

Apparently opinions differ as to the reliability of the different measurements, but it would seem that this operation of external pelvimetry is one that it is well worth adopting as a routine, for (1) the measurements may suggest a contracted pelvis, or (2) in the process of measuring some abnormal condition that otherwise might have escaped notice may be recognized.

If the slightest doubt exist that the pelvis be not normal then I think it is well to think of the internal measurements and the probable course of the case as indicated by them.—I am, etc.,
R. E. TOTTENHAM.
Dublin, April 17th.

THE WORK OF SIR PATRICK MANSON.

SIR,—Patrick Manson was a great man who, with Laveran, Golgi, and Bruce, flung wide the gates of parasitology for tropical medicine to enter. Your obituary of him to-day is a warm but temperate eulogy, and a good history of his career; but there are some elements in it which may lead to confusion among any who consult it for future biographical purposes; and I should like, with your permission, to discuss them, if only for the sake of a book which I am now completing. The points are as follows:

In the *Lancet*, January 12th, 1878, Cobbold mentioned a suggestion of Bancroft made to him on April 20th, 1877, previously, that the embryos of *Filaria bancrofti* may be carried by mosquitos. Between these dates Manson appears to have proved the point, at least partially. Where did the suggestion originally emanate?

At the beginning of his fourth paragraph your biographer seems to suggest that this work of Manson's was the first case in which "the transmission of an agent of disease by intermediary agents" was ever proved to occur. Surely many cases had been previously proved by older parasitologists; and the life-cycle of *F. bancrofti* in mosquitos (so far as Manson had then determined it) appears to be largely the counterpart of that of *F. medinensis* in *Cyclops* as found by Fedtschenko on Leuckart's suggestion many years previously. I believe that Manson knew of Fedtschenko's work when he commenced his own.

Does your biographer do full justice to Manson's admirable studies on the pathogenesis of the numerous and various lesions of filariasis?

Until 1897 both Manson and I thought that mosquitos live for only four or five days after feeding—a mistake which had impaired his *Filaria* work. My studies of 1893 on malaria proved the contrary; and then my find of malaria spores in the salivary glands of mosquitos in July, 1898, suggested that *Filaria* embryos might work their way similarly into the mosquito's proboscis. Did not S. P. James prove this hypothesis simultaneously with Manson and Low in 1900? The obituary does not mention these points.

The theory that malaria must have entered Greece about 500 B.C. and helped to cause subsequent decadence there is mine. It was fully stated after my first visit to Greece in a lecture at Oxford (*Journal of Tropical Medicine*, November 15th, 1906), and was almost self-evident from the first. W. H. S. Jones subsequently added valuable historical corroboration in a book dedicated to me; but I do not see

why your biographer gives the credit to Macculloch, who, when he wrote in 1827, could not possibly have been able to adduce sufficient scientific reasons for such views.

Of course Manson did not invent the mosquito theory of malaria. Many strong reasons for it were given long before him, but he added the strongest one of all. It consisted of two parts. The first part, which indicated merely some suctorial insect, was probably the profoundest induction ever made in medicine. But the second part was quite wrong and misled him and me like a will-o'-the-wisp for more than two years. It was entirely my own new method which subsequently gave us the mosquito cycle, the mode of infection, and the species of mosquito; and it was MacCallum's work of 1897 which finally exposed the previous error.

The story of grants promised to Manson by the British Medical Association but refused by the Royal Society is curious. The Society tells me that it can find no record of the application; but he certainly wrote to me on July 10th, 1895, that "the Royal Society have declined to give me the grant I asked for." Yet he does not mention the British Medical Association. What was the date of its grant?

Can anyone say why Manson did not use the opportunities and material (both malaria and mosquitos) which he had in his hospital at the Albert Docks to prove his own theory? They were often much better than mine in India, and I urged him at least twice to do so.

C. Finlay did not discover that *Stegomyia calopus* carries yellow fever; he only conjectured so. Surely there is a wide interval between speculation and proof.

So also—fer obvious statistical reasons—the Campaigna experiment was no "conclusive test" of the mosquito theory of malaria. Yet we see it often trotted out as such in the lay press. It appeared even in the *Times'* obituary notice of Manson—where, by the way, Bruce is claimed as his disciple!

I fear that your biographer's references to my work, though kindly meant, will only confuse matters more; but I am too tired of the subject to attempt to correct them. The facts have been set out often enough, especially in your own pages.—I am, etc.,
RONALD ROSS.

London, April 15th.

*** The minutes of the meeting of the Journal and Finance Committee of the British Medical Association held on January 16th, 1895, recommended "That Dr. P. Manson be granted £150 to assist him to proceed to the West Indies to study the malarial parasite." The minutes of the Council show that the recommendation was accepted by the Council at its meeting on the same day.

The grant was made in consequence of the interest excited by Manson's paper "On the nature and significance of the crescentic and flagellated bodies in malarial blood," published in the *JOURNAL* of December 8th, 1894. In this paper, after describing the changes observed in the parasite in the blood vessels, Manson asked, "What is the provision made for the life outside the body?" He described the changes observed in the parasite in blood withdrawn from the body, laying special stress on the crescentic body. It had, he stated, not been observed to undergo development in the circulating blood; it had been observed to undergo development after it had been removed from the human body, and only then—a circumstance which, with other considerations, he said, "points to the conclusion that the crescentic body is intended to carry on the life of the species outside the human body." He concluded this section of his paper as follows:

"Therefore, seeing that neither the physiological arrangements of the human body, nor pathological processes, nor the inherent powers and organism of the parasite itself provide for its escape from the human body, and seeing that such escape is necessary, some extraneous agency, such as is likely to be frequently, if not constantly, supplied in natural conditions, must come to the assistance of the parasite. What is this extraneous agent which assists the malarial organism to escape from the human body?"

He then said that a similar problem had presented itself to him in connexion with the filaria of the blood—*F. nocturna*; and went on:

"The mosquito having been shown to be the agent by which the filaria is removed from the human blood vessels, this or a similar suctorial insect must be the agent which removes from the human blood vessels those forms of the malaria organism which are destined to continue the existence of this organism outside the body."

In the concluding paragraph of his paper he wrote:

"The hypothesis I have ventured to formulate seems so well grounded that I for one, did circumstances permit, would approach its experimental demonstration with confidence."

There is no information in this office as to whether Manson actually made an application to the Royal Society, but it is known that he intended to do so. He did not carry out his intention of going to the West Indies, so that the grant made to him by the British Medical Association was not claimed.

April 24th, 1922.

VOLUNTARY HOSPITALS.

SIR,—Many letters have appeared recently in both the medical and the lay press as to the payment of medical staffs of "voluntary hospitals." The main point in dispute is the meaning of the term "voluntary hospital." If we accept the ruling of Logic, the connotation of a term consists of the qualities or attributes possessed by objects bearing that name. No amount of sophistry can alter the fact that both the lay public and the medical profession have hitherto regarded medical service, given gratuitously by an honorary medical staff, as an outstanding feature, or attribute, of the voluntary hospital. Yet we are now invited to believe that the conditions of service of the medical staff have no bearing on the voluntary status of a hospital, and the chairman of the Hospitals Committee of the British Medical Association has suggested that the same is true of the services of the board of management. This argument is urged upon us by those who profess themselves strong advocates of the retention of the voluntary hospital system.

It is an undoubted fact that the trusted weapons of the skilled debater are material fallacies, often used without deliberate intent to mislead. In this controversy the time-honoured argumentum ad populum has been freely employed—that is, an argument resting not upon the merits of the case, but upon the stirring up of feelings likely to prevent the formation of a dispassionate judgement. A woful picture has been painted of the dire fate which will overtake us if we fail to claim at least a "peppercorn rent" out of the smallest payments made by patients to the hospitals. It has been argued that patients who pay only a proportion of the cost of their maintenance believe that they are paying for medical treatment as well as for food, and apparently we are urged to give colour to this delusion. Surely this is beside the point! The question is not what the patients *think*, but what we *know*, and we must be well aware that to deprive the hospitals of a part of sums paid for maintenance is to diminish our hopes of avoiding the evils of State control. Moreover, the average hospital patient is not devoid of common sense, and it is incredible that he regards a sum of (say) 2s. per diem as sufficient to cover expense of maintenance and medical fees.

If we accept this policy we can no longer claim the title of "honorary" medical officers to our hospitals without incurring deserved derision from the public. The lay press has not been slow to seize upon it, and it has given the mud-throwing section of the public a plausible excuse for making the profession its target.

Those who are opposed to this policy of the British Medical Association are strongly urged to instruct their representatives to vote for the rider to the Brighton resolution at the Annual Representative Meeting in July next. The purport of this rider has been explained by Mr. Parry in his letter in the BRITISH MEDICAL JOURNAL of April 15th.—We are, etc.,

G. O. LAMBERT.
J. L. JOYCE.

Reading, April 17th.

THE HOSPITAL POLICY OF THE LABOUR PARTY.

SIR,—Any experienced practitioner who has read the programme of the Labour party with regard to medical administration cannot fail to be struck by its resemblance to the advertisement of a patent medicine. The symptoms are graphically described, great stress is laid upon those which are of least significance, and the conclusion is irresistible—that the only remedy which can cure the disease is the advertised nostrum.

Does any impartial observer believe that a tenth part of the Labour party's promises can come to fruition? It is already pledged to such enormous expenditure in other directions that little can be left for medical reform, and what useful purpose is served by a lofty and comprehensive programme which will never be realized?

One of the curious and unexpected results of the late war is the predominance of the doctrinaire. It might be thought that, of all experiences, a war would bring home to humanity the realities of life. The exact reverse has been the case, and there has probably never been a period in which the breach between theories and facts was so wide. A perusal of the literature, medical and sociological, of the last two years

will, I am sure, convince anyone of the truth of this statement. A psychological analysis of the fact would be interesting, but so far I have not seen an adequate explanation of it.—I am, etc.,

A. CAMPBELL STARK.

Wanstead Park, Essex, April 23rd.

REDUCTION OF MEDICAL FEES.

SIR,—Dr. Ellis's letters in the JOURNAL of April 1st and 22nd appear to me to be based on unsound reasoning. Medical fees were increased by 50 per cent. some years after the cost of living had risen well over 100 per cent. During that time the public were financially the gainers. This delay was due to patriotic reasons during a time of national stress and danger. It should not be used as a precedent for reduction of fees when the cost of living still remains over 80 per cent. above the pre-war level. For such a step Dr. Ellis brings forward as reasons "loss of prestige, self-denial, honour"—high-sounding terms, but a bitter mockery to the medical man, who finds it hard to make both ends meet and put away a trifle for his old age, even if his practice returns a figure which, pre-war, would have meant a fair livelihood.

The medical profession is not in honour bound to fall into line with those who, like civil servants, have been compulsorily required to submit to a reduction of their bonus and salaries. By how much were those salaries increased? In the great majority of cases by very much more than 50 per cent. The great majority are still well over 50 per cent. above pre-war level.

Why Dr. Ellis mentions civil servants in particular is not clear, as they are in no way comparable to medical men. Their appointments are pensionable; therefore they are not compelled to save for their old age or for days of sickness. Again, they can live in what style they like; they are not forced to buy or rent houses of good appearance, keep neat maidservants, buy and maintain motor cars, all at prices at least 80 per cent. above the pre-war level. All these must the medical man do, should he wish to earn a living in practice.—I am, etc.,

W. HERBERT BUTCHER.

Leicester, April 24th.

"ALASTRIM."

SIR,—The introduction into medical nomenclature of the word "alastrim" is much to be deplored. It is supposed to signify small-pox of a mild type, but as a matter of fact the true meaning of the word is not known. If we must import new terms—and it is a practice we Britishers seem to revel in—an attempt might at any rate be made to see that they have some utility. Already the use of this silly word is beginning to cause confusion in the lay mind, and as it is quite superfluous I would earnestly appeal for its utter banishment.—I am, etc.,

Leeds, April 23th.

J. JOHNSTONE JERVIS.

REPORTS OF SOCIETIES.

SIR,—At the annual meeting of the Pathological Section of the Royal Society of Medicine a discussion took place with reference to the publication in the medical journals of reports of papers and of the discussions arising out of them.

It was decided to continue the present policy of the Section, which holds that it is undesirable that any reports should be published except such abstracts as the authors of any papers may hand to the secretary, with the request that he shall forward them to a particular journal. It was also decided to continue the present rule that no report of any discussion be published. Under the resolutions passed the secretary will in future, at the request of any author, forward an abstract provided by the latter to any particular medical journal for editorial consideration with a view to publication.

I have been instructed by the Section to bring these resolutions to your notice.—I am, etc.,

W. W. C. TOPLEY.

Honorary Secretary, Institute of Pathology, Charing Cross Hospital Medical School.

London, W.C.2, April 20th.

ANOTHER CONFUSION OF NAMES.

SIR,—The recent correspondence in the Times newspaper concerning the fees of practising consultants has brought a considerable addition to my morning mail. These letters are written apparently under the impression that I am the medical correspondent of that paper. Will you allow me to make it clear that I have not, and never have had, that honour?—I am, etc.,

London, W.1, April 22nd.

C. M. WILSON.

with Collius Warren of the second edition of the *International Textbook of Surgery*. His other writings included the Bradshaw lecture on cancer, papers on amputation of the breast and the operative treatment of varicose veins, and an article on radium and cancer published in these columns in 1914.

The work of medical benevolent societies and other philanthropic agencies made a strong appeal to Pearce Gould. He was for long Chairman of the Society for the Relief of Widows and Orphans of Medical Men, Chairman from its inception of the War Emergency Fund of the Royal Medical Benevolent Fund, member of Council of the Metropolitan Hospital Sunday Fund and the Royal Surgical Aid Society, and Consulting Surgeon to the Royal National Mission to Deep-Sea Fishermen. His devotion to the cause of temperance was well known, and he was often persuaded to address public meetings and contribute articles in favour of total abstinence to temperance journals. Only a week or two before his death he had resigned the Presidency of the Society for the Study of Inebriety.

In August, 1914, he was mobilized as Major R.A.M.C.(T.F.) in charge of the surgical division of the Third London General Hospital, and was promoted lieutenant-colonel in 1915. On several occasions he acted temporarily as commanding officer, and after the armistice he again took charge until the closing of the hospital eighteen months later. During those six years he also served as consulting surgeon to various Red Cross and auxiliary hospitals. In 1917 he was one of a party of surgeons sent to France by the D.G. A.M.S. to report on the Carrel-Dakin treatment of war wounds; and from the institution of medical appeal tribunals he served as a medical member of the officers' board. He was created K.C.V.O. in 1910, and in recognition of his war services C.B.E.(Mil.) in 1919.

He retired from active practice a year ago and went to live at Hampstead. For nearly thirty years he spent his holidays on Dartmoor; his outdoor recreations were walking, gardening, and fishing. A fine tenor voice made him in much request at students' concerts in earlier days, and his interest in music was kept up until the end.

Sir Alfred Pearce Gould married twice, and had three sons and five daughters. His third son was killed in action in France; his second son is assistant surgeon to the Middlesex Hospital. A largely attended memorial service was held on April 24th at the Regent's Park Baptist Chapel, of which he had been a regular member for forty-two years and an elder for the past thirty years. He was one of the outstanding laymen of the Baptist denomination, and gave a large share of his time and thoughts to the missionary movement.

A HOSPITAL COLLEAGUE writes:

Gould was a brilliant clinical teacher, and his classes were always crowded. Being before everything a general surgeon, with practical knowledge of almost every branch of surgery, he could teach profitably on whatever material came to hand. There were no bare patches. His commanding presence, intense earnestness, and admirable exposition compelled attention. It is not surprising that he attracted pupils, not only from the whole of the United Kingdom, but also from the overseas dominions and elsewhere. He never allowed his extensive private practice to interfere with his hospital work. He was always very punctual and never failed to find, on arriving at the hospital, a large gathering of students and others waiting to accompany him on his rounds. The tramp of Gould and his class was a familiar sound in the hospital in those days. He took a very keen interest in the welfare of the students, and was the member of the staff usually appealed to by them in times of trouble or difficulty; and many were the occasions on which he lent a helping hand. They found in him a staunch friend and wise counsellor.

Gould was a strong, self-reliant man, holding convictions which were very difficult to shake. He was impatient of criticism and at times rather quick-tempered. In debate he was rather too apt to undervalue the other point of view, but in spite of these defects of his qualities he was a most valuable member of committees. He was an indefatigable worker and never spared himself. He took life very seriously and rarely unbent, except in his own beloved home circle, where he was a charming host and delighted to welcome his friends. His quiet, assured manner, wide knowledge, and well-balanced judgement made him a first-rate consultant. I have seen patients a little afraid of him at first, but only until they had discovered, which they soon did, that beneath his somewhat stern and rugged exterior there lay a warm heart and kindly

disposition. Gould truly devoted his life to his hospital and profession. He was a fine upright man, a most loyal and generous colleague, and a faithful friend.

Another colleague sends the following appreciation:

Those who were closely associated with Sir Alfred Pearce Gould professionally must always have been impressed by two strong characteristics—his zeal for his profession and his remarkable devotion to the best interests of his patients, why trusted him implicitly and always seemed to know that his energies and great surgical talents were being employed to the utmost on their behalf. He was a general surgeon in the best sense of the term, for although he was always ready to recognize superior skill in those who devoted themselves to special branches, he was always insistent that a sound general training should form the foundation of a specialty. It was probably by his forcible teaching that he will be best remembered, and those who had the privilege of being taught by him in the wards will call to mind the way in which he insisted that the students should examine patients for themselves and verify what had been told them. What struck us particularly in the wards was the thoroughness of his examination of the patients and the amount of thought he would expend before making a diagnosis, and the correctness of the latter when he had made up his mind. "Lightning diagnosis" had evidently no charm for him.

As an operator he was clean, thorough, and extremely careful, preferring large surgery to that which is smaller and finer; never in a hurry when actually operating, and particular about the closing of wounds and dressings. In removal of the breast for malignant disease in particular he was a great advocate of a thorough and complete operation. To the surgical treatment of malignant diseases he devoted a great deal of attention, advocating extensive removal as the best method of extirpation; and yet one remembers his stating that, in his opinion, the last word in the cure of malignant disease was probably not to be the surgeon's knife. His enthusiasm for treatment by radium when this was first introduced was well known, and if he was somewhat disappointed in the results he did not cease to believe it was a step onwards in a direction in which he was so much interested. A very busy practical life left Sir Alfred but little time for writing, so that his published works have been fewer than we could have wished; he himself would probably have said that the *Elements of Surgical Diagnosis* was his best work, for it was a subject in which he was not only interested but was undoubtedly a great authority. In assisting him in the preparation of his Lettsomian lectures on diseases of the blood vessels at the Medical Society of London, which were the outcome of a large amount of work, revision, and study, one was particularly struck by his determination that what he did should be done well; he was joint editor of the *International Textbook of Surgery*, and to this work he devoted a considerable amount of time and energy. If his other contributions to medical literature in the form of lectures and communications to journals have not been many, they have borne the impress of a wide knowledge and experience.

ROBERT SHINGLETON SMITH, M.D., F.R.C.P.,

Consulting Physician, Bristol Royal Infirmary.

We regret to record the death of one of the leading physicians of Bristol, Dr. R. Shingleton Smith, which took place on April 15th at his residence, Deepholm, Clifton Park, at the age of 76.

Robert Shingleton Smith was born at Sherborne, Dorset, in 1845, went to school at Queen's College, Taunton, and received his medical education at King's College Hospital, London. He was senior scholar, associate, and honorary fellow of King's College, and university scholar in midwifery. He graduated B.Sc. in 1866, M.B. in 1867, and M.D. (gold medal) in 1868. He took the diplomas of M.R.C.S. Eng. in 1867 and M.R.C.P. Lond. in 1877, and was elected F.R.C.P. in 1885. The honorary M.D. degree of the University of Bristol was conferred on him in 1912. After holding office as Sambrooke medical registrar at King's College Hospital, and resident medical officer at the St. Pancras and Northern Dispensary, he went to Bristol as house-surgeon at the Royal Infirmary. He was appointed honorary physician to Bristol Royal Infirmary in 1873, and continued to hold that appointment until 1905, when he was elected consulting physician. He also became consulting physician to the Bristol Dispensary and to the Cosham Memorial Hospital, and he was president of the Winsley Sanatorium, Bath.

Dr. Shingleton Smith did valuable work in connexion with the foundation of University College, Bristol, which has since obtained incorporation as a university, particularly during the time he was honorary secretary to the organizing committee of the college. Subsequently he became the lecturer on physiology at the University College, and later professor of medicine. He was held in high esteem by his medical colleagues, and was one of the founders of the Bristol Medico-Chirurgical Society, of which he was honorary secretary for fourteen years, and subsequently president. He was an old member of the British Medical Association, and a former president of the Bath and Bristol Branch. For twenty years he was the editor of the *Bristol Medico-Chirurgical Journal*, which prospered greatly under his guidance, and he was the author of numerous contributions to medical literature, particularly on the subject of tuberculosis.

Dr. Shingleton Smith had many interests outside medicine, especially in astronomy, archaeology, and horticulture. His wife died some years ago; the youngest of his three sons was killed in Mesopotamia during the war; more recently his second son, Dr. Lionel Shingleton Smith, died as the result of an accident while in practice; and much sympathy is felt with his surviving son, his three grandchildren, and with his sister, who lived with him.

A friend and colleague writes: Brilliant as a student and attaining the highest eminence as a consulting physician, it is rather the warm-hearted, generous, kindly man, always so ready to help others, to encourage his younger colleagues, to relieve those in trouble, that those who were privileged to know him and to come under his influence now mourn. Simplicity in mind and manner and a gentle courtesy made one almost forget his scientific eminence and feel only the presence of a friend. Yet how hardly his courage was tried when, after prolonged illness, he lost both his beautiful daughters, two of his sons, and also his wife, only his intimate friends were allowed to realize. I was one of his class of students in physiology, and later his house-physician, till I became his colleague on the Royal Infirmary staff for seventeen years, until he retired. For many years he entrusted his private practice to my care whenever he was away from home, but it was the intimate friendship in his family that was the greater privilege. One realized that his relaxations were activities, that the hours snatched from his very full and busy professional life were devoted to his garden and hothouses, to reading the best of current literature, or visits to the Zoological Gardens, in which he took a most active interest, or in the evening observing stars and planets with his big telescope. Otherwise he was examining histological slides, unless he was entertaining his friends hospitably with his family. His energy, up to the last few years, seemed inexhaustible; and though his interests were manifold, the work he put in was never perfunctory. It seemed difficult to realize that shortly after he had started in practice he developed pulmonary tuberculosis, and was sent on a voyage for his health. With a keen sense of humour, he was a fine raconteur, and, among many stories of his life, one recalls his amusement at his having won a gold medal in Obstetrics when he had read for honours in Medicine and took but little interest in Obstetrics, whereas his fellow student who read for honours in Obstetrics snatched the gold medal in Medicine, although his interest was devoted to Obstetrics. P. W. W.

THE LATE SIR PATRICK MANSON.

Dr. Charles F. Hamford writes: Sir Patrick Manson has left behind a great inspiration to all who had the good fortune to be closely associated with him, and I would like to add some reminiscences to those which have already been contributed by others.

A lecture on the malarial parasite given by Manson at the Hunterian Society, being the Hunterian oration for 1894, was my first introduction both to the lecturer and to the subject of the lecture. It made a great impression upon me, as I had recently been invalided home from Africa with blackwater fever. When Livingstone College was founded, of which I was the first principal, Manson was one of our earliest lecturers, and in the Livingstone College Report for 1894-95 I find the following note: "Dr. Manson, who during the past year has been appointed lecturer on tropical diseases at St. George's and Charing Cross Hospitals (the only lectureships on this subject connected with the London Medical Schools), gave instruction on some diseases of the tropics." Thus it came about that before there was any School of Tropical

Medicine Manson in his usual generous way thought it worth while to help young missionaries to the tropics to obtain some elementary knowledge of the risks incidental to those parts of the world. Nor did he only lecture to these students, but took them round his wards at Connaught Road, and this he did for many years, often working far beyond his strength. On one occasion I remember him coming to his lecture in a cab accompanied by his daughter in order that she might help him in and out of the college. From those days I constantly consulted him on matters relating to the spread of knowledge of tropical diseases to the general public, and he was always sympathetic and recognized the great importance of this work.

Another reminiscence relates to his address to the Royal Colonial Institute, in which he announced the experiments which it was proposed to carry out in the Roman Campaign, Drs. Low and Sambon being in charge of the expedition, as described in the obituary notice in the *BRITISH MEDICAL JOURNAL*. I have often heard research workers describing their successful experiments, but I have never heard any medical man announce beforehand to a public audience that he intended to make a certain experiment, giving the details, and stating that it would be successful. To his great credit and to the credit of those who did the work, and also those who allowed themselves to be the subjects for inoculation with infected mosquitos, the experiment was brilliantly successful.

In conclusion, let me give two instances, among many, of Manson's powers of diagnosis.

An Indian missionary who had suffered from a prolonged attack of chronic fever on his return from Bengal was seen by Manson. He had been treated by one doctor for enteric fever and by a second for malaria with large and continued doses of quinine. Referring to this latter Manson made the characteristic remark, "Why cannot people take 'No' for an answer?" He regarded the reaction to quinine as a matter of great diagnostic value. Eventually he identified this patient as a case of kala-azar, treated him successfully with atoxyl, with the result that he recovered, and some years later returned to India.

Another instance was that of a missionary lady who went to him with unusual attacks of fever. He found trypanosomes in her blood, which had only previously been found in the human blood in Forde's case in the Gambia, which was seen by Dutton. It was, I think, while this patient was under treatment for trypanosoma fever that Castellani found trypanosomes in cases of sleeping sickness in Uganda. Manson's patient died of sleeping sickness, a remarkable confirmation of the importance of this discovery.

How much we all owe to this great man it is difficult to estimate. He has left us an example of painstaking research, indomitable perseverance, and kind consideration; his monument is in our hearts.

Dr. PHILIP MANSON-BAHR writes: Few teachers of medicine of modern times can have exercised a more profound or stimulating influence upon their colleagues or pupils than did the late Sir Patrick Manson. He was so eminently human in all his thoughts, words, and actions that he attracted all those with whom he came into contact. His attitude of mind, always a lofty one, was never better exemplified than when handling a knotty scientific problem: What better advice could be extended to any young man entering the field of research than the following lines he wrote to me in Fiji in 1910:

"Never refuse to see what you do not want to see, or which might go against your most cherished hypotheses, or against the views of authorities. These are just the clues to follow up, as it also, and emphatically so, the thing you have never seen or heard of before.

"The thing you cannot get a pigeon-hole for is the finger-point showing the way to discovery."

Manson's influence naturally extended far beyond the confines of the school he founded; the moral effect of his work was worldwide. One instinctively knew that his hypotheses, founded as they always were upon intensive contemplation, had an uncanny habit of coming true. In this respect may be cited his forecast of the probable life-history of *Filaria loa* and of the *Schistosoma haematobium*. He readily gave of his store of knowledge to all who sought after it, and there are many who mourn his loss and readily acknowledge the debt they owe him. His interest in the progress of tropical medicine and his absorbing passion for that child of his creation—the London School of Tropical Medicine—remained unabated to the end. He was actively engaged in searching for fresh fields of scientific exploration and in furthering the interests of the Tropical School till he became unconscious. Those who were so fortunate as to have been associated with him feel most strongly, great as

was his influence during life, that it will be greater still now that he has gone, and that the world cannot yet adequately apport on the exact place the name of Manson will fill in the history of medicine; but that that place will be a very eminent one there can be no doubt whatever.

H. W. KAYE, M.D.

Director of Medical Services, Ministry of Pensions.

THE untimely death of Dr. H. W. Kaye, of the Ministry of Pensions Medical Department, at his home at Hatfield Perere, on April 21st, is a loss not only to his wide circle of friends but to the Department and to the country. In the Ministry of National Service, and still more in the Ministry of Pensions, where, as Director of Medical Services, he was in charge of the department providing treatment to war-disabled officers and men, he found congenial spheres for the employment of his great and special abilities and experience, and also for the actual expression of the fundamental motive of his life—the betterment of the health of his fellow beings. If ever a man consecrated and shaped his life to this noble end and died in doing so, it was Kaye.

Henry Wynyard Kaye was educated at Winchester, Oxford, and the London Hospital; he graduated B.A. at Oxford in 1898, M.B., B.Ch. in 1903, and M.D. in 1908. He passed several years in practice at Rome, San Remo, and Strathpeffer; he was so employed when war broke out. He served in France continuously from 1914 to 1918, when he joined the Headquarters Staff of the Ministry of National Service under Sir James Galloway, Chief Commissioner of Medical Services, to whom he was attached as personal assistant. When the recruiting activities of that Ministry ceased and its medical organization became amalgamated with the Medical Department of the Ministry of Pensions early in 1919, Dr. Kaye became a Director of Medical Services under the Director-General, Colonel Sir Lisle Webb, K.B.E., C.B., C.M.G. At that time Dr. Kaye was in charge of the Medical Services of the "Red Cross" work.

He was in charge of the Department of Medical Statistics and General Medical Information. He was placed in charge of the provision of treatment by the Ministry, continuing, however, the collation of medical statistics until this work passed to the Statistical Department of the Ministry.

Kaye's life was one of incessant activity. In addition to his official duties, he acted as Secretary of the Medical Disability Committee, consisting of representatives of the Royal Colleges in London and a small number of Ministerial officials, which advises the Minister of Pensions on medical questions and has been of inestimable service. He was also a member of the Comité Permanent Interallié and sat on the Editorial Committee of the *Revue Interalliée pour l'étude des questions intéressant les Mutilés de la Guerre*, the official organ of the Comité. Last year he attended the General Congress of the Committee at Rome as the principal delegate of the Ministry and received from the King of Italy the Commandership of the Order of the Crown of Italy. To these and to other committees on which he sat—for instance, the War Office Shell-shock Committee—he brought a clear and critical but always constructive mind, a ready wit, a friendly presence, and a courtesy and patience which never varied.

Stricken down by pneumonia whilst addressing a meeting of his medical colleagues at Leeds, he fell, as he would wish, at the post of duty. An indefatigable worker, a most loyal servant of the public, a delightful comrade, and a true friend, his death leaves a gap which no doubt may in time be filled—except in the hearts of those who knew and loved him.

THE LATE MR. ARTHUR BACOT, F.E.S.—The funeral of the late Mr. Arthur Bacot, entomologist to the Lister Institute of Preventive Medicine, which took place in the British Cemetery, Old Cairo, on April 12th, was attended by a large number of representatives of the different branches of scientific work in Cairo. The coffin was carried to the grave by his friends and colleagues from the Laboratories, both Egyptian and British, and a mark of appreciation of his work was the large number of Egyptian doctors and scientists present. Among the many senders of wreaths and flowers were the staff of the Lister Institute, London, the staff of the Public Health Laboratories, Cairo, the Director-General of the Egyptian Public Health Department, the staff of the Fever Hospital, Abbassia, in addition to many personal friends.

We much regret to announce the death of Dr. JOHN ADAMS, one of the best-known general practitioners of Glasgow, a former chairman of the Scottish Committee of the British Medical Association and member of Council. We hope to publish a memoir in an early issue.

Medical News.

DR. THOMAS FAWCITT, who retired from active practice in Oldham in 1920 after fifty years of medical and philanthropic work in the town, has been admitted to the honorary freedom of the borough. On the casket in which the roll was presented there was a view in enamel of the Oldham Royal Infirmary, of which Dr. Fawcitt was the first medical man to be elected president. After the freedom was conferred the Testimonial Committee presented to Dr. Fawcitt his portrait in oils. This portrait has been given to the corporation and by them added to the permanent collection in the art gallery.

DR. DAVID HUSKIE, provost of Moffat and an ex-president of the Border Counties Branch of the British Medical Association, has been presented by his friends with a Fiat motor car in recognition of his services to the town and district during the last quarter of a century in his professional capacity and also as civic head of the burgh. Mrs. Huskie was on the same occasion presented with a set of furs and muff.

AT the meeting of the Senate of the National University of Ireland, on April 21st, Dr. Maurice R. J. Hayes, F.R.C.S.I., was appointed to the Professorship of Materia Medica and Therapeutics, University College, Dublin.

THE National Council for Combating Venereal Diseases has, at the request of the Corporation of London, called a conference in the Council Chamber, Guildhall, on Wednesday, May 3rd, at 10.30 a.m., to consider "how persons infected with venereal disease can best be retained under treatment until a non-infective condition has been attained." The proceedings will be opened by the Lord Mayor, and Lord Gorell (President) will take the chair.

THE annual meeting of the Medical Missionary Auxiliary of the Church Missionary Society will be held in the Queen's Hall, Langham Place, W.1, on Wednesday, May 3rd. The chair will be taken by Sir Leonard Rogers at 7.30 p.m., and among the speakers will be Dr. R. B. Coleman (Old Cairo), Dr. D. D. Main (Hangelow), and Dr. Emmeline M. Stewart (Isfahan, Persia). Tickets for admission can be obtained on application to the Loan Department, Church Missionary Society, Salisbury Square, Fleet Street, E.C.4.

AS already announced, a lecture on the human neocerebellum will be given by Professor Winkler on Wednesday, May 3rd, at 1, Wimpole Street, W. The chair will be taken by Sir Frederick Mott; admission is free without ticket.

A COURSE of four lectures on "Insects and disease" will be given at University College, London, by Sir Arthur Shipley, G.B.E., F.R.S., on Tuesdays, May 2nd, 9th, 16th, and 23rd, at 5 p.m.

A COURSE of eight lectures on pathological research in its relation to medicine will be given during the summer session in the Lecture Room of the Bacteriological Department of the Institute of Pathology and Research, St. Mary's Hospital, Paddington, W. The lectures, which are open without fee to members of the medical profession and all students of medical schools, will be delivered on Thursdays, at 5 p.m. The first of the series was given by Sir Almonroth Wright on Thursday last, when the subject was "New avenues in immunization." Sir Archibald Garrod, Regius Professor of Medicine in the University of Oxford, will deliver the lecture, on May 4th, on "More inborn errors of metabolism."

DR. C. B. GERVIS, formerly vice-chairman, has been appointed chairman of the Seaford Urban District Council for the ensuing year.

PERMISSION has been granted to Dr. R. Hensleigh Walter, late medical officer of the Norton Manor Auxiliary Hospital, Somerset, to wear the insignia of the Médaille du roi Albert conferred on him by the King of the Belgians for war services.

WITH reference to the statements recently made that a method had been discovered of disinfecting wool or other material infected with anthrax by means of ultra-violet rays, it is reported by the Home Office Committee on Anthrax that a test of the method was recently carried out by the Committee at Liverpool, in which the apparatus was supplied and manipulated by the inventors, and that samples taken from bales of wool subjected to the process showed, on being examined bacteriologically, that the anthrax spores had not been destroyed and that there was no indication of disinfection.

ON the occasion of his retirement, after thirty-seven years' service as medical officer of the Romford Poor Law Institution, Dr. J. A. Fraser was entertained by the officers and staff of the institution and presented with an illuminated address, a kit-bag, a travelling companion, and a clock.

THE University of London Press, Ltd., announce the very early publication of a popular volume on *Suggestion and Mental Philosophy*, by Dr. William Brown, Wilde Reader in Mental Philosophy in the University of Oxford. The book is intended as an elementary summary of modern methods on mind cure, and comprises an appreciation and criticism of M. Coué's views, indicating their relation to other methods of suggestion and doctrines of psycho-analysis.

L'ART ANCIEN S.A., of Lugano, Switzerland, has published, in English, a catalogue of early medical books. This catalogue furnishes a description of 16 medical manuscripts of the Middle Ages, 26 medical books printed before the end of the fifteenth century, and more than 175 books of the seventeenth and eighteenth centuries.

INCREASES in the tuition fees in the medical department for the next academic year have been announced by the Johns Hopkins University; from next October the cost of tuition at the medical school will be 300 dollars a year instead of 250 dollars.

A COMMITTEE has been organized in Spain to hold a national demonstration on the occasion of the retirement of Dr. Ramon y Cajal from the medical school of Madrid, which is to take place on May 1st. The president of the organizing committee is Dr. C. M. Cortezo, president of the Royal Academy of Medicine in Spain, and the plans of the committee include a special edition of Cajal's works and the erection of a monument.

IN the week ending April 22nd the number of deaths from influenza in the 105 great towns of England and Wales was 93, as compared with 109 in the previous week.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Attology, Westrand, London*; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

B. COLI BACILLURIA.

"IGNORAMUS" asks the following questions:

1. In an otherwise healthy subject what significance is to be attached to the presence of the *Bacillus coli* in the urine when no cystitis is present?
2. How does the bacillus get into the urinary tract?
3. Is the operation of internal urethrotomy justified when the bacillus can be demonstrated in the urine?
4. What treatment is best calculated to banish the bacillus from the urine and to prevent its recurrence?
5. Is prolonged medication with sublimed sulphur harmful to either the kidneys or prostate?

* * * The following brief answers may be suggested to these questions:

1. A bacilluria may indicate a lesion anywhere in the urinary tract, or in certain cases occurs without any such lesion existing, the kidneys acting merely as a means of eliminating bacilli in the blood stream. The absence of any symptoms of cystitis is less important than the absence of pus cells.
2. Bacilli are carried into the blood stream and passed through the kidney. This is the commonest mode of infection. Direct infection of the bladder from the bowel also takes place, but this is probably a less common method.
3. Yes.
4. Treatment of any bowel condition such as constipation is of prime importance. The diet should contain very little milk, and an excess of fluids. Urotropin is sometimes of use.
5. No.

INCOME TAX.

"J. R. T." inquires as to the deduction due in respect of his "first automobile."

* * * (a) All running costs except those incurred in connexion with private as distinct from professional use, and (b) the cost of any cycle or other means of conveyance sold on the purchase of the car, less the sum received for its sale.

A deduction for fall in value of the car cannot be admitted by the Revenue authorities, as that form of allowance is restricted to traders as distinct from professional men. The replacement expenditure is allowed in lieu of the annual deduction for depreciation.

LETTERS, NOTES, ETC.

TOUTING MONEY LENDERS.

WE are invited once more to warn members of the medical profession, especially the younger members, against falling into the hands of money lenders; once in, it is often very difficult to get out. The circulars issued are often insidiously expressed in the hope of appealing to the special circumstances of the recipient. We have recently been shown a circular letter of a London money lender offering exceptionally low terms for private cash advances to medical practitioners, repayable quarterly out of panel or other funds. Although it is stated that "unpleasant money-lending methods will be completely eliminated," we should not be disposed to place much reliance on this promise.

THE CINEMATOGRAPH AND VIVISECTION.

THE DUCHESS OF HAMILTON, in the course of a letter on the subject, writes: My attention has been drawn to an article in the BRITISH MEDICAL JOURNAL of April 8th, in which you refer to my letter to the *Times* on the subject of the cinematograph and vivisection before students. You say that it is not true that painful experiments are unnecessarily performed to illustrate lectures to medical students.

May I say in justification of my letter which you quote that the Act in no way guarantees absence of pain during experiments before students. The law does not enforce the presence of an inspector during these experiments, or of a qualified anaesthetist; does not forbid the use of curare or morphine; provides no punishment for those who for purposes of science use light anaesthesia. British physiological textbooks, written for the use of students, contain frequent warnings against deep anaesthesia on the ground that such a condition of the animal frustrates the object of the experiment. The choice of what is "necessary" depends on the individual taste of the vivisector concerned, and records of experiments performed before students show wide divergence of selection. The Act also ignores the obligation of the investigator to give the *coup de grâce* without delay.

THE HEMPEYMA.

THE following story in the current number of the *London Hospital Gazette* is new to us and may amuse a wider audience:

"I was going round the wards the other morning, when I saw one of the most conscientious girl students. 'What have you got there?' I asked in a friendly manner. 'I don't quite know,' she answered hesitantly. '... it's a hempeyema!' 'A what?' I gasped, horrified beyond description. 'A hempeyema!' she replied firmly and unblushingly. 'Why do you call it a hempeyema, and not an empyema?' I asked at last ventily, greatly ashamed, and fearing to hurt her feelings. 'I always did call it an empyema till yesterday,' she explained, 'but ... What happened yesterday?' I interrupted, scarcely able to control my excitement. 'Yesterday afternoon,' she replied, 'the Chief came round and he told us that the first thing to do, with an empyema was to aspirate it!'"

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 32, 33, 34, and 35 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31.

THE appointment of certifying factory surgeon at Neilston (Renfrew) is vacant.

THE appointment of Medical Referee under the Workmen's Compensation Act, 1906, for the Abingdon, Faringdon, Reading, Wallingford, Wantage, Banbury, Oxford, Thame, and Witney County Courts in Circuit No. 36 is vacant. Applications to the Private Secretary, Home Office, by May 13th.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page...	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 427, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

402. Artificial Pneumothorax.

MARAS (South African Med. Record, January 28th, 1922) discusses the indications, scope, and results of therapeutic artificial pneumothorax from an experience of 38 cases during the past eight years. The ideal cases for treatment are those beyond the early stages in which the disease is confined to one lung, free from pleural adhesions, and therefore completely compressible. The usual method of treatment may be given a trial in early cases, but artificial pneumothorax should be considered when signs of ulcerative processes occur in the lung. In an otherwise uncontrolled toxæmia largely due to active processes in one lung, without evidence of active disease in the other, compression of the diseased organ yields quite dramatic results, the pyrexia disappearing, expectoration rapidly diminishing, and the appetite and general appearance improving. In severe or recurrent hæmoptysis the production of artificial pneumothorax acts rapidly, severe hæmorrhage having been checked instantly with permanently good results in at least three cases. Apyrexial cases, without chronic cavities and doing fairly well, should not be so treated unless a toxæmic recrudescence sets in: and the operation is contraindicated when cyanosis, dyspnoea, or long-standing emphysema and asthma complicate the tuberculosis. When lung collapse is prevented by one or two adhesions, section of them is possible, and when a whole lobe or two lobes are adherent a partial pneumothorax may be supplemented by rib section, but the presence of total adhesions necessitates a thorough thoraco-plastic operation. Nitrogen is preferable to atmospheric air as minimizing the risk of infection through imperfect sterilization.

403. Streptococcal Sore Throat.

THJØTTA (Norsk Tidsskrift for Militær Medicin, vol. 26, 1922) describes an epidemic of angina faucium in a Norwegian military camp, to which he was called as an epidemiological consultant. On July 27th he was informed that 50 to 60 men had suddenly developed a sore throat with fever, dysphagia, pain in the back, and aching in every limb. On examination he found diffuse and intense redness of the tonsils and the whole of the soft palate. The tissues were oedematous, and on the tonsils there was a pasty deposit which, in some cases, covered them entirely and in others was limited to the tonsillar crypts and their immediate surroundings. In some cases there was slight enlargement of the glands. Swabs from the throats of 22 cases yielded streptococci in almost pure culture. They were hæmolytic on rabbit blood agar (5 per cent. blood) and were not pathogenic to mice in doses below 0.1 c.c.m. Suspecting that the source of the epidemic was contaminated milk, the author insisted on all the milk supplied to the camp being boiled. The result was a rapid decline in the number of new cases. On July 27th, when the milk was first boiled, the number of new cases was 51. Next day there were only 15, and on the following day only 12 new cases. During the next four days there were only 8 new cases, and these were probably the result of contact infection. None of the cases terminated fatally, and the illness lasted only a few days. Owing to circumstances over which he had no control the author was unable to trace the infection to its source, which may well have been an ulcerating cow's udder, nor was he able to ascertain how many, if any, of the patients remained carriers of hæmolytic streptococci.

404. Sequelæ of Encephalitis Lethargica.

GIRARDI (Il Morgagni, February 28th, 1922) points out the necessity of giving a reserved prognosis in lethargic encephalitis. Many cases, dismissed from hospital as cured, relapse after a brief period of good health—for example, out of 13 cases discharged as cured in 1919-20, 8 returned in 1921 with a recurrence of symptoms. Very commonly the symptoms are like paralysis agitans (dull monotonous voice, rigidity, expressionless face, tremor, etc.), and the more striking, as the patients are usually much younger than the age at which one sees true paralysis agitans. The muscles are easily tired and general asthenia is one of the commonest symptoms—inability to stick at their work, soon tired. Arranging the relative frequency of the sequelæ in a graphic form, it is shown that in order of frequency nystagmus heads the list, followed by pseudo-paralysis agitans, myoclonus, disturbances of sleep (in children often taking the form of semi-delirium), ptosis, facial asymmetry, recurrence of initial

symptoms, diplopia, choriform movements, and lastly, disturbances of respiration. The cerebro-spinal fluid showed no pathological changes. As contrasted with the tremor of true paralysis agitans, the tremor in pseudo-paralysis agitans is increased in movements and is not rhythmic. True paralysis agitans has been known to follow encephalitis.

405. High Blood Pressure with Tachycardia.

MANNABERG (Wien. klin. Woch., February 16th, 1922), on observation of 241 cases of high blood pressure, found that 131, or 55 per cent., had a normal pulse frequency, 103, or 43 per cent., had tachycardia, and 7, or 3 per cent., bradycardia. Only a systolic reading of 180 mm. Hg and upwards was regarded as high blood pressure, and a pulse frequency of 60 and below as bradycardia. Of the 103 cases of tachycardia 38 had a pulse below 50 and 17 above 120, the highest being 140, with a blood pressure of 240 mm. Of the 241 cases 100, or 41 per cent., were men, and 141, or 59 per cent., women; 32 per cent. of the men and 70 per cent. of the women had tachycardia. Mannaberg attributes the tachycardia in these cases to disturbance of the endocrine glands, especially the thyroid. In favour of this view are the predominance of tachycardia in the female sex, the inefficacy of digitalis, the frequent occurrence of sweating, the relative frequency of glycosuria, and the occasional presence of goitre. Treatment is not of much avail, the tachycardia not being affected by digitalis, theobromin, or quinine. Rest in bed is the best means of obtaining temporary relief. High blood pressure with bradycardia is a rare occurrence. In Mannaberg's seven cases, five of which were in men and two in women, the pulse did not fall below 52, and the blood pressure ranged between 190 and 260 mm. Apart from two, aged 55, all the patients were over 60 years of age.

406. Unusual Exanthem Resembling Measles in Infants.

GREENTHAL (Amer. Journ. Dis. of Children, January, 1922) describes an unusual exanthem occurring in infants, preceded by high fever lasting three or four days. Eight cases were observed, the onset being sudden, with temperature ranging from 102° to 105° F., irritability, and refusal of food. Physical signs were absent, no cause for the temperature being discoverable before the appearance of the eruption. After three or four days the temperature fell suddenly coincidentally with the appearance of the eruption, which was chiefly macular, with some papules, and having the appearance of measles, but without any crescentic arrangement, and there were no Koplik's spots. The complaint did not seem to be contagious, only one member of each family being attacked. A leucopenia and a lymphocytosis of over 80 per cent. were important diagnostic signs during the pre-eruptive period. Measles is excluded by the absence of Koplik's spots, and by the fact that as soon as the eruption appears the temperature suddenly drops, leaving the patient apparently perfectly well. The eruption lasts for two or three days, being more pronounced on the neck and trunk than on the face and extremities, and it disappears spontaneously with very slight desquamation.

407. X-ray Treatment in Exophthalmic Goitre.

HAUDER and KRISER (Klinische Wochenschrift, February 4th, 1922) consider the results of x-ray treatment in exophthalmic goitre, basing their remarks on the records in literature and on their own experience in 33 cases, of which 12 only were followed later. Four of these 12 were cured, 7 much improved, 1 slightly improved. The results of various observers are given, and the authors consider that the good effects of the treatment can no longer be questioned. The nervous symptoms are beneficially influenced first and most markedly. The tachycardia diminishes rapidly and the weight increases. The recovery as regards the goitre and exophthalmos occurs relatively slowly; it is often incomplete, and does not occur in all cases. The results are best in young patients and in cases of short duration, but in chronic cases very considerable improvement may be obtained not infrequently. Statistics from literature show that the percentages of unsatisfactory results in operative and in x-ray treatment are similar; but as regards mortality after treatment, the statistics are definitely in favour of x-ray treatment, since death from x-ray treatment does not occur, or at least is quite exceptional. Adhesions of the thyroid capsule are now no longer feared; they are neither constant nor important. The risk of producing increased thyroid activity or of myxœdema is avoidable by caution as to the intensity and mode of application of

the treatment. The effects of x-ray treatment are especially marked in the "formes frustes." The authors conclude by quoting the opinion of Nagelschmid—that no case of exophthalmic goitre should be operated upon without first having had x-ray treatment, and that the mortality of operation is diminished substantially by previous x-ray treatment.

408. The Doctor as Carrier of Poliomyelitis.

WALLGREN (*Upsala Läkareförenings Förhandlingar*, March 15th, 1922) reviews recent advances in the epidemiology of acute anterior poliomyelitis which suggest that, as only one member of a family contracts the disease in most instances, the degree of susceptibility varies enormously in different persons. Another modern view is that propagation of the disease is largely dependent on carriers, and in this connexion the author refers to a personal experience. In the summer and autumn of 1919 he was working in a fever hospital in which there were some poliomyelitis cases. On September 3rd he left this hospital and took up duties in a chest hospital where there was a child, aged 18 months, suffering from tuberculosis of the skin and lungs. The temperature had fallen practically to normal when, on September 20th, it suddenly rose to 39° C. Acute flaccid paralysis of the lower limbs was found; lumbar puncture showed increased pressure, and there was a slight increase in the number of cells. The further course of the case was also characteristic of acute anterior poliomyelitis, and by a process of elimination the author comes to the conclusion that he was the carrier responsible for this case, and he is inclined to suspect that this sinister rôle is not infrequently played by doctors.

409. Lupus Treated with General Carbon Arc Light Baths.

HEIBERG and CARLWITZ (*Brit. Journ. of Derm. and Syph.*, March, 1922) have treated a number of cases of lupus with general carbon arc light baths as the only form of therapy, and have proved that this alone can cure lupus, although the cure is hastened by the simultaneous local application of Fiussen light. The light baths were given for two and a half hours' duration three times a week, and in the cases reported improvement was generally perceptible after twenty baths, and after about sixty baths there was no sign of the disease in the most successful cases. The paper is well illustrated with photographs showing the macroscopical and microscopical appearances of lesions before and after treatment. Microscopically it is found that in the small lesions the nucleus and protoplasm of the epithelioid cells gradually lose the power of staining, are disintegrated and absorbed. In larger lesions the same absorption takes place, and at the same time there is an active proliferation of connective tissue. Finally, all that is left is young connective tissue rich in cells, which differs from its surroundings on account of the absence of elastic tissue. But the dissolution and absorption of the epithelioid cells is the essential consequence of treatment; the subsequent connective tissue changes are of secondary importance.

SURGERY.

410. Operations for Carcinoma of the Rectum.

DEVINE (*Med. Journ. of Australia*, February 4th, 1922) describes two classes of rectal carcinoma. (1) The subjects were young for carcinoma, often between 25 and 40 years of age. Tumour formation and bleeding were marked features—metastases occurred early in glands and liver. (2) Subjects between 50 and 60 years of age with a long history of carcinoma; cicatrization and obstruction were common and metastases rare. The growths remained local and were not of a very malignant type. The situation of the growth may be at the recto-sigmoid junction, mid-rectal, or lower rectal. The two last were approached first from the perineum, the recto-sigmoid from the abdomen first and finished by the perineal route. Operation on women was easier and safer than on men. Patients after 60 years of age do not stand such a severe operation well. The involvement of bladder and prostate was the commonest cause of inoperability. When the growth is low down the operation starts with removal of the coecum and investigation of the growth as to the chance of removal. This operation is easier in women, and a continent anus may be left. The rectum is mobilized, the peritoneum opened on each side, and the sigmoid and its mesentery brought down. The bowel is left outside to slough off, whilst the sphincter and levator ani are sutured over the bowel. There is less shock in this operation, and a continent anus may be obtained in suitable cases. In growth at the recto-sigmoid junction a modified method of Miles's operation was adopted. The sigmoid and its vessels are divided from the abdominal route and the posterior rectal plane stripped to the coecum. The abdominal wound is then temporarily closed and the bowel removed as in the perineal operation.

The peritoneum is then closed from above and the anus implanted as described by Miles. His results have been better by the perineal operation, and they have been mostly in women. Probably in men the modified Miles operation is best. It is a question whether, in view of the limited prospects of function and length of life, the operation should be attempted. In addition to the operation radium tubes are buried and the Coolidge x-ray tube used afterwards.

411. Sliding Hernia.

ACCORDING to DEMEL (*Deut. Zeit. f. Chir.*, January, 1922) sliding hernia is a fairly uncommon variety of roptare. Brenner found only 59 examples of it among 3,000 cases of hernia, and Baumgartner, in a review of the literature up to 1904, was able to collect only 159 cases. In the present paper Demel discusses 20 cases which occurred in Professor Eiselsberg's clinic at Vienna between 1900 and 1920, during which period 1,474 cases of inguinal hernia and 241 of femoral hernia attended the clinic. Like inguinal hernia, sliding hernia may be congenital or acquired. In the congenital form, according to Baumgartner, ascent of the testis plays an important part, as the large intestine is drawn down owing to its firm attachment to the testis. Acquired hernias are produced either as the result of an attachment of the large intestine to the retroperitoneal tissue, or develop secondarily by the pull of neighbouring coils of the small intestine lying in the hernial sac. The frequency of sliding hernia increases with advancing age, especially after 50. It occurs almost exclusively in men, only 10 of Baumgartner's 159 cases and 1 of Demel's 20 cases being in women. In the great majority of cases sliding hernia belongs to the indirect form of inguinal hernia. In 10 of Demel's cases it was situated on the left side, in 4 on the right, and in 6 on both sides. While in most of his cases the sigmoid flexure was found in the hernial sac, a study of the literature shows that the caecum is the organ most frequently met with in the hernial sac, the sigmoid flexure being next in frequency. Most of the cases of sliding hernia are not recognized until operation. Incarceration may occur as in other forms of hernia, having been found in 44 of Baumgartner's 159 cases and in 3 of Demel's cases. When the appendix forms part of the contents of the sac symptoms of appendicitis may develop, as in 4 of Demel's cases and in 17 of Jiann's 112 cases. Treatment consists in partial resection of the hernial sac and replacement of the segment of the large intestine into the abdominal cavity. Resection of the large intestine is seldom necessary. Of 501 cases of sliding hernia on record 14 were fatal—a mortality of 2.8 per cent.

412. Diagnosis of Peritonitis in Infants.

DENZER (*Amer. Journ. Med. Sciences*, February, 1922) describes a method of diagnosing peritonitis and peritoneal transudates in infants by means of abdominal puncture with the capillary tube. The instrument consists of a trocar-cannula and glass capillary tubing. The shaft of the cannula is half an inch in length and of 17 gauge. The capillary tubes are made from glass tubing 4 mm. in diameter drawn out in a flame so as to fit the proximal part of the shaft of the cannula, impinging upon its wall at the shoulder and protruding 1 or 2 mm. from its end. After sterilization of the skin the point of the trocar-cannula is inserted into the peritoneal cavity, and when the trocar has been withdrawn the capillary tube is inserted as far as it will go. When fluid is present it will rise up the tube and be available for culture, etc. Any place in the abdomen, except over a solid viscus, is suitable for puncture, but the usual site chosen is in the mid-line just below the umbilicus. Besides the detection of fluid in peritonitis peritoneal fluid was found by this method in seven out of twelve infants suffering from marasmus, and in four out of eight cases of rickets, a finding not previously recorded. Notes of five cases of peritonitis are given in which the method was of service in establishing the diagnosis, which often presents peculiar difficulties in infants in whom the classical signs and symptoms may be absent or difficult to elicit.

413. The Pathogenesis of Gastric Ulcer.

BRISOTTO (*Rif. Med.*, February 6th, 1922) criticizes the various theories put forward to explain the formation of gastric ulcer. Hyperchlorhydria is not the primary factor, nor sufficient by itself to explain the pathogenesis of the ulcer. Nor will the vascular theory suffice, all the more since the gastro-duodenal arteries are rich in anastomoses. The inflammatory hypothesis will not explain why the ulcer is of neurogenic nature. Traumatism is not a satisfactory explanation. The single neurogenic theory is rather more satisfactory, as trophic lesions follow affections of the vagus; and if to this is added the influence of the endocrine glands, especially the suprarenals, in trophic changes, through the vagus and sympathetic, a cause which unifies the various adventitious causes may perhaps be found.

414. The Relation of Headache to Functional Monocularity.

SNELL (*Arch. of Ophthalmol.*, January, 1922) studied the relation of partial or complete functional monocularity to the prevalence of headache in 1,010 cases. These were considered in four groups: (1) Absolute monocularity, which showed the lowest percentage of headaches (2 per cent.); (2) anisometropia (4.1 per cent.); (3) amblyopia (8 per cent.); and (4) strabismus (10 per cent.), thus giving a smaller percentage of headache in proportion to the greater degree or completeness of monocularity. Comparison with 1,010 cases with good binocular vision shows that severe or habitual headache occurs seven times more frequently in these than in those with monocular vision. This is explained by the fact that the monocular patient experiences less nervous or brain fatigue, his visual act being less complex, because of the elimination of the fusion sense and the co-ordinate muscular adjustment necessary to maintain binocular vision.

415. Acute Infections of the Nasal Vestibule.

HURD (*Med. Record*, January 21st, 1922) points out the possible danger of acute infections of the sebaceous glands and hair follicles of the nasal vestibule ending fatally by extension through the venous channels to the cavernous sinuses. Swelling of the lids, chemosis, pupillary changes, deep-seated headache, commencing ptosis and exophthalmos, lachrymation, and congested retinal veins following a vestibular infection point to cavernous sinus thrombosis. Treatment of the initial condition by wet dressings and a small incision to avoid opening up the surrounding area, followed by suction and filling the cavity with bismuth paste, is recommended, and the swelling should not be squeezed for fear of rupture into subcuticular tissue. Ligation of the anterior facial vein near the inner canthus, and above the deep facial vein at the anterior border of the masseter muscle, is advised if the infected area is increasing or there are symptoms of cavernous involvement.

416. Paralysis of the Recurrent Laryngeal Nerve after Thyroidectomy.

BÉRARD (*Lyon Chirurgial*, January-February, 1922) points out that the nerves most liable to injury, in operations on the thyroid, are the recurrent laryngeal. These may be damaged at two places and at two distinct times during the operation. The nerve trunk or its branches are sometimes caught during ligation of the inferior thyroid artery, whilst these same branches may be damaged or cut during the dissection of the posterior border of the gland, as they lie alongside the trachea and thyroid cartilage. Besides the effects of crushing or pulling on the nerves, one has seen lesions produced by strong antiseptics, and less often their compression by scar tissue. This may result in a localized paralysis of the muscles of the vocal cords or extend to the whole larynx, including the epiglottis, when the trunk of the nerve has been cut. Rarely the pharynx and oesophagus may be involved in the paralysis. These nerve lesions were common before the technique of the operation was properly carried out. As far as the post-operative paralyses are concerned, without division of the nerve, they depend on the exposure of the nerve trunk, of pulling on it, or its compression between forceps where there is injury to some of the nerve fibres only. The constrictor muscles are usually affected, and these muscles are generally the last to recover after wounds of the nerve. It is impossible to tell immediately after the operation what the ultimate result will be. In order to avoid injury to the nerve, some tie the thyroid artery close to the gland so as to escape the nerve. Others always find the inferior thyroid artery at the point where it passes behind the carotid and tie it with a single ligature. The writer thinks enucleation of the gland within its capsule is the best method of avoiding injury to the nerve. In cases where paralysis of the nerve appears after operation laryngoscopic examination should be carried out. Some cases which appear to undergo spontaneous cure are due to a marked displacement of the unaffected cord towards the middle line.

417. Tuberculous following Circumcision.

WOLFF (*Deut. med. Woch.*, January 19th, 1922) adds two cases to the fifty-eight already published of tuberculosis following circumcision. A study of these publications showed that, in the first six months of life, the prognosis is better for infants infected through the foreskin than by inhalation of tubercle bacilli, the proportion of survivors in the first instance being 37 per cent., and in the second instance only 14 to 16 per cent. Half the deaths following tuberculosis after circumcision in the first year of life appear to be due to secondary infection of fistulae connected with the inguinal glands and not to tuberculosis itself. The treatment recommended is energetic x-ray therapy and aspiration of suppurating glands followed

by the injection of iodoform glycerin, instead of free incision. One of the author's cases shows that this tuberculous lesion is apt to be taken for a chancre.

418. Fracture of the Semilunar Bone.

MOUCHET (*Bull. et Mém. de la Soc. de Chir. de Paris*, March 7th, 1922) reports two cases of fracture of the semilunar bone. He points out that the traumatism is often slight. In one of his cases the patient was engaged in planing, and the plane being suddenly stopped in the middle of its course he felt a sudden pain in the right wrist. In this case it is probable that the periarticular muscles being strongly contracted, the scaphoid was immobilized, and broke under the shock. The patient thinking it was a simple strain continued working for several days. In the second case a blow on the hyperflexed hand caused the fracture, and the loss of function was more marked from the first. In this case the patient was away from work for forty days. With regard to symptoms, one patient, thinking it was a sprain, remained at work and did not become anxious as to his condition until two years later on account of the persistent pain. In the second case the disability was more marked since the patient rested for forty days, but the diagnosis of fracture was only made by x rays three years later. This frequently happens. If the patient is seen some time after the accident the physical signs are not marked—slight shortening and slight increase of the antero-posterior diameter of the wrist and pain on pressure over the scaphoid. Pain and limitation of movement often are the only symptoms. It is a curious thing to see the pains return, sometimes a long time after an accident, when the patient has forgotten the injury—pains persistent enough to suggest an arthritis. The diagnosis is made solely by x rays. Treatment does not usually necessitate surgical interference. Rest and radiant heat are enough in most cases of old fracture. It goes without saying that if the pain and functional inconvenience are very pronounced, removal of the bone will be necessary.

OBSTETRICS AND GYNAECOLOGY.

419. Action of Emetine on the Uterus.

MARTIN (*Amer. Journ. of Obst. and Gynec.*, March, 1922) suggests a cautious testing of the action of emetine in the treatment of metrorrhagia and menorrhagia. In experiments with the excised uterus (immersed in Locke's solution) of dogs, rats, and rabbits he found that in concentrations of 1 in 10,000 to 1 in 100,000 emetine hydrochloride caused a decrease in tone and in amplitude of the rhythmic contractions, together with an increased contraction rate. Injected intravenously in dogs or rabbits, emetine caused, however, an increase of the uterine tone, but given subcutaneously in large doses to rats it did not appear to act as an abortifacient. In the first two series of experiments the results were similar whether the animals were pregnant or non-pregnant. The cause of the different action of emetine *in vivo* and *in vitro* is obscure; the results did not appear to be modified in animals in which the ovaries or adrenals had been removed.

420 The Relation of Ovarian and Endometrial Cycles.

SZYMANOWICZ (*Gynéc. et Obstét.*, v, 1922), from the study of the uteruses and ovaries removed at operation from patients in whom menstrual chronology was normal, the ovaries were free from fibrocystic disease, and endometritis was absent, is able to give the following description of the endometrial and ovarian cycles. The endometrium shows in the post-menstrual phase a thin pale mucosa, of which the epithelium is medium or low, and the glands show few spiral formations. In the next period, or inter-menstrual interval, the thickness of the mucosa becomes progressively increased and the glands are found to be more closely packed and to become more spiral; towards the fifteenth day after the beginning of menstruation the first traces of mucous secretion are perceptible. The third, or pre-menstrual phase, commences about the twentieth day: the mucosa becomes still thicker, the glands show an intensified "corkscrew" form, mucus becomes abundant, especially in the deeper portions of the glands, and the connective tissue cells in the superficial zone become considerably larger, taking a polygonal form which causes them to resemble decidual cells. During the fourth phase, that of menstruation, there is vascular engorgement and apoplexy with destruction of the superficial zone. The Graafian follicle increases in size throughout the inter-menstrual interval, reaches its maximum about the eighteenth day, and ruptures on the nineteenth, when the corpus luteum commences its development. The corpus luteum reaches its best marked phase in close proximity to the commencement of menstruation, and its regression continues through the post-menstrual period. The author has counted the mitoses in the uterine glands during the various phases of the endometrial cycle, and finds that

injected into two normal monkeys. Each of these developed typical measles, and from one of them the disease was passed on to three more monkeys. The interest of the present observations lies in the demonstration of the infectivity of the blood in the early stage of measles, the material having been taken from the patient on the very first day of illness.

A STUDY OF 77 strains of pneumococci is furnished by URQUHART (*Journ. R.A.M.C.*, March, 1922), who has devoted a considerable amount of attention to the correlation of the serological types observed in this country with those encountered in America and in South Africa. For the differentiation of the pneumococcus from other organisms he lays most stress on the positive bile solubility test and the negative haemolysis test. Fermentation reactions, he concludes, are useless. Of the 77 strains studied, 53 were obtained from cases of lobar pneumonia; of these, 17 belonged to Type I, 8 to Type II, and 8 to Type IV. The remaining 44 strains, obtained from such sources as bronchopneumonia, meningitis, colds, etc., were relegated 14 to Type I, 3 to Type II, and 27 to Type IV. It will be noticed that no examples of Type III were met with. These results agree with those of other workers, who have found that the majority of cases of primary lobar pneumonia are due to Types I and II, while in other pneumococcal infections the predominating organism belongs to Type IV.

An Address

ON

THE TREATMENT OF PARALYSIS IN CHILDREN.

DELIVERED TO THE SECTION OF DISEASES OF CHILDREN
OF THE ROYAL SOCIETY OF MEDICINE,

BY

SIR ROBERT JONES, K.B.E., C.B., CH.M., F.R.C.S.,
PRESIDENT OF THE SECTION.

A BODY such as this Section of the Royal Society of Medicine is of inestimable value in bringing together the physician and the surgeon in their manifold activities, and I would emphasize again that a specialism should be attained by a process of mental evolution, and be practised only after a thorough grasp of the fundamental principles of medicine and surgery has been won. Even now there should be a closer association between the work of the physician and that of the surgeon; they are not practising two different arts, and in a large number of cases their combined energies should be devoted to a common end.

On a visit recently with Sir Anthony Bowlby to one of the hospitals in the United States we were impressed by the fact that Harvey Cushing and his class went round the orthopaedic wards with Lovett and his class, and a return visit was paid to the neurological wards. Problems of common interest were discussed and valuable suggestions made. It would be to the common good if physician and surgeon in our teaching hospitals, with their students, could meet in common in the wards. The surgeon, if he is receptive, has always something to learn from the physician, and the physician may sometimes glean a stray idea from the surgeon. Take a group of cases with potential deformity, say the osteoarthritic group. The surgeon with his mind obsessed by deformity is very apt to think that his whole duty is to correct it, and no serious attempt is made to check the infection; while the physician may ignore the slow onset of deformity in his eagerness to discover a microbe. This is all wrong. If we walk round a ward where such cases abound we find ankylosing ankles in full extension, flexed knees and hips, and crooked spines. Yet all these are preventable. The student who becomes the practitioner is encouraged to look upon such results as the inevitable sequence of disease with far-reaching evil effect. A closer affiliation between physician and surgeon would obviate all this; the applied knowledge of each is essential to the scientific conduct of the case. The practitioner in the remote village would then know that such cases have both a medical and a surgical aspect, and as he has to practise both as a physician and a surgeon, the knowledge would relieve him of serious responsibility. Medical sins of omission and surgical sins of commission would both be prevented by a closer affiliation of these great branches of our profession.

I propose to deal with some points in the treatment of the paralyses in children, affections which require the close association of neurologist and surgeon. Poliomyelitis is the most common of the paralytic affections attacking the child, and yet it is not sufficiently emphasized that this affection may not be accompanied by paralysis. Paralysis is incidental, not essential.

The many and very extensive epidemics that have occurred in America, and their careful tabulation by Lovett and others, confirm the conclusion of observers in other countries that there is considerable variation in the onset, although, generally speaking, it is that of an acute infection. I can recall several instances in which I have failed to obtain any history of an acute beginning. In one remarkable instance three children were affected in one family. In one of the children extensive paralysis followed an acute onset; in another the acute onset was followed by pain, but no evidence could be gathered of even a transient paralysis; in the third child extensive paralysis occurred suddenly, with no febrile symptoms and no complaint of pain. In quite a number of cases hyperaesthesia appears before the paralysis. It is difficult to elicit a reliable history of the sequence of symptoms in young children. We are better able to obtain information from young adults; some of them have noted a numbness preceding the loss of power, while others have complained of a burning sensation in the extremities and sometimes of shooting pains. In one case, following a febrile attack, the right leg was affected and, four months later, the

quadriceps of the opposite leg. Such late developments, however, must be very rare.

We are accustomed to look upon the first stage as extending from the onset until all pain has disappeared. If there is no pain, or very transient pain, it is wiser to consider the first or acute stage as lasting six weeks, but so long as pain lasts we must look upon it as indicating active irritation of the cord. I have known the stage of pain to last for nine weeks; in that case, although the paralysis was extensive, it was of a very transient character. Lovett tells us that in America it has proved very necessary that the surgeon should be possessed of the evidence upon which a diagnosis of poliomyelitis has been made. They found it imperative to have recourse to lumbar puncture, because many abortive cases occurred which were potential dangers to the family and State; only in this way could the isolation of the abortive case be secured. It had the further advantage of securing rest in the pre-paralytic stage, and of arousing suspicion whenever a transient weakness was discovered in a muscle or muscle group. We must bear in mind that while lumbar puncture is valuable for diagnostic purposes, it is also a mode of treatment which has proved of benefit in the acute stages of the affection.

The second period usually lasts for two years, and corresponds to the absorptive changes in the cord. During part of this stage the motor area is frustrated in its efforts to send impulses to muscles; in time, however, some of the paths recover and muscular power returns. Even while the power returns, trophic disturbances begin, affecting both circulation and growth, and it is in this period that deformities appear, unless appropriate measures are adopted. The surgeon, unfortunately, too often comes on the scene only in time to correct conditions which should not have arisen, and when preventive measures are too late. The reflex are being broken, the reflexes in the affected area are diminished or lost. The electrical examination of the paralysed muscles is only of value when the tests are carried out by an expert. If the muscle retains its faradic excitability when tested a few days after the onset of the disease, a good prognosis may be given. If, on the other hand, the muscle has lost its faradic excitability, and the response to interrupted galvanic stimulation is slow (the reaction of degeneration), this is evidence of interruption of the lower motor neuron, and the prognosis is correspondingly more grave. From the electrical examination at this stage no accurate prognosis can be given as to the ultimate fate of the affected muscles. The difficulties of diagnosis during the stage of onset are sometimes complicated by pre-existing conditions, such as shortening from fracture, congenital dislocation of the hip, infantile hemiplegia, and in one very interesting case I remember the spasmodic conditions of the limbs due to spastic paraplegia were considerably modified by a superimposed poliomyelitis.

In the early days of treatment it is usually impossible to state the degree of shortening which will ultimately persist. It is very rare to find a shortening of more than three inches. The shortening is not definitely proportionate to the degree of residual paralysis, but bears a closer relation to trophic changes. In one case there was complete paralysis of the right leg and a mere paresis of the left quadriceps, yet the left leg was an inch shorter than the right. In another instance a paralysis confined to the calf muscles resulted in a limb with two and a half inches of shortening. It is equally difficult to foretell the degree of recovery of function. Although it is unusual, I have seen cases in which a muscle has only begun to improve after three years of complete paralysis. When the stage of onset and tenderness is protracted, recovery of the muscles is usually postponed, but the improvement continues for a longer period. Lovett has pointed out, and I can confirm it from my own observation, that cases which present a fairly complete paralysis below a definite level are unfavourable, and that cases which have a considerable amount of total paralysis persisting after three months will only make a very partial recovery. There are, however, notable exceptions.

TREATMENT.

Intimately connected with the question of prognosis is that of treatment, which very largely influences it. From the onset to the end of the second stage, and even later, we have to avoid meddling methods, and to recognize that muscles we are apt to look upon as paralysed may after all be merely weak. I pointed out, many years ago, that a muscle exhibiting the reaction of degeneration is not necessarily outside the pale of hope, and that while we may be certain that if

a muscle reacts to faradism it will recover the converse does not always hold. Prognosis is more hopeful if from the first we visualize the obstacles to recovery and avoid them.

Rest.

The early treatment of poliomyelitis is usually the responsibility of the general practitioner, who has to direct the case on correct principles. During the stage of onset we must trust entirely to rest, and even then protect the muscles which are weak and obstruct the coming of deformity. The head and spinal column should be kept absolutely at rest in obedience to the general law as applied to inflamed structures. Rigid fixation of the head and spine is a relief to pain, but if the pain is slight for physiological reasons rest is imperative. The appliance should be easy and so constructed that nursing is rendered harmless, and nothing should be allowed to take place which might conceivably frighten the child. Body and mind should be kept at rest. While active mischief is present in the cord electricity and massage should be avoided. It is not physiological to irritate and stimulate peripheral ends of nerves connected with inflamed centres. The practice is irrational, cruel, and reactionary. Applications of heat and cold are equally to be condemned. We are dealing with a damaged cord, which must be zealously guarded from fussy therapy. Deformity must be prevented at this stage as well as at every other, and this can be done without any irritation to the child. We must remember that deformity involves a loss of power both in the contracted and in the overstretched muscle groups. The deformities which we usually have to guard against are: contraction of the feet in plantar flexion, flexion of the hips and knees, adduction of the shoulder, and curvatures of the spine. If the child is on a frame soft pillows can be used to correct other deformities; but again I would repeat that nothing is to be done in any way likely to worry the child. Crying is one of the worst evils to inflict upon a tender head and spine.

Before approaching the second phase of treatment I must beg of you, as I have so often done before, to remember that a muscle which is submitted to stretching will lose its function, and that we must draw a distinction between a muscle paralysed by destruction of its governing cell and a muscle disabled and impotent from overstretching. This was pointed out by Thomas forty years ago. It is the fundamental element in our treatment of the disabled muscle. In poliomyelitis the factors that are at work in abnormally elongating muscles are—unopposed muscular action; the influence of gravity, as in plantar flexion of the ankle; deflection of body weight in walking, such as occurs in the foot when, in paralysis of the tibial group, the patient walks on his inner ankle. I will not spend time in giving concrete examples and proofs; they have on several occasions been supplied in abundance, but, although there is a general agreement with the theory, practice leaves much to be desired. If by stretching a normal muscle for a lengthened period we deprive it of power, how important it becomes that a partially paralysed muscle, struggling for function, should receive a helping hand! It cannot be too strongly stated that a paralysed muscle should be kept relaxed, without a solitary break in continuity, until recovery occurs. This should be done at once, for when the deformities become fixed the contracted muscles become structurally shortened and, in accordance with a well-recognized physiological law, all the tissues on the contracted side participate in the change. From this it follows that, in paralysis of the deltoid, the arm should be kept abducted; in paralysis of the flexors of the arm the elbow should be kept flexed and pronated; when the foot has lost the power of dorsiflexion, it should be maintained in dorsiflexion—and so, in all deformities, the functioning muscles should be stretched and the weak ones relaxed.

The next principle I would emphasize is that as recovery begins to take place the relaxation must be lessened by small degrees, the extent being regulated by the patient's ability to make use of the muscle in the extended range. There is yet another important fact—namely, that if a muscle is over-exercised it will begin to lose power. I have met with many instances where a recovering muscle has lost all its power when it has been given its liberty too soon. We must therefore be careful not to overtax a weak muscle. Cases are continually occurring where recovery ceases in a muscle asked to do more work than it is physiologically capable of doing.

In this second stage we are constantly called upon to correct deformity which, as we know, if left may deprive the

lengthened muscle of all hope of recovery; but we must also remember that the shortened muscle is also weakened, because its range of movement is necessarily confined to a limited radius. I will not enter into details of the methods employed to correct deformity; it is enough to say that it can be done by a splint and bandage, and that in the lower extremities we secure the assistance of gravity. Excepting in extreme instances the knife is never needed. The correction is called for in the case of the lower extremities in order to enable the patient to stand and walk with or without assistance, and to attain this end without the production of secondary deformities. In the case of the upper extremity, deformities are corrected mainly in order to obtain function.

Massage.

As soon as the patient is made straight, we devote our attention to the development of his muscles. This is a long and arduous task and too often becomes a routine. "Give the child massage" is often the prescription, as though it were a dose of castor oil. Our aim is to develop the weak muscles and not the strong ones, and yet massage and exercise as usually practised bring into play most prominently the muscles which we should desire to neglect. It is the duty of a physician or surgeon to instruct the masseuse as to her line of conduct, and to explain to her what is needed, and why. We then obtain intelligent co-operation. We shall then know that the muscles will not be fatigued, and that while they are massaged they remain in a position of relaxation and that all the movements are of a kind not calculated to strain the weak group. If the extensors of the wrist are weak, the wrist-joint will be kept dorsiflexed and not once allowed to move in the direction of plantar flexion. If the dorsiflexors of the foot are under treatment, the foot should never be plantar-flexed below the right angle; and both in the wrist and foot the fingers and toes should be actively exercised before an attempt is made to move the heavy joints.

Colin Mackenzie, in his suggestive work on the action of muscles, emphasizes the necessity of minimizing strain on weakened muscles during their re-education. A man suffering from a recovering deltoid, who cannot elevate his arm beyond a right angle when he stands erect, and is opposed by gravity, can complete the range of movement if he lies on a flat table covered with chalk in order to avoid friction, and so with the other groups. By this means very early voluntary effort becomes effective. The splints during this period should be so designed that no pressure on muscle can take place, and, where possible, massage should be practised without their removal.

Muscle Re-education.

Muscle training is of extreme value. It is based on the principle of concentrating the patient's attention so that brain cell and muscle will work in accord. Everything should be eliminated which interferes with the untrammelled action of the paralysed muscle, and when the slightest response follows an effort the enthusiastic expert will almost supply the patient with energy to persevere.

We can perhaps best illustrate this in the case of a limb with paralysis of the quadriceps. Very slight voluntary movement should be started early, but that movement should not be allowed to act on the joint, for the muscle is not strong enough to act against any such resistance. The knee, therefore, is kept fixed in full extension in order to rest the quadriceps. The first sign of recovery will be watched for, and the moment a voluntary twitch is observed education is to be commenced. The masseuse teaches the patient to practise drawing up the patella. When this can be done, she is then told to put her finger against the upper border of the patella and to give a little resistance to the action of the muscle. To allow the child to flex her knee at this stage would be to invite calamity. When the muscle has gained considerable strength the rigid splint may be changed for one that allows only a few degrees of flexion, and as soon as the patient has muscular control of the knee within that radius the range of flexion can be increased by degrees. The massage should be gentle in these early stages, for considerable damage is done if rough. All we can expect from it is an improvement in the nutrition of muscle. I could give scores of instances where recovering muscles have weakened by fatigue from immoderate exercise and from energetic massage. Recovery from this is brought about by rest. My experience coincides with that of Lovett, who has drawn attention to the dangers of overexercising a weak but recovering muscle. He instances the gastrocnemius muscle:

"a normal gastrocnemius should be able to raise twice the body weight; if it is reduced to one-quarter of its normal strength by a paralysis it is easy to see that walking is a continued overstrain of this muscle. Nowhere have I seen the effects of overfatigue more clearly exemplified than in the observation of this muscle. If the muscle is protected, much walking prevented, and a very high heel put on to throw it out of action, as a rule it is amenable to treatment, and I have seen instances where in a year or so the muscle returned to its full normal strength; but I have never seen a case of any considerable weakening of the gastrocnemius muscle do otherwise than badly when walking was allowed freely and the leg not protected by a high heel." This is all borne out by examples we commonly see where paralytics who are undergoing intensive treatment make no progress until they are laid up by some other affection, and the muscles instead of deteriorating gain considerable power. Experience justifies us in concluding that exercise without weight-bearing should be continued until the muscles have gained considerable strength, and that when the time for walking comes it should be regulated with scientific precision.

Electrical Stimulation.

I have spoken of rest, massage, and muscle re-education, and these are the means which appeal to men of the greatest value; but electrical stimulation is a legitimate and useful means of giving certain muscles a mild and beneficial exercise, and the object of the treatment is to make the muscles contract. It is harmful as well as useless to immerse the affected limb in a bath and allow the current to pass through the water. If any action results it will be contraction of the normal muscles and stretching of the paralysed ones.

During the convalescent stage until there is recovery of faradic excitability interrupted galvanic stimulation is employed. It should be possible in a majority of cases for a specially trained masseur, loyal to instructions, to stimulate the paralysed muscle to contract without the spread of the stimulus to the normal ones. Faradic stimulation is of service only with recovering muscles which will again react to this form of stimulus, or for those muscles weakened but not paralysed. Fatigue must not be brought on; the electrically provoked exercise must stop short of this. It should be painless, or practically so, and not cause terror to the child. If it does, it should be discontinued. For reasons that are obvious a paralysed limb should always be kept warm.

Correction of Deformities.

As the object of treatment is to secure for the patient the highest possible degree of function we must prevent or obliterate all deformities. Deformities are primarily due to the contraction of muscles; other preventable factors assist. Although they can be rectified at any stage their persistence through the early months will have inflicted very serious damage to the weak muscle groups. I have seen marked contractions of the hips in five weeks after the onset, and of all deformities, if allowed to become fixed, they are the most difficult to deal with—if we exclude scoliosis—and are a prolific cause of secondary deformities. They occur with greatest certainty where the glutei are weak and the flexors retain some power. They are favoured by sitting and crawling, and are best treated by the use of a double frame, so that the stretching may be continuous. Treatment by posture, such as lying on the face, is less effective, as it is intermittent and violates the fundamental principle we have enunciated in regard to the stretching of muscles. The same criticism applies to scoliosis. There is no position like the recumbent one until the maximum of recovery is assured.

Shoulder contractions are also obstinate, and are due to paralysis of the deltoid and overaction of the pectoralis major and latissimus dorsi; the arm should be abducted from the first, and if adduction has occurred the deformity may be corrected by stretching and an abduction splint applied, as advised by Colin Mackenzie. To see a paralytic child, unprotected, sitting or lying in a heap is a pathetic instance of surgical ignorance or neglect. Deformities, where possible, should be rectified by mild and persuasive means, but there is no excuse in these days which can be accepted to explain either their occurrence or continued existence. Much can be learnt from the gait of paralytics, as so well described by Lovett. When the gluteus maximus is paralysed we find that when weight is borne on the affected side the body is thrown back with a sudden lurch and the patient hurries with the other leg. It is like that of a patient with an amputation of the

upper third of the thigh wearing an artificial leg. Paralysis of the adductors does not cause much limp, but it can be detected by asking the patient to put one foot directly in front of the other. With weak adductors this can only be done by swinging the body.

If the hip flexors are involved the patient brings the affected limb in front by a forward twist of that side. In paralysis of the quadriceps one of several methods may be adopted. He may keep the knee from flexing as he walks by pressing the thigh back with one hand, or as the affected limb touches the ground the patient hyperextends the knee to lock the joint; both these practices produce genu recurvatum. Again, he may walk with his leg rotated outwards to avoid the action of gravity; if he has strong hamstrings he can lock the knee without fully extending, simply by bending the whole body forwards.

The gluteus medius, an antagonist to the adductors, draws the thigh outwards when the pelvis is fixed, or abducts the trunk when the thigh is fixed. Its paralysis causes a characteristic gait. When the patient bears weight in walking on the affected side he inclines over to that side in an attempt to balance, and the lameness is often indistinguishable from that caused by marked shortening of the leg. Lovett has shown us that the limp is largely obliterated during the examination by giving the patient a weight of five to fifteen pounds to carry in the hand of the affected side. It changes the centre of gravity and compensates for the weakness of the muscle.

With weak abdominal muscles the patient stands and walks sway-backed with the hip flexed, marked lumbar lordosis, and prominent abdomen. Unilateral paralysis of the abdominal muscles causes the patient to drop the pelvis on the weak side in taking the weight on the good leg. It is similar to the position taken by a patient with congenital dislocation of the hip when standing on the affected leg. I need not describe other gaits, but it will be seen that by observing the patient's walk the more characteristic paralysees may be noted.

In the third or chronic stage, when all the recovery we can expect has occurred, the surgeon's task is one of restoring his patient to usefulness. The correction of deformity is absolutely essential, for no muscle can be restored unless this is done, and from the mechanical side it is impossible to walk with joints flexed or hyperextended. Of the methods by which we correct various deformities I need only say they are simple. That our present methods will be improved is a commonplace, but there is no reason even now that paralysis should be followed by deformity, except scoliosis, and there is no reason why, if deformity has been allowed to appear, it should not be corrected by one of many means at our disposal.

Splints are used for three objects—the prevention of deformity, the correction of deformity, and to assist the function of the upper arm or locomotion in the lower limb. They should be simple in design and made of light material only just sufficiently strong to effect their task. They must be looked upon as the lesser evils, and when they can be safely discarded they should. In the lower limb apparatus is indicated if the patient cannot walk so well without such aid, or if he can only walk or stand in a position of deformity. When a splint is applied, we must carefully note whether it so prevents or induces secondary deformities. But granted that apparatus in itself is undesirable, the conditions which it is put on to prevent are still more undesirable. These are inability to walk, the acquirement of malposition and permanent deformity, and the stretching of paralysed muscles. We must remember that deformity starts as a postural malposition, becomes fixed by adaptive changes in the soft parts, and progresses to permanent bony deformity in accordance with Wolff's law. These deformities are of every type—dislocation of the femur, knock-knee, genu recurvatum, flexed joints, subluxation of the tibia, contracted and dropping of the shoulder, and scoliosis.

When we come to a general consideration of operations we find they are of two types: one to stabilize a flail joint by operation on the skeleton, the other to restore muscular balance. Our views on the value of arthrodesis have been modified of late years as the result of the introduction of other methods. In the knee-joint it is never necessary in children, and but very rarely in adults. The inconvenience of a stiff knee is a serious one, and the problem is better dealt with by the application of a splint which will permit of flexion. The same may be said of the hip. Arthrodesis of the ankle yields at best an imperfect functional result, and although, perhaps, at times desirable in adults, it is contra-

indicated in young children, and less desirable in older children, than other methods at our command. Arthrodesis of the astragalo-calcanean joint, so performed as to correct any lateral deviation in the foot, is proving of increasing value, for excessive lateral mobility without stability is difficult of control by mechanical means. Arthrodesis of the shoulder is of considerable advantage when the deltoid is irrecoverable and the function of the rest of the arm is good. Before it is performed the muscles of the shoulder girdle must be working, as the object of the operation is to fix the head of the humerus into the glenoid at an appropriate angle so that the arm may be moved by the scapular muscles. In children over 10 the scapular movements become very free as they grow up, and after an arthrodesis the arm can be placed to the back of the neck, and into the trouser pocket. This operation should be but rarely performed in the adult, and its limitations should always be fully described to the patient.

In a technically successful operation in an adult the patient was dissatisfied with the result because previously she could do her hair and fasten the back of her dress by placing the paralysed arm in position with the other, whereas after the arthrodesis the inability to mobilize the scapula sufficiently in adult life prevented the extremes of motion required in these two movements. As a preliminary to arthrodesis of the shoulder intensive exercises for the scapular muscles are needed, and unless the patient can shrug the shoulder with considerable power arthrodesis is contraindicated.

If an arthrodesis is performed on the adult the arm should be fixed in abduction at a lesser angle than in the case of a child. In the child the scapular movement can be considerably increased over the normal range during the years of growth. In the adult there is a danger, if the abduction is extreme, that the arm cannot be brought to the side. This is a very serious functional result.

Tendon transplantation is beginning to appear in its true perspective, and the complicated operations in vogue some years back are no longer performed. Its object is to improve or to restore muscular balance, and it is to be condemned unless it is performed with a reasonable chance of improving function. The transplanted muscle should become a true substitute for the muscle which is paralysed. It may be performed in order to prevent or correct deformity, and the recent tendency of surgical practice is to employ it in conjunction with operations designed to improve stability. Its task in that case is not so responsible as when the transplanted tendon is called upon to do the whole of the work itself. Tendon transplantation is a procedure which calls for sound judgement and irreproachable technique.

Every case represents a separate anatomical problem, and it is not indicated unless there are normal tendons to transplant. The question of operation does not arise when the muscles are all partially paralysed. If nothing has been done in order to relieve the paralysed muscles from tension an operation is not justified until relaxation has been tried, and it is fundamental that all deformity should be fully corrected before a transplantation is done. Naughton Dunn of Birmingham has lately made a distinct advance in the treatment of paralysed feet which require apparatus, by shortening and stabilizing the foot. The operation consists of arthrodesis of the astragalo-calcanean joint and the removal of various portions of bone from the tarsus, retaining the function of the ankle-joint and fortifying plantar flexion by transplantation of the muscles which pass to the sole into the tendo Achillis. I examined some fifty cases upon whom this operation had been performed, and the results were excellent, most of the patients walking without apparatus.

Associated with the success of tendon transplantation is the recognition of those principles which bear upon the relaxation of muscle and fatigue. Any attempt to overwork a transplanted tendon results in weakening it, and until it gains strength it should be treated as if it were partially paralysed. Massage and re-education should be conducted in the absence of weight-bearing.

With improved technique the operation of tendon fixation has gained in surgical esteem, and has made much headway since Tilanus introduced it, much of the improvement being based on the experimental work of Gallie. It consists of the utilization of paralysed tendons as ligaments. The success depends largely upon the anchorage being made very near the articular ends of bone on both sides of the joint, so that a very short piece of tendon is under strain. For instance, in paralytic foot-drop, the tendon of the paralysed calf muscles is divided and the lower end split longitudinally, one half

being brought through the tibia and the other through the fibula, with the foot kept at a right angle. In this way we form a very firm ligament, which prevents dorsiflexion of the foot. These fixation operations have supplanted the employment of silk ligaments, but the practical point wants emphasis—that it is essential the tendons should be fixed just above and below the joint, in order to minimize the danger of stretching. More lately free fascial transplants are being used to form ligaments, but our experience is not sufficient to allow a considered judgement.

The tendency of modern surgery is to stabilize the ankle, and the surgeon calls to his aid a variety of methods. If he deals with a calcaneo-cavus where only the flexors of the toes are working, and perhaps the peronei, he first performs arthrodesis of the calcaneo-astragaloid joint to give lateral stability, and then of the front of the foot, shortening it at the same time. He does not touch the ankle-joint. The peronei and flexors of the toes are passed through the back of the os calcis. If the muscles are weak and will not bear the full strain of body weight, the lower portion of the impotent tendo Achillis is transformed into a strong ligament. In short, he employs arthrodesis to shorten the foot so that leverage is rendered less harmful, and to prevent lateral instability; he employs tendon transplantation to supplant a paralysed calf muscle, and he limits the movement of the ankle by a tendon fixation in order that the transplanted tendons may be saved from fatigue. This is excellent team work, in which all the structures of the foot participate. For pronounced knock-knee, so often found in neglected paralysis, subcutaneous osteotomy is sufficient.

The deformity produced by shortening can now be overcome by an operation devised to lengthen the femur, just in the same way as we lengthen a tendon. If the shortening is the result of a paralytic dislocation the displacement can be reduced and the capsule plicated. In fact, there is no deformity to be met with that should baffle surgical art. Operations, however, are but incidents in the treatment of paralysis, and it is upon recognition of sound principles in the after-care that we depend for the restoration of function.

Nerve transplantation, which at one time seemed so reasonable, is no longer practised, and our observations during the war upon nerve transplantation in paralysis of the peripheral nerves confirm us in discouraging it in infantile paralysis. The direct neurotization of paralysed muscle is only in its experimental stage, and the result will be followed with great interest and considerable misgiving.

My apology for bringing before so learned an audience these elementary but practical principles is that I fear that, even in high places, men are content to give them a mere academic homage.

The Milroy Lectures

ON THE

INFLUENCE OF INDUSTRIAL EMPLOYMENT UPON GENERAL HEALTH.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON ON MARCH 9TH, 14TH, AND 16TH, 1922,

BY

MAJOR GREENWOOD,

READER IN MEDICAL STATISTICS IN THE UNIVERSITY OF LONDON;
FORMERLY STATISTICIAN TO THE LISTER INSTITUTE.

LECTURE II.

I HAVE pointed out the difference between the courses of the death rates at ages in England and Sweden through the last sixty years, how greatly our mortality has improved both absolutely and relatively to that of Sweden in the younger age groups, how unfavourable is the comparison at later ages. Our later adult mortality was indeed still deteriorating relatively to that of Sweden as recently as 1890, and a subsequent improvement has only brought it within 42 per cent. of the Swedish rate. Nor if we compare typical districts of England can it be said that the regions with a high initial rate, such as Lancashire, have improved much faster than those, such as the South-Western Group of Registration Counties, with an initially low rate. If the comparison be extended to other countries the same conclusion is reached, that expressed by Dr. Stevenson in the following words:

"Considering the whole country as a single area of urban type in comparison with other countries the same feature is observed. Our position is relatively very favourable in early adult life, and

very unfavorable when the middle of life is past, and particularly at 45-65." (Supplement to Seventy-fifth Annual Report of the Registrar-General, Pt. III, p. xxxiii.)

Bearing in mind the actual stages of economic development of England and Sweden, it may be said that there is some analogy between the position of Sweden now and that of England fifty years ago. Most of Sweden's economic development has occurred since 1870. In that year only 20 per cent. of her population depended upon industrial pursuits; this proportion had reached 45 per cent. in 1910. Consequently the very high rates of adolescent mortality in Sweden are perhaps correlative with the changes of environment and of survival values which an economic revolution imposes. Such is indeed the opinion of the most competent Swedish writers. The proximate cause of the excessive Swedish mortality is pulmonary tuberculosis (see Table I). At the beginning of the nineteenth century (see Sundbärg, II) phthisis was of the "old age" type, and its frequency in the middle of the century was either stationary or increasing (Rimborg and Sundbärg). Sundbärg thought that the responsible factor was industrialization. Of the increasing mortality at ages 15 to 20 he wrote:

"The cause of this difference between earlier and more recent times seems to us to lie in the fact that formerly the adolescent boy and girl remained at home for a longer time. Nowadays one goes more frequently and at an earlier age to the city or the factory. The new conditions of existence bring in many cases increased dangers to health and life—dangers which, especially in the case of women, often lead to tuberculosis" (Sundbärg, I, 204).

Widell has recently (see *Dödlighets och Lifslängdstabeller för Åren, 1816-1910*, p. 13, and *Dödlighets och Lifslängdstabeller för Årtiondet, 1901-10*, p. 19) affirmed this conclusion.

But there are two important distinctions between the circumstances of England a generation ago and of Sweden now. The first is that Sweden has been an emigrating country—she has lost on balance 843,281 persons in the last fifty years; the second is that Swedish late adult mortality is less than ours is now, and, *a fortiori*, less than ours was a generation ago. Both Sundbärg and Widell think that the decline of spirit drinking has been an important cause of the decreasing mortality at later adult ages. The consumption of spirits reached a maximum in 1871-75, and declined until 1909, since when it has been almost stationary, with, if anything, a slight upward tendency. The cause of the decline seems to be a matter of controversy (see *Sweden*, vol. i, p. 743).

Of the effects of emigration upon the rates of mortality of the home-keeping population I shall not speak in these lectures; they are too complex to be fitly discussed incidentally. The same must be said of a different form of selection—that imposed by the operation of mortality itself. Upon neither subject do my inquiries throw light, yet both must be kept in mind, and I mention them here to warn you against too absolute inferences from the contrasting series of mortality rates which I have examined.

INFLUENCE OF MIGRATION.

But although I am not prepared to discuss the wider aspects of migration, I do desire to examine in some detail one part of a subject to which Dr. Hamer has devoted close

attention (see in particular Hamer, 1912, and Hamer, 1921), because its importance is suggested by the quotation I have just made from Sundbärg.

It is difficult to summarize a connected argument in a few words, but I think the gist of Dr. Hamer's contentions is as follows. So far as concerns the influence of emigration in the popular sense of the term—that is, migration from one country to another—Dr. Hamer thinks that those European countries in which economic prosperity has advanced but which have lost population by emigration and have also experienced a decline in the death rate from phthisis, have parted with a large proportion of their weaker citizens, and he shows that the decline in the phthisis rate has been correlated with an outward movement of population in search of health to Australia, America, and elsewhere. On the other hand, in some countries—notably Ireland, where domestic, social, and economic conditions have been bad—emigration has removed a larger proportion of the healthy young adults, and the death rate from phthisis amongst home keepers has either remained stationary or declined but little. This branch of the subject I shall not discuss, but turn at once to the problematic effect of internal migration. Dr. Hamer has shown (making skilful use of the late Sir George Buchanan's report upon phthisis in Kent, Surrey, and Sussex) that rural districts especially ravaged by phthisis are precisely those which a study of age distribution and of other local circumstances proves to have suffered a heavy loss by downward migration. He has also pointed out the favourable rates of mortality experienced by the urban districts as a whole in comparison with country districts at adolescent ages. Hence he attaches much importance to the lure of the towns for the young, vigorous, and ambitious adolescents. But, it may be said, this goes no way to account for the very heavy excess mortality at ages of maturity in towns. Dr. Hamer, however, remarks that there is a townward trend of immigration at later ages of life, but the quality of the immigrants is different. In adolescence and young manhood it is a migration of the vigorous and hopeful; at later ages it tends to be a migration of those broken in the struggle for life, seeking, not perhaps with much hope, what has hitherto escaped them. The immigration of the young and healthy lowers the immigration of the middle-aged and unhealthy increases, the urban death rate.

I am not quite sure whether Dr. Hamer is prepared to press his theory of the importance of migration as a factor of mortality beyond the point just reached, so that any discredit belonging to the very speculative extension I am about to make belongs exclusively to me, while, should it be found worthy of consideration, the credit is entirely Dr. Hamer's.

It is possible that the change of environment from town to country may have an extremely unfavorable effect upon the immigrants, the supposition invoked by Sundbärg to explain the Swedish experience at ages 15 to 20. Before theorizing about this we may inquire whether the scale of internal migration is large enough to make any supposed effect upon the health of migrants a substantial factor of mortality.

The report of the Census of 1911 (General Report, Cd. 8491 of 1917, pp. 203 et seq.) contains an experimental tabulation of age distribution of immigrants in certain large town boroughs. The age group of greatest immigration proved to be 25 to 35, in which decennium the proportion is of the c

20 per cent. of the enumerated urban population in that age group. In the districts examined it was as high as 22.4 per cent. in the industrial borough of Swindon, 19.4 in Bradford and Burton-on-Trent, 18.9 in the county of London, and only so low as 16.4 in the non-industrial borough of Hastings. If we take 20 per cent., as found in this experimental tabulation, to be a fair characterization of industrial towns as a whole, is there a sufficient supply of country-born persons to furnish the immigrants, or must they be no more than transfers from one town to another?

A precise answer cannot be made to this question, but the difference between actual increase and natural increase of rural districts is very large. Thus, the increase of the *de facto* populations of the registration counties of Huntingdon, Bedford, and Shropshire between 1901 and 1911 was 31,506, the excess of annual births over annual deaths 57,221, leaving an outward balance of 25,715. Numerous examples of urban trends are to be found in Mr. T. A. Welton's book. One cannot doubt that in most manufacturing towns the numbers of country born and bred immigrants are very large, so that Dr. Hamer is almost certainly correct in supposing there to be ample material for the revelation of effects.

In the brief discussion I devoted to the topic in my paper on tuberculosis (Greenwood, 1920) I tacitly and too lightly assumed that the supposedly healthy and ambitious immigrants from the country died in the towns at a lower rate than the town-born coevals and so depressed the average mortality at adolescent ages. I suggest that the very reverse of this may be the truth. A considerable literature has arisen of recent years around the question of bringing "unsalted" populations into contact with urban civilization (Colonel Bushnell's monograph is an admirable introduction to the subject); perhaps what happens to an extreme degree when Dryden's noble savage becomes a townsman happens to a less degree when Corydon repairs to the teneament, the picture palace, and the factory. Adolescent migration perhaps increases mortality in both populations—rural mortality by the withdrawal of those best fitted to survive under the rural environment, urban mortality by the introduction of those ill adapted to survive under urban conditions. I shall show that the mortality at ages 25 to 35 of bootmakers in Leicestershire and Northamptonshire is much greater than that of the north-western cotton operatives, in particular the mortality from phthisis. The statistically rural population of these counties lives under conditions much more closely approximating to what the Londoner thinks of as "country" than does the rural population of Lancashire and Cheshire. But this is a faint argument, and until by such an inquiry as that of Dr. Perry in America we can gather more knowledge of the provenance of factory workers the subject must remain obscure. In any case I do not suggest that migration is all-important. Thus the rate of mortality of cotton operatives passes above that of the Leicestershire and Northants bootmakers at 45, and there can be little probability that the downward movement of failures at ages over 45 has a substantial effect upon the mortality rates of a highly skilled industry such as the cotton manufacture. I have, however, some other relevant facts.

Dr. Miyagima has been kind enough to give me some suggestive particulars respecting mortality in Japan. In that empire mortality from tuberculosis has tended to increase, and in 1901-05 was 50 per cent. higher than in 1886-90. According to the statistics of 1908-12 the excess over English rates is especially noteworthy between the ages of 20 and 30; at 25 the mortality in Japan is more than twice that of England and Wales. According to some investigations of Dr. I. Ishiware, the rate of mortality upon girls employed in cotton mills is especially severe. Annually not less than 210,000 girls are invited from the country districts into the mills, and the annual rate of discharge from ill health is 80,000—that is, more than a third of the numbers recruited (not of course the same individuals). Of the 80,000 discharges, 6,000 are said to be due to tuberculosis, and 70 per cent. of all deaths amongst those discharged are due to tuberculosis. The Government has been led to take special action to deal with the sanitary condition of the factories.

These results are consistent with the hypothesis I have suggested, but naturally a foreigner ignorant of the language and customs of the country is not in a position to make full use of the statistics. The apparent partial immunity of Jews to phthisis (Fishberg) is also a relevant circumstance.

So I must leave this important question with no more than a speculative answer. Yet enough has been shown to justify a closer research. Notwithstanding the bureaucratic interference with the lives of citizens which our newspapers bewail, there is a surprisingly large number of quite simple but important facts which we do not record.

POVERTY.

Sundbärg's remarks upon mortality in Sweden invited this, not, I hope, unseasonable digression. I now return to more obvious subjects of inquiry. A very large proportion of townsmen and women are desperately poor, and the hygienic evils of poverty, the radii of its vicious circles (well described in Dr. Hurry's recent book), smaller in industrial towns than in the country. I will not overstate the case; the eclogues, whether of Virgil or Pope, are not a reliable guide to life even in the shoe-making districts. Many agricultural labourers are wretchedly housed and miserably poor. But the etiological importance of unsuitable housing is so largely a function of density, of mere aggregation, that the hygienic evils of tenement houses which Dr. Wanklyn described in 1913 as constituting a "gigantic tax on the public health," or of the back-to-back houses which Dr. Robertson so recently stigmatized, are essentially town evils. Bad housing, however, is not the only consequence of poverty: low real wages mean the deprivation of other things besides house-room. The housing conditions of a town are not absolute measures of the economic prosperity of its inhabitants.

The question, then, may be asked whether mortality can be adequately expressed as a function of the two variables—housing and real income; if so we need seek no farther. But that the general etiology of the death rate in industrial towns cannot be fully expressed in terms of these two variables is suggested by the researches of Professor A. L. Bowley and Professor Burnett-Hurst. Their inquiry was no doubt prompted by the well-known book of Mr. Rowntree on the industrial conditions of York, but it followed a different plan.

No study on the scale of Mr. Rowntree's, *a fortiori* none such as the late Charles Booth's investigation, can be carried out save at enormous expense of time and money. The method of exhaustive enumeration must be reserved for such relatively simple particulars as are ascertained by a census; in fact, some statisticians hold that the census authorities already ask too much. But if we cannot measure the "universe" we can at least measure a sample of it, and, in a majority of cases, the sample will tell us all we need to know. The theory of the method is expounded in all textbooks of statistics, and its practical application is subject to various limitations, but none of these are of much importance in the particular circumstances of the inquiry I am about to describe.

A Sampling Inquiry.

Professors Bowley and Burnett-Hurst inquired into housing accommodation and economic circumstances in each of the four county boroughs of Reading, Bolton, Warrington, and Northampton (they also investigated the urban district of Stanley, but this district is not comparable with the others from the present point of view). In assessing housing accommodation the census standard was modified. "An adult (including boys over 18 years and girls over 16 years) is counted as one, other boys and girls over 14 as 3/4, children from 5 to 14 as 1/2, and children under 5 as 1/4. The household is then reckoned as containing so many equivalent adults. It is then found on examination that five equivalent adults can be accommodated in a five-roomed house, allowing 500 cubic feet per adult, with a little give and take; and one person or less per room on this basis may be regarded as a reasonable standard of sufficiency" (Bowley, p. 677).

In his work on York Mr. Rowntree adopted a minimum standard of diet and minimum requirements for fuel, clothing, and house rent. The three latter depend on local conditions, the former on physiological evidence. Actually the diets quoted in Mr. Rowntree's book as obtained by his poorest observed class yielded about 2,600 calories per "man" (Greenwood and Thompson), a provision which would now cost at least three times the sum allowed in Mr. Rowntree's scheme—namely, 3s. per week; the theoretical standard was 3,500 calories. Professors Bowley and Burnett-Hurst modified Mr. Rowntree's theoretical food standard by assuming the purchase of two pounds of meat weekly, and this, allowing also for rise of prices between 1899 and 1913, brought the estimated per capita expenditure for an adult to 4s. 6d. weekly—rather less than half of what it would cost now.

"In making comparisons with the standard, it is to be observed that nothing is allowed for insurance (other than State), pocket money, tram fares, beer, betting, newspapers, or any of the other ordinary objects of expenditure other than necessities. On the other hand, we do not reckon profit from allotments (which are numerous in Reading and can provide perhaps a weekly shilling-worth of potatoes, beans, etc., together with less nourishing vegetables), and have, no doubt, omitted small earnings of the school children and wives" (Bowley, p. 685).

The authors, having made the necessary calculations, determined the percentages of working-class families below the poverty standard as just defined; these, and the percentages of overcrowded families computed by their method (owing to certain special difficulties—see Bowley and Burnett-

families below the standard as an average measure of poverty in the economic sense, we see that there is no close relation between mortality and real wages in these towns. Reading, which is by this test far the most poverty-stricken of the towns, has the least mortality at every age. On the other

hand, the two Lancashire towns which (except in the age group 15 to 25) have the worst mortalities have also the most overcrowded dwellings. But the housing conditions of Northampton are better than those of Reading, yet only at ages 25 to 45 (of course, a very important exception) are the Reading and Northampton mortalities upon a par.

It is sufficiently well known that the industries of these towns are widely different. In Reading the principal employer of industrial labour is a great biscuit firm upon which a fifth to a quarter of the working class directly depend (Bowley and Burnett-Hurst, op. cit., p. 160); this branch of manufacture does not need a large proportion of skilled industrial workers. The staple industry of Northampton is the manufacture of boots and shoes, which, with ancillary processes, employs 42 per cent. of occupied males and 43 per cent. of occupied females (after excluding professional occupations, Government employees, and soldiers). Warrington contains some of the largest ironworks in the country, and iron work is by far the largest single industry, but there are numerous other branches of manufacture. Bolton is one of the great textile towns. There is, then, no homogeneity between any two of the towns in respect of industrial processes, but Bolton and Northampton probably employ a larger percentage of skilled industrial workers than the other two cities (in the iron trade alongside of the skilled men there work many labourers on small wages; when the inquiry was carried out many of the latter earned 20s. to 24s. per week of fifty-three hours).

Can we say that there are any obvious conditions common to the highly skilled Northampton population and the lowly skilled Reading population, on the one hand, and not characterizing the highly skilled Bolton and the moderately highly skilled Warrington population on the other? There are some noticed by our authors.

"Northampton," they remark, "for a manufacturing town is remarkably clean; the boot and shoe factories do not require tall chimneys pouring out dense volumes of smoke, and the number of factories from which pollution takes place is very small. Warrington, on the other hand, is at times 'one mass of smoke'" (op. cit., p. 95).

Bolton, although less smoky than Warrington, is nearer to Warrington in this respect than to Reading or Northampton. In Northampton and Reading Professors Bowley and Burnett-Hurst remark upon the plentiful provision of allotments (op. cit., p. 81; Bowley, p. 685). Perhaps we have here a distinction of some importance; I do not mean that the contributions to family supplies derived from allotments—after all only a minority of the working population can cultivate gardens even in Reading—invalidate the authors' economic classifications, but that the general conditions which render gardening possible at all for the working classes may be significant of much. That treeless desert which saddens the traveller by the North-Western Railway, and inspired so much excellent mid-Victorian prose, is not, perhaps, only an æsthetic blemish. Socrates' remark, "Now shall I go on and mention to you also windless air, calm sea, and all that sort of thing, and say that stillness causes decay and destruction and the opposite brings preservation?" (*Theætetus*, IX); has found a brilliant exponent in Dr. Leonard Hill, who has displayed a factor of mortality we cannot neglect.

I do not mean that the Lancashire towns are surrounded by a windless air; I only suggest that the squalid monotony which seems to be the external characteristic of some of our north-western manufacturing towns may promote decay and destruction. This is certainly not the whole explanation. If one considers the details of the death rates, it will be found that the greatest discrepancy between Northampton and Reading on the one hand, and Bolton and Warrington on the other, is under the articles of deaths from pneumonia. At 45 to 65 the Bolton and Warrington rates per 1,000 living were 2.1 and 2.8 on males, 1.1 and 1.9 on females; the Northampton and Reading rates were 0.9 and 0.8 on males, 0.3 and 0.5 on females. But Bolton and Warrington are in the north-western area, while Northampton and Reading are in the south-midland district.

It is notorious that the rate of mortality from pneumonia is higher in the north than in the south of England; that of rural districts in the north is higher than the urban district rate in the south. What portion, then, of the excess mortality from these causes should be debited to climatological factors?

The obvious test is to compare urban with rural mortality in the north-west, but unfortunately the industrialization of Lancashire is so great that the districts which are more than nominally rural contain a very small population. An

unsatisfactory test, but the best available, is to make use of the decennial returns of registration counties.

A comparison extended over a whole decennium is affected by the fact that prior to 1911 the death rates were not corrected for institutions. However, the accompanying table (VI), based on the decennium 1901-10 and comparing

Westmorland:				
Male	0.91	0.19	1.76	0.95
Female	0.56	0.29	0.89	0.53

England and Wales, Lancashire, Northants, Cumberland, and Westmorland, is instructive. If we assume that the whole of the excess mortality in Cumberland above the all-England rate is due to climatological factors and ignore the rates of sparsely populated Westmorland entirely, we see that Lancastrian males die of pneumonia in the age group 45 to 55 26 per cent. faster than the males of Cumberland and 36 per cent. faster in the next age group. They die more than three times as fast as the Cumberland males of bronchitis at 45 to 55 and more than two and a half times as fast in the age group 55 to 65.

Speaking of pneumonia in 1912, Dr. Steverson remarked:

"The range of mortality is extreme, being almost four times as great for males in county boroughs of the North as for females in the rural districts of the South, and three times as great when males alone are compared. Even when comparison is restricted to the same class of area in each case the mortality of the North is in no instance very much less than twice that of the South. No doubt this depends to some extent upon industrial conditions, but these can scarcely explain the great difference between the North and the Midlands. Evidently pneumonia is to a large extent a preventable disease, and the North of England has still much to learn with regard to its prevention" (75th Annual Report of the Registrar-General, Cd. 7028 of 1914, p. xiv).

Time does not permit of other detailed comparisons, but the course of phthisis mortality is interesting. At 15 to 25, Northampton is the worst of the towns (2.5 per 1,000, males, 1.8 per 1,000, females), and, excepting women in Warrington, there is nothing to choose between Reading and the northern towns (Reading 0.9 and 0.9, Warrington 1.0 and 1.5, Bolton 0.8 and 0.9). In the next age group, Warrington is worse, but not significantly worse than Northampton. At 45 to 65 Warrington and Bolton differ considerably from the other two towns (Warrington 3.9 and 1.7, Bolton 2.8 and 0.9, Northampton 2.1 and 0.6, Reading 1.5 and 0.9).

This comparison, while sufficient to make it probable that variations of real wages do not account fully for great discrepancies of mortality—thus refuting the newspaper contention that if we only abstain from national and local taxation for medical and hygienic "fads" all would be well—certainly does not unerringly reveal some one industrial factor in the northern towns which destroys life. Yet these figures do bring to light an important industrial correlation. In the year 1913 Northampton experienced the highest death rate at ages 20 to 25 (males) of any county borough in England and Wales, and at 15 to 25 the death rates for both sexes were much higher than in the other towns of our series. Turning to the causes of deaths, it appears that the phthisis mortality was very high. We certainly cannot explain it by the generally unfavourable sanitary conditions of the town; we have seen that at later ages Northampton stands better than Warrington or Bolton. We may of course say that the low Northampton mortality at 25 to 45 is partly owing to the high and selective mortality at 15 to 25, but it remains to consider what these influences are which make for so high a mortality at the earlier age. The mortality of boot and shoe manufacturers from phthisis is very great, a proportionately great in comparison with their mortality from all causes. Using the comparative mortality figures of the Registrar-General

(1910-12), shoemakers are found to have had a mortality from all causes 88 per cent. greater than that of the clergy; their mortality from phthisis exceeded that of the clergy by no less than 356 per cent.

Dr. Jacques Bertillon summarizes an analysis of thirteen sets of tables in the following words:

"The results of these different tables are sufficiently concordant except the French table, the mortality is average (rather slightly less than average at all ages in the four English tables, the Swiss table, and the Parisian table for 1890-93). It is slightly above the average in the two Scottish tables, the Paris 1885-89 table, and that of Leipzig. It is very sensibly above the average (especially below 35) in the French table. All the tables agree in showing that phthisis is frequent at all ages. Other diseases of the respiratory system are, on the contrary, rare" (p. 171).

The occupational incidence of disease I propose to examine in the next lecture; I mention the case of shoemakers here, since it arises in connexion with our study of the four towns; as perhaps the best instance they afford of an industrial correlation not associated with specially low wages or bad housing.

I have dwelt upon the vital statistics of these four towns because for them alone we have contemporaneous measurements of economic status, and only when such are available over a much wider area can we hope to know the real mass etiology of death rates. The field covered was too small to render it probable that definite hygienic inferences could be drawn. But even this small experiment has taught us much, and suggested that investigations on the lines of Professor Bowley and Professor Burnett-Hurst's inquiries would be of sanitary as well as economic importance—if, indeed, in a civilized commonwealth economic and hygienic interests can ever be separated.

I conclude with a few remarks upon the significance of some wider data.

Working Life.

Hygienists are grateful to Dr. E. C. Snow for devising, and to the late Registrar-General, Sir Bernard Mallet, for arranging the publication of, a long series of sectional life tables based on the experience of the years 1911 and 1912.

It is of course easy to overrate the importance of the life table as an instrument of hygienic research. The beauty of the technical methods used for its construction and graduation appeal to the professional statistician, the symbolical notation in which those methods are (necessarily) displayed strikes awe into the heart of the non-actuarial medical officer, who is apt to suppose that there is a special intellectual prestige attaching to those who can freely utter such mysterious phrases as "curtate expectation of life" or "osculatory interpolation." One sometimes forgets that life-table constants are subject to precisely the same difficulties of interpretation as the death rates themselves from which they are deduced. The life table of any district is based upon the death toll taken of contemporaneously existing lives. Could we make a life table for persons followed individually from the cradle to the grave, the result would probably differ greatly from such tables as we can construct. I am a less enthusiastic admirer of the life table as an instrument of research than is Dr. Brownlee. The life tables we have do, however, answer some important questions.

By the age of 25 the period of apprenticeship is almost over, by 55 the prime of working power in the industrial classes is past. Of the possible term of thirty years here covered what is the average number actually lived in areas of different industrial and geographical types? In the table I provide such approximations to the answer as can be deduced from sectional life tables (the short tables of the General Register Office have been used).

TABLE VII.—"Partial" Expectation of Life for Males during the Thirty Years from Attained Age 25.

NORTH-WEST OF ENGLAND.	
Great Industrial Towns.—Bolton, 26.8; Burnley, 27.3; Halifax, 27.1; Huddersfield, 27.1; Leeds, 26.7; Oldham, 26.5; Preston, 26.6.—Average, 26.9 years.	
Non-Industrial Areas.—County of Cumberland, 27.1; County of Westmorland, 27.7; Rural Districts of the West Riding, 27.5.—Average, 27.4 years.	
SOUTH-WEST OF ENGLAND.	
Industrial Towns.—Bristol, 27.1; Plymouth, 26.4; Southampton, 26.2.—Average, 26.6 years.	
Non-Industrial Areas.—Dorset, 27.8; Wilts, 27.8; Devon (rural), 27.7.—Average, 27.8 years.	
MIDLANDS.	
Industrial Towns.—Coventry, 27.7; Derby, 27.6; Nottingham, 26.8; Leicester, 27.3.—Average, 27.4 years.	
Non-Industrial.—Derbyshire (rural), 27.8 years.	
EAST ANGLIA.	
Industrial.—Norwich, 27.6 years.	
Non-Industrial.—Rural Districts of Norfolk and Suffolk, 27.9 years.	

At a glance such figures as these are reassuring. The difference between the best and worst in the table, between Oldham and the rural districts of Norfolk and Suffolk, is only 1.4 years. But were we able to take them at their precise face value these figures would

be very depressing. The average value of the seven Lancastrian industrial towns is 26.9 years. Between the rural areas of different parts of the country the administrative counties of Westmorland, Dorset, Wiltshire, the rural parts of Norfolk, Suffolk, Devon, and Derby there is hardly any difference—the lowest is 27.7, the highest 27.9, the average 27.8. Therefore every man who passes his productive years from 25 to 55 under the rural conditions will have 0.9 of a year more to live in that productive period than a man of the same entering age in the industrial towns; the urban man power is 93.76 per cent. of the rural man power, defining man power as years of life lived from 25 to 55. Put in other words, were the urban strength, r the rural conditions 16 per cent. of its productive power as now, although these rural samples themselves only yield 92.67 per cent. of the theoretically possible span, thirty years.

As a further illustration, I consider the partial expectation at 23 for the thirty-five years to 55 (males). Having applied the method to the ten industrial registration districts of Stoke-on-Trent, Wolverhampton, Walsall, West Bromwich, Dudley, King's Norton, Birmingham, Aston, Leicester, and Nottingham, and to the agricultural district formed by excluding the registration district of Lincoln from the registration county, the following results were reached:

In 1851-60 the urban man power was 95.7 per cent. of the agricultural man power; in 1901-10 it was 97.1 per cent. of it. Sixty years ago the Lincolnshire males lost 13 per cent. of their possible time, and now lose 8.4 per cent. Sixty years ago the urban males lost 16 per cent., and still lose 11 per cent. (Greenwood, p. 178). Again, I make the reservation that results based upon the mortality of two years (which is the case of the figures used above and referring to 1911-12) have only the value of samples, and are subject to errors of sampling. Space does not permit me to discuss the evaluation of the error of sampling for a somewhat complex expression such as the partial expectation, but I find it to be of the same order as that of the death rates, and there is little reason to doubt that the kind of difference shown in these few examples is of the order of magnitude of the "true" difference.

THE VALUE OF VACCINES IN THE TREATMENT OF WHOOPING-COUGH.

BY

DONALD PATERSON, B.A., M.R.C.P.,

PHYSICIAN TO OUT-PATIENTS, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON.

AND

JAMES M. SMELLIE, M.D. EDIN.,

PHYSICIAN TO OUT-PATIENTS, THE CHILDREN'S HOSPITAL, AND MEDICAL REGISTRAR, QUEEN'S HOSPITAL, BIRMINGHAM.

THE object of this paper is to record some observations on and the results of vaccine treatment of cases of whooping-cough. The majority were out-patients, a few being in-patients, at the Hospital for Sick Children, Great Ormond Street, during the months of January, February, and March, 1922.

For purposes of age and sex incidence we have included all those cases of whooping-cough which attended the out-patient department of this hospital during the year 1921 and the first 196 cases that attended in 1922, making 1,000 cases in all. The seasonal incidence has been taken from the 804 cases attending during 1921.

CHART 1.—Seasonal incidence, 1921. (Based on 804 cases)

As will be seen from Chart 1 the seasonal incidence reached its maximum in June, when there were 109 cases, and fell to the minimum in November, when there were 25 cases. The sex incidence shows 530 girls to 470 boys. The age incidence (see Chart 2) shows the maximum at 1 to 2 years, and the vast majority occur before the age of 6 years, or within twelve months of starting school.

Symptoms.

The average duration of the cough before the onset of the whoop in 100 of our cases seen during January, February, and March, 1922, was two weeks. In some cases the whoop started

within a few days of the onset of the cough, but in other cases was delayed as long as three to four weeks.

The onset, duration, and termination of the whoops and vomits were on the average identical. At the onset the

CHART 2.—Age-incidence. (Based on 1,000 cases.)

whoops were much more severe and frequent during the night than by day. As the disease declined the whoops became gradually less during the night, and in the later stages of the disease were entirely confined to the day.

In very young children gross wasting as a result of the incessant vomiting was a very serious feature, and was of importance even in the older children. Where vomiting was severe obstinate constipation was a concomitant symptom.

A sublingual ulcer was looked for on at least one occasion in 62 cases; it was present in 11, or 18 per cent. In several it was not present at the first examination early in the disease; it was usually found to develop during the second or third week. In 9 of these cases, or 82 per cent., the age of the children was between 1 and 3 years. The ulcer healed very rapidly; a careful and continuous search would, we have no doubt, reveal this ulcer in a much larger proportion of cases.

Bronchitis is present in the majority of cases. The signs may be scattered rhonchi; and early in the disease, almost at the level of the diaphragm, a girdle of fine crepitations is very frequently heard. In small children massive collapse, dyspnoea, and cyanosis sometimes complicated the clinical picture and gave rise to the diagnosis of bronchopneumonia. These physical signs are, in our opinion, brought about by the thick tenacious secretion present in the bronchi plugging the smaller bronchioles of the most dependent parts of the lungs, thus giving rise to collapse in this area with consequent fine crepitations.

In 4 out of 80 cases the tonsils had been removed. In 18 cases there was injection but no enlargement; 18 others showed moderate enlargement with injection; in the remaining 40 cases, or 50 per cent., the tonsils were grossly enlarged and injected. The injection is, no doubt, secondary to the coughing.

Duration.

The average duration of the disease in our 100 cases, as measured from the onset of the cough to the termination of the whoop or vomit, was six and a half to seven weeks, while the average duration of the whoop was four and a half to five weeks.

Complications.

Epistaxis was a not infrequent complication, and was much commoner in older children, though of minor importance. Bronchopneumonia, on the other hand, occurred in 5 per cent. of 200 cases, but gave rise to grave anxiety, 4 out of our 10 cases proving fatal. Among other complications were subconjunctival haemorrhages and laryngitis; puffiness of the face was not infrequent, and in the more severe cases called for an examination of the urine to exclude nephritis. Pain, referred to the diaphragm, the intercostals, and the abdominal muscles, due to the violent straining and coughing, was frequently complained of by the older children. Convulsions occurred only in association with bronchopneumonia, and the two cases we observed both proved fatal. Post-mortem examination in one of them showed on microscopical examination marked cerebral congestion only.

In 5 to 10 per cent. of our cases a fresh attack of bronchitis caused a recurrence of the whoops.

Mortality.

The mortality in 200 cases observed during three months was 2 per cent.; these four cases died of bronchopneumonia, and two of them terminated in severe convulsions.

Diagnosis.

In the earliest stage, before the cough is paroxysmal or the whoop or vomit appears, the diagnosis is extremely difficult. A fretful, peevish child aged 1 to 3 years, with a short hacking cough, possibly laryngitis, slight unexplained pyrexia, and usually a girdle of fine crepitations at the level of the diaphragm, should make one suspect the onset of this disease. Briefly the clinical picture is that of an ill child; the physical signs are comparatively slight.

In the later stages the diagnosis becomes less difficult. The characteristic expiratory paroxysms with whoop and vomit, the slightly puffy face, the subconjunctival ecchymosis, the occasional epistaxis, and the presence of a sublingual ulcer, all point towards pertussis.

We have unfortunately occasionally observed this sublingual ulcer in children of the same age in which it commonly occurs in whooping-cough (1 to 3 years), and in these cases there could be no question of whooping-cough playing a part in its formation. We agree that these ulcers are formed by the tongue striking on the sharp lower incisors during the forcible expiratory spasms of coughing.

In our opinion the whoop is not necessary for diagnosis. In eight families where several children were suffering from undoubted whooping-cough one child was observed to have typical cough without the whoop. On the other hand, a typical paroxysmal cough with a vomit and a whoop may be found in cases of tuberculosis with caseous mediastinal glands. The presence of tuberculosis in other parts of the body and the length of the history may help to clear up the diagnosis. A foreign body in the trachea may also closely simulate pertussis in this respect.

Treatment.

The number of patients treated with vaccine and followed to their recovery was 64. Of these, 6 were given bi-weekly injections and treated as in-patients, while the remaining 58 were given weekly injections while attending the out-patient department.

Dosage of Vaccines.—The vaccine was supplied by a well-known London laboratory, and the dosage we employed was as follows:

Initial injection:				
Bordet's bacillus	500 million.
Influenza bacillus (Pfeiffer)	125 "
Pneumococci	25 "
Second injection:				
Bordet's bacillus	1,000 million.
Influenza bacillus	250 "
Pneumococci	50 "
Third and subsequent injections:				
Bordet's bacillus	2,000 million.
Influenza bacillus	500 "
Pneumococci	100 "

For the purposes of this paper the length of the disease was defined as from the onset of the cough to the termination of the whoop.

*RESULTS.**A. Vaccinated Cases.*

1. In 58 of the out-patient cases treated with weekly injections the average duration was 7 weeks; those treated within the first week of the onset showed an average duration of 5.7 weeks; those in the second week of the disease an average duration of 5.9 weeks; those in the third week an average duration of 7.2 weeks; in the fourth week an average duration of 7.6 weeks; in the fifth week an average duration of 9 weeks.

2. In the 6 cases treated with bi-weekly injections as in-patients the average duration was 6.6 weeks.

B. Non-vaccinated Cases.

The average duration of the disease in 42 control cases that were not treated with vaccine was 6.4 weeks.

Did the vaccine shorten the duration or severity of the whoop?

In the vaccine-treated cases the average duration of the whoop was 4.8 weeks; in the non-vaccinated cases 4.4 weeks. Even in the vaccinated cases treated in the first or second week, and occasionally before the whoop developed, the

shortening of the duration of the disease would appear to be negligible. In several cases exposed to infection and seen early in the stage of incubation, vaccine treatment appeared to have no appreciable value as a prophylactic measure. It appeared to us that the vaccine which we used when given weekly, or bi-weekly, entirely failed to influence the duration or the severity of the disease either favourably or unfavourably.

The administration of vaccines to children presents difficulties. The injections were painful and upset the children considerably, especially the larger doses, so that they lost confidence in us. Unless whooping-cough vaccine can be shown to be of more therapeutic value than it has been in our hands, we consider that the distress to the child, and the risk of losing his confidence, does not justify its use.

We lack experience in vaccine therapy and fully realize that the wrong organism, intervals between injections, and dosage may have been used in this investigation. We are of the opinion that the following points in treatment aid in the shortening of the disease and the prevention of complications.

Hygienic.—Fresh air seemed an all-important point, and undoubtedly those children allowed to run about outside with the usual precautions against exposure did much better than those confined to the house. Even those with a moderate degree of bronchitis benefited greatly with this treatment. Where there is insomnia and exhaustion, consequent on the greater severity and frequency of the whoops at night, this can be alleviated by getting the child to rest and sleep during the day.

Dietetic.—Anorexia and vomiting being constant symptoms, wasting was a constant sequel; it was often found necessary to vary the diet frequently, children taking and retaining cow's milk or some of the proprietary foods best during the acute stage. The all-important point seemed to be to prevent this wasting and to keep the child in as good physical condition as possible. The feeds were given in small amounts and at frequent intervals, and when possible immediately following on a paroxysm of coughing and vomiting.

Medicinal.—We found cod-liver oil and malt a most useful remedy. Children on this treatment actually seemed to put on weight, and during the stage of recovery from the disease a preparation of iron was added to the cod-liver oil with great benefit. To cases of bronchitis with numerous moist sounds in the chest the following mixture could be given with great benefit to a child aged 1 year, and in suitable doses to older children, every four hours:

Tincture of belladonna	mlj
Potassium bromide	gr. ij
Glycerin	mx
Water	to 5i

All our cases, both vaccinated and non-vaccinated, were given cod-liver oil and malt in suitable doses, with a liniment for the chest.

Our thanks are due to Miss Marian A. Lawson, of the Royal Free Hospital, for her very valuable assistance in administering the vaccines.

AN ARTERIO-VEINUS ANEURYSM TREATED BY LIGATION OF THE LEFT SUBCLAVIAN ARTERY.

BY

CHARLES NOON, F.R.C.S.

ASSISTANT SURGEON, NORFOLK AND NORWICH HOSPITAL.

LIGATION of the first part of the left subclavian artery is so rarely done that I think the following case may be worthy of record.

History.

A man, aged 24, was admitted to the Norfolk and Norwich Hospital on June 6th, 1921, complaining of swelling of the left upper extremity. He stated that while serving in France he was wounded in the region of the left clavicle on May 17th, 1917. After receiving treatment in various hospitals he was discharged from the army in November, 1917, on account of pain and weakness of the left arm. At the time of his discharge from the army the arm was not swollen, but at the end of 1918 he began to notice gradual increase in size of the whole of the left upper extremity, and a pulsating swelling appeared in the region of the left clavicle. The size of the arm continued to increase until there was very little use in it, and he had to carry it about in a sling. Dilated veins appeared on the surface of the axilla, arm, and forearm, and the skin of the left upper extremity assumed a dull livid colour. A superficial ulcer appeared on the flexor surface of the forearm in June, 1921, and rapidly increased in size.

Condition on Admission.

In regard to his general condition, the patient was a fairly healthy-looking, but somewhat pale man. His temperature was 98, pulse rate 83, respirations 20; tongue clean, teeth fair. With reference to the local condition the left supraclavicular fossa was obliterated by a well-marked pulsating swelling. Pulsation was also visible below the clavicle, but was less well marked than above it. There were numerous dilated and tortuous veins running over the left upper extremity, especially well marked in the axilla. The whole of the arm and forearm was a dull livid colour; the arm was much swollen, the circumference of the upper arm 4 inches below the acromion process measuring 17 inches. There was a superficial ulcer situated on the flexor surface of the forearm, having all the characteristics of a varicose ulcer. The movements of the thumb and fingers were normal; there was no loss of sensation in the hand. The pulsation in the region of the left clavicle was felt to be expansive and diffuse, extending above and below the bone. A well-marked bruit could be heard over the whole of the left side of the chest, especially well marked over the pulsating swelling above and below the clavicle. The left radial pulse was less easily felt than the right. Heart and lung normal.

X-ray Examination.—There was a small foreign body situated behind the centre of the left clavicle.

A diagnosis was made of arterio-venous aneurysm between the second part of the left subclavian artery and the left subclavian vein. Rest, careful bandaging, and elevation of the arm improved the condition slightly, but considerable swelling persisted in spite of these measures. The varicose ulceration of the forearm continued to increase; operative treatment was therefore decided upon.

Operation: Ligation of the First Part of the Left Subclavian Artery.

On September 25th, 1921, an anaesthetic (chloroform and ether) having been administered, the patient was placed in the dorsal position, the shoulders slightly raised, and the head turned towards the right side. An incision was then made from the centre of the anterior border of the left sterno-mastoid muscle extending downwards to a point just internal and below the left sterno-clavicular joint. A second incision was then made from this point extending outwards parallel with and half an inch below the left clavicle. A triangular flap of skin and superficial fascia was then raised, exposing the left border of the manubrium sterni and the inner two-thirds of the left clavicle; the attachments of the sterno-mastoid muscle to the clavicle were then defined. The muscular attachments to the superficial surface of the clavicle were next divided; the periosteum covering the superficial aspect of the clavicle was divided and separated from the bone; the clavicle was then divided at its centre and the inner half removed subperiosteally. The left half of the manubrium sterni was next cut away. The base of the wound now consisted of the periosteum, which covered the posterior surface of the manubrium sterni, the periosteum separated from the posterior surface of the clavicle, a layer of deep cervical fascia and muscular tissue consisting of part of the sterno-hyoid and sterno-thyroid muscles. The base of the wound was then enlarged by dissecting away the exposed periosteum; the sterno-hyoid and sterno-thyroid muscles were defined and retracted. The common carotid artery was then defined running along the inner aspect of the wound. The left innominate vein, formed by the left internal jugular and left subclavian veins, was now defined, and retracted outwards and downwards with some difficulty. The left subclavian artery could then be felt at the bottom of a deep wound surrounded by fatty tissue. About half an inch of the vessel was exposed, and it was found that compression of the vessel caused complete arrest of pulsation in the aneurysm. An aneurysm needle was then passed round the first part of the subclavian artery, and the vessel tied with No. 3 silk by a knot after the method of Ballance and Edmunds. This method consists of passing the separate strands of ligature material round the vessel, tying each in a simple knot in the same direction, and then by using the two strands on each side as one completing the square knot. A few bleeding points were ligatured and the wound closed; a small rubber drainage tube was retained in the wound for twenty-four hours. Dressings were applied, and the hand and limb carefully bandaged. The time taken to complete the operation was two and a half hours.

Post operative Treatment and Progress.

On September 26th, twenty-four hours after the operation, there was considerable respiratory distress, the respirations varying from 41 to 53 a minute; the pulse rate was 120, and the temperature was 100.5°. On September 27th the pulse rate was 140, fair volume and tension; the respirations 52, and the temperature 102°. The condition appeared to be due to an attack of acute bronchitis, probably caused by the administration of an unusually long anaesthetic. The condition gradually improved, and at the end of a week the temperature, pulse, and respiration were normal. The wound healed by first intention, and the stitches were removed on the eighth day. The radial pulse after the operation could not be felt, but the arm and forearm remained warm; and there was never any loss of sensation. No decrease in the swelling of the arm was noticed until the fifth day after the operation, when the limb began to decrease in size, so that nineteen days after the operation the upper arm had decreased 5 inches in circumference, measuring 12 inches instead of 17 inches. The varicose ulceration of the forearm began to heal rapidly, and had completely healed five weeks after the operation. Massage to the

hand and forearm was started four weeks after the operation, and eight weeks from the date of the operation the patient was discharged from the hospital, when no pulsation could be felt at the site of the aneurysm, but a slight bruit could still be heard. There was excellent power in the arm, forearm, and hand.

Remarks.

This was a case of arterio-venous aneurysm between the second part of the left subclavian artery and the left subclavian vein; the condition which demanded relief was the extreme swelling of the left upper extremity, which from the size and pain which it caused completely crippled the patient. The severe varicose ulceration of the forearm, associated with the varicose condition of the veins of the arm and forearm, made the possibility of septic thrombosis a very real danger. Alleviation of the condition seemed to be possible by one of the following procedures—namely, a reconstructive operation on the blood vessels which had for its object the closure of the abnormal communication between the artery and the vein, or ligation of the first part of the left subclavian artery as near to the arterio-venous aneurysm as possible; in either case it would be necessary to expose the artery and vein on the proximal side of the aneurysmal sac. When the first part of the subclavian artery had been exposed it was found that pressure on the artery at once stopped completely the pulsation in the aneurysm. From the condition of the parts it seemed very inadvisable to attempt a dissection to separate the artery from the vein, and to attempt to expose the abnormal communication between them. It was therefore decided to be content with ligation of the first part of the left subclavian artery. The completion of the operation was followed by recovery.

Success in performing this operation would appear to depend upon the elimination of the three complications which are likely to follow—namely, haemorrhage, shock, and sepsis. Before the introduction of the antiseptic and aseptic era this operation was practically certain to result in failure. Cases of ligation of the first part of the left subclavian artery have been successfully performed and reported by Halstead of Baltimore in 1892. Dr. John C. Da Costa twice ligatured the vessel, and both patients recovered. Nassau of Philadelphia also successfully ligatured the vessel. In 1897 Curtis, and in 1899 Allingham, also reported successful cases. There have certainly been other reported and unreported cases; still the operation is rarely required and seldom done.

Haemorrhage after the operation is to be avoided by paying every attention to an aseptic technique and by careful ligation of the vessel with the most suitable material. It is probable that a ligature tied with the ordinary knot is more likely to ulcerate than one tied after the method of Ballance and Edmunds. The ligature should be tied so that the vessel is merely compressed and the coats of the artery are not divided. It has been stated that Halstead and Darling consider an absorbable material should be used for the ligature material.

It is an interesting fact that gangrene of the upper extremity rarely follows ligation of the subclavian artery; this, of course, is accounted for by the very free anastomosis which is present; still, cases have been recorded in which gangrene has followed the operation, so that it is important to take every precaution to prevent it. For the control of gangrene after operation for aneurysm two things are under the control of the surgeon provided there is no indication for immediate operation—namely, the method of operating and the time of operation. In the former the primary consideration is to save as many of the affected vessels as possible; in the latter, to allow sufficient time for the establishment of the collateral circulation. In this case the immediate result of the operation was to increase slightly the swelling of the arm, but this began to rapidly decrease five days after the operation. The radial pulse ceased on ligaturing the artery, and had not returned three months after the operation; but the collateral circulation is well maintained, the swelling of the arm is only slight, and the patient can use the hand well.

I have to thank Sir Hamilton Ballance for his advice and help in treating this case.

THE report of the school medical officers of Tokyo states that in 1921 there were 4,273 cases of scrofula, 399 of anaemia, 939 of cardiac disease, and 1,335 children with narrow chests; the cases constituted 9 per cent. of the school children of the city. According to this report nearly all children who contract tuberculous disease before the age of 14 succumb before they reach the age of 20.

THE USE OF THE VAN DEN BERGH TEST IN THE DIFFERENTIATION OF OBSTRUCTIVE FROM OTHER TYPES OF JAUNDICE.

BY

J. W. MCNEE, M.D., D.Sc., M.R.C.P.

(From the Medical Unit, University College Hospital.)

At a recent meeting of the Association of Physicians of Great Britain and Ireland, held in Oxford, Professor Hijmans van den Bergh of Groningen gave a short account of his important work on the presence of bile pigment (bilirubin) in the blood serum under normal and pathological circumstances. In doing so he made reference to the test for bilirubin in serum and other albuminous fluids which is now prominently associated with his name. I have made use of this test in the wards and in experimental work for some months, and the results obtained have up to the present fully realized expectations. It was intended to wait until a much larger series of observations had been carried out, but since none of the work of van den Bergh has so far been published in English the writer has been asked to make some of the main facts accessible at once, leaving the fuller account for subsequent publication. It must therefore be understood that the conclusions reached in this short paper cannot be regarded as final, unless confirmed elsewhere or by future work on the subject.

The first account of the work of Hijmans van den Bergh on the presence of bile pigment in serum appeared in 1913,¹ and a full description of his observations has been collected in a monograph entitled *Die Gallenfarbstoff im Blute*, published in 1918.² More recently (June, 1921) a short summary of the main methods and facts appeared in the *Presse Médicale*.³

Confirmation of some of the chief results claimed by van den Bergh has already been given in Germany by Lepchne (1921)⁴ and Rosenthal and Holzer (1921).⁵

The clinical application of the test in the differentiation of various types of jaundice will be dealt with here alone, although this is merely a small part of the ground which has been covered by van den Bergh. The important observations which are more concerned with experimental work on diseases of the liver, and with the occurrence of latent jaundice under conditions in which icterus has not hitherto been recognized to exist, must be omitted. It is already certain, however, that future research work on hepatic disorders must be greatly influenced by the application of the knowledge made available by van den Bergh's methods.

The chief clinical value of the test is that by its use jaundice due to obstruction of the main bile ducts by carcinoma, hepatic cirrhosis, obstruction in the portal fissure, or gall stone in the common bile duct, can be clearly differentiated from jaundice of haemolytic origin or due to functional derangement of the liver cells. In this latter category are now included the various forms of haemolytic and acholuric jaundice, and also functional jaundice, such as catarrhal jaundice, toxic jaundice in infective diseases (typhoid fever, pneumonia), icterus neonatorum, etc. It is perhaps not yet generally accepted, except by those who have followed closely the work on hepatic disorders published in recent years, that all modern work strengthens more and more the view that a true haemolytic icterus, apart from the liver, does occur, and also that "catarrhal jaundice" depends on a hepatitis with functional derangement of the liver and not on an obstruction to the bile ducts. The newer methods of van den Bergh throw further light on the question from a new angle, and entirely support both the occurrence of a functional icterus apart from biliary obstruction, and of a haemolytic icterus with which the liver itself is not concerned.

The value of van den Bergh's test in the differentiation of obstructive from what may be termed functional and haemolytic jaundice is illustrated by a few chosen reports of cases given at the end of this short communication.

MECHANISM AND TECHNIQUE OF THE TEST.

Hijmans van den Bergh began his work faced with a difficulty which has confronted all who have worked chemically or experimentally on the different forms of jaundice—namely, the want of a delicate and trustworthy test for small amounts of bile pigment in an albuminous fluid such as blood serum. The tests hitherto employed, such as the Gmelin and Huppert tests, with their various modifications, have many disad-

vantages (especially in albuminous fluids), and are, besides, far from delicate for quantitative estimations.

Van den Bergh has applied for his purpose the so-called "diazo reaction," first described by Ehrlich, who found that bilirubin, when dissolved in chloroform or alcohol, gives with diazonium salts a reddish colour in neutral solutions and a bluish colour in acid solutions. Making use of this reaction to detect the presence of bilirubin in blood serum, van den Bergh and Snapper found that it gives extraordinarily delicate and certain results. They observed, for example, that every normal serum contains bilirubin in a dilution of from 1 in 400,000 to 1 in 250,000. Such a dilution in human serum is readily detected by the diazo test. They found further, after much observation, that no other substance likely to be present will give the reaction, and they have never detected any other substance in a human serum, except bilirubin, which has given a positive result. Biliverdin does not react to the test. It is to be noted also that lutein, which in certain cases (diabetes, etc.) may deeply colour human blood serum and even give the appearance of jaundice to the skin, does not give the reaction.

Technique of the Test.

For the test, as ordinarily carried out, about 3 c.cm. of serum may be required, although less will suffice after some practice has been obtained. The blood is taken from a vein in the usual way into a dry test tube, allowed to clot, and the separated serum is then removed by a pipette. It is best to begin to practise the test on a case of fairly intense icterus.

Apparatus and Reagents Required.

1. A few test tubes of ordinary size.
2. Freshly prepared Ehrlich's diazo reagent. This consists of two solutions, each of which keeps well, but the mixture of the two must only be made immediately prior to the test. The two solutions are made up in the following proportions:

A. Sulphanilic acid	1 c.cm.
Concentrated HCl	15 c.cm.
Distilled water...	1,000 c.cm.
B. Sodium nitrite	0.5 gram
Distilled water...	100 c.cm.

The diazo reagent consists of a mixture of these two solutions in the proportion of 25 c.cm. of solution A to 0.75 c.cm. of solution B.

3. A graduated 1 c.cm. pipette.
4. Absolute alcohol (96 per cent.).
5. A centrifuge and centrifuge tubes.

The test is then carried out as follows: To 1 c.cm. of the serum, in a small test tube, van den Bergh adds 0.25 c.cm. of freshly prepared diazo reagent. (Lepchne, and the writer, have found that better results are frequently obtained by adding 1 c.cm. of the reagent.) One of three events may now occur:

1. *An Immediate (Direct) Reaction.*—This begins instantly and is maximal in ten to thirty seconds. The colour reaction obtained is a bluish-violet, of intensity depending on the amount of bilirubin present.

2. *A Delayed Reaction.*—This begins only after one to fifteen minutes, or even longer, and consists in the development of a reddish coloration, which gradually deepens and becomes more violet. (It will be seen later that this reaction is not made use of further, being replaced by the so-called indirect reaction or test—vide infra.)

3. *A Bi-phasic Reaction.*—In this a slight reddish colour appears immediately (ten to thirty seconds), which after a minute or much longer time is seen to deepen gradually and become more violet.

Interpretation.

If the reaction is immediate or direct an obstructive jaundice is indicated.

If a direct or immediate reaction is not obtained proceed as follows: To 1 c.cm. of serum add 2 c.cm. of 96 per cent. alcohol. The mixture is made in a centrifuge tube, which is then centrifuged until all the albuminous precipitate has sunk to the bottom to leave a clear yellowish supernatant fluid. To 1 c.cm. of this supernatant fluid add 0.5 c.cm. of alcohol and 0.25 c.cm. of Ehrlich's diazo reagent. (The reason for the addition of 0.5 c.cm. of alcohol is to get a proper dilution for the quantitative test, referred to below, and may be omitted where that test is not being carried out.) A violet-red colour is then obtained if bilirubin be present, which is of maximal intensity almost at once.

Where no direct reaction has been given, but a perfect indirect reaction after alcohol precipitation, then the jaundice

can be inferred to be either haemolytic in origin or dependent on some functional derangement of the liver cells without obstruction.

It should be mentioned that all serums which give a direct reaction will give in addition an indirect reaction, but the converse is not, of course, true.

By those two simple tests, therefore, a distinction can be drawn between icterus due to obstruction of the main bile ducts from gall stones, tumours, hepatic cirrhosis, etc., and an icterus of haemolytic, infective, or functional origin.

What is the mechanism of the test, and how is it that the bilirubin present in the serum in obstructive jaundice reacts to the diazo reagent quite differently from the bilirubin in haemolytic, catarrhal, and other forms of jaundice?

It appears to depend on the fact that the bilirubin differs molecularly in the two conditions, and, without going deeply into theoretical considerations here, van den Bergh suggests that in the case of bilirubin giving the indirect test only, the pigment has been in some way bound to albuminoid substances in the serum, and the union is only broken down by time or by alcoholic precipitation. The reader must be referred to the original papers for further consideration of this point.

Taking this short explanation for granted, the rationale of the bi-phasic reaction becomes intelligible. It would appear to depend on the presence of both types of bilirubin, in different proportions, in the same serum. If the first variety predominates, the reaction might be described as bi-phasic direct and the other as bi-phasic indirect. The occurrence of the bi-phasic reaction is fortunately not very common, but until much further experience with the test has been gained it is best for the moment to draw no absolute conclusion in a case giving such a result. The writer is finding such cases of great interest at present, and it is already evident that in, for example, cardiac valvular disease with failure, back pressure, and hepatic enlargement, the icterus which sometimes occurs may be at first functional, and later obstructive in type as the hepatic enlargement increases, the bilirubin showing a gradual transition through a bi-phasic stage with the test.

Application of the Test for the Quantitative Estimation of Bile in Serum.

Although the simple test as described above will probably be the first to be commonly used clinically, it is an obvious advantage to be able to estimate the increase or decrease of bile pigment in the blood serum, especially in cases of obstructive jaundice. This may have importance, for example, in cases of suspected carcinoma of the liver, or in the recognition of the exit of a gall stone from the common bile duct. It is, of course, well known that the icteric tint of the skin changes comparatively slowly. It has also an importance in the study of various forms of "latent icterus," such as in cases of pernicious anaemia. These questions will be dealt with in a later communication.

The so-called indirect test of van den Bergh, which, as has been stated, is given by all forms of icterus whether obstructive or non-obstructive, lends itself easily to a quantitative estimation of bilirubin by a colorimetric method. For full details of the method the original papers should be consulted, but the main principles may be briefly given here. At first van den Bergh made use of chemically pure bilirubin to prepare a solution for comparison, but he was able soon to replace this with an artificial standard solution giving a colour suitable for comparison. This solution, moreover, is made up in a strength which can give a definite reading in "units" of bilirubin. The artificial solution consists of iron sulphocyanide dissolved in ether, in a concentration of 1 in 32,000 normal. This solution is of a colour which corresponds exactly with that of azo-bilirubin (as produced in the "indirect test") of 1 in 200,000, the quantity found to be the average amount in the serum of a healthy individual. An indirect reaction giving a colour exactly corresponding to this standard is taken as indicative of "1 unit" of bilirubin.

The Solution of Sulphocyanide.

The standard solution of iron sulphocyanide is prepared as follows:

Dissolve 0.1508 gram of ammonium iron-alum in 50 c.cm. concentrated HCl and add water to 250 c.cm. This gives a dilution of 1 in 8,000 normal, which will keep for about six months.

To 3 c.cm. of this solution add an equal volume of 20 per cent. potassium sulphocyanide and 12 c.cm. of ether. Shake well, and when all the reddish colour has passed into the ether

transfer the ether carefully, either into a colorimeter, or other comparative tube. This solution is in a concentration of 1 in 32,000 normal, and must be prepared freshly each day a test (or tests) is made.

I have made use of the simple Anteuirith-Funk colorimeter for the quantitative estimation, but any form of colorimeter is, of course, applicable. For rough clinical use dilution of the fluid obtained in the indirect test may be made in test tubes of equal calibre, and reasonably accurate comparative results obtained. It should be pointed out that even with the complete technique of van den Bergh the results are of an accuracy which is adequate for clinical purposes only. There are various fallacies which prevent a completely accurate estimation of the whole of the bilirubin present in any serum. One of the chief of these depends on the fact that some bile pigment is always carried down in the albuminous precipitate when alcohol is added. The amount, however, is always small, and is greater in cases of obstructive than of non-obstructive icterus.

REPORT OF CASES.

Case 1.

Female. History of three attacks of jaundice, with vomiting and epigastric pain, within a period of a few months. Stools clay-coloured. X-ray examination showed two shadows at the level of the twelfth rib, to the right of the middle line, but deeply back in the body. There was doubt as to what these shadows were—biliary calculi, renal calculi, or calcified glands. On the clinical features of the case a diagnosis of gall stone blocking the common bile duct was made.

On applying the van den Bergh test the following result was obtained:

Direct test ... Negative.
Indirect test ... Positive (3 units of bilirubin).

Exploratory laparotomy was performed; the gall bladder and bile ducts were normal, and patent throughout. The liver was not enlarged, but icteric in colour. The diagnosis was changed to catarrhal jaundice, and the patient made a straightforward recovery.

Case 2.

Female. This patient, a nurse in a fever hospital, had been previously admitted for jaundice, which was said to have followed a febrile illness of some weeks' duration. Typhoid was at first suspected, but the Vidal reactions for the enteric group of fevers were negative. The jaundice passed off, but the patient was re-admitted for a second attack, accompanied by pain in the right hypochondrium. The stools were light coloured. A diagnosis of gall stones was made.

The result of the van den Bergh test was as follows:

Direct test ... Negative.
Indirect test ... Positive (4½ units of bilirubin).

The abdomen was opened, but the gall bladder and bile ducts were found to be normal. The patient quickly recovered, and the jaundice passed off.

Case 3.

Female. History of several attacks of severe pain in the right hypochondrium. Never jaundiced until one week before admission. Jaundice of moderate degree. Cholecystitis was the diagnosis regarded as probable.

The van den Bergh test gave the following result:

Direct test ... Positive.
Indirect test ... 4 units of bilirubin.

At operation the gall bladder was found to be much contracted and embedded in dense adhesions passing along the portal fissure. One large stone was removed from the gall bladder, but examination of the common bile duct was almost impossible owing to the dense adhesions. A leak unfortunately occurred from the septic gall bladder, and fatal peritonitis followed. At the necropsy the gall bladder was found to be greatly contracted and strictured. The common bile duct was embedded in dense adhesions, but no stones were found.

Case 4.

Male. History of jaundice of three weeks' duration; loss of weight; stools light coloured. Nothing could be made out by palpation of the abdomen.

The van den Bergh test resulted as follows:

Direct test ... Positive.
Indirect test ... 12 units of bilirubin.

At operation a carcinoma of the head of the pancreas was found, obstructing the ampulla of Vater.

The writer wishes to thank members of the staff of University College Hospital and Lewisham General Hospital for access to cases. The work forms part of an investigation carried out under the auspices of the Medical Research Council.

AN ETHEREAL EXTRACT OF STRAWBERRIES
FOR THE TREATMENT OF SPRUE.ALDO CASTELLANI, C.M.G., M.D., M.R.C.P.,
BY
K. C. BROWNING, M.A., F.I.C.

[A Preliminary Note.]

THE favourable influence of a strawberry diet on sprue has been known for some time. As it is difficult and expensive to get strawberries except in the short season, and, moreover, strawberries forcibly grown out of season do not seem to have the same beneficial effect, we sought a method by which the active principle or principles could be extracted and stored.

Continuous extraction apparatus for extracting a solution with a light solvent. A. Condenser is fitted at D. The solvent is placed in K. The solution to be extracted is corked in A, which is then closed by a cork. Small Raschig rings can be put in A to help the extraction.

account of a fat-soluble factor deficiency. After a number of preliminary experiments, the following procedure was adopted:

Fresh strawberries were crushed with about 5 per cent. of their weight of absolute alcohol and filtered in a powerful filter press. The juice was then extracted for days in a continuous ether-extracting apparatus. The ethereal extract was immediately concentrated in a vacuum over phosphorus pentoxide, a small quantity of either starch or lactose being added. The residue was dried as completely as possible in a vacuum over phosphorus pentoxide, as this appears to ensure greater stability. The apparatus used is illustrated, and is very convenient. To get the most rapid extraction by thoroughly mixing the solvent with the solution being extracted, a number of Raschig rings are placed in A. These consist of rings whose diameter is equal to their length. They can be made of any suitable material—for example, by cutting 5/16 in. aluminium tubing, 22 gauge, or from glasses. Prolonged experience has shown their value in extractions (cf. Buyer and Co., *Journal of Soc. Chem. Ind.*, 1919, 752a).

The extract we have prepared (mixed with a little starch) is of a dark red colour, has a granular-sealy appearance, is somewhat soft, and has a very powerful fragrant smell of fresh strawberries. A minute quantity of it has been kept in an amber tube for the last ten months (since last June), and apparently has not lost any of its characteristics, being of the same colour, and its fragrant smell being just as strong. The experimental investigation of this extract is difficult, as sprue cannot be reproduced in the lower animals; we have to rely therefore only on clinical observations but owing to

The experiments of Dr. S. S. Zilva (*Biochemical Journal*, 1920, pp. 494-501) and those of Osborne and Mendel (*Biochemical Journal*, 1920) on the extraction of antiscorbutic and antineuritic principles from cabbages and carrots suggested the method which was adopted. Dr. Zilva showed that it was possible to extract, by means of alcohol, the fat-soluble factor from cabbages and carrots, and that the alcoholic extract also contained the antineuritic and, to a smaller extent, the antiscorbutic factors. He also showed that if the alcoholic extract of cabbages and carrots were further extracted with ether, the ether contained a substance which promoted recovery and renewed growth in rats deficient in weight on

On January 10th, 1921, the right kidney was exposed by the usual oblique lumbar incision; it was found to be enlarged, and some difficulty was experienced in delivering the lower pole; when the kidney was eventually brought up to the surface, this difficulty was found to be due to an aberrant renal vessel which was passing directly outwards and behind the ureter to the extreme lower pole of the kidney. This was divided and ligatured; the pelvis was found to be dilated to a considerable extent above the level of the divided artery; the ureter below was traced downwards for some distance, and appeared to be of normal calibre. The pelvis of the kidney was opened and a catheter passed down into the ureter without difficulty; there was no evidence of valve or constriction at the junction of the ureter with the pelvis of the kidney. The opening in the pelvis was sutured, the kidney dropped back, and the wound closed with a small drainage tube in the upper angle. There was no leakage of urine. The patient made a good recovery, and has been quite free from his symptoms since.

I first saw this patient in August, 1920, and was unable to come to a diagnosis. He had consulted several medical men from time to time, and was referred to me again in January, 1921, by a pensions board for an explanation of his symptoms, as the question had arisen as to whether his condition could be attributed to military service.

I never saw the patient during an attack of pain, which is perhaps the reason why no enlargement of the kidney was made out on examination; I was induced to explore the kidney because it was obvious that the patient

HYDRONEPHROSIS DUE TO ABERRANT RENAL ARTERY.

E. C. BEVERS, M.B., B.Ch.Oxon., F.R.C.S. Eng. and Edin.,
BY
HONORARY SURGEON, RADCLIFFE INFIRMARY, OXFORD, AND
LITCHFIELD LECTURER IN SURGERY, OXFORD UNIVERSITY.

SOME doubt has recently been expressed as to how far abnormal renal vessels are responsible for the hydronephrosis with which they are associated. In the following case the hydronephrosis appeared to be directly due to the aberrant vessel, and the symptoms disappeared after the operation, which consisted simply of division of the abnormal vessel.

E. H., a well-developed, healthy young man of 22, stated that in the summer of 1918 he experienced pain under the right costal margin, and in the mid-axillary line; this pain went through to his back, but never down the flank or into his leg. The attacks of pain were infrequent to begin with and of short duration; later they became more frequent and more severe, generally coming on in the early morning, lasting about two hours, and passing off after he had walked about a little.

At the commencement this pain came on about once a fortnight; these attacks have gradually increased in frequency, and at the present date (January 5th, 1921) they are appearing three times a week.

In the early part of 1920 there was one bad attack which lasted twelve hours and kept him in bed for a few days. When the pain is severe there is biliary vomiting, but blood has never been brought up; there was no frequency of micturition during the attacks, but he states that there was frequency and the passage of an increased quantity of urine after the attacks.

Between the attacks he feels quite well, his appetite is good, and he has lost no weight, and no history of jaundice could be obtained. He had suffered from malaria while on foreign service in 1916 and 1917.

He has given this history in detail as the patient was very clear as to the nature of the attacks, their increasing frequency and severity, the relief obtained by moving about, and his perfect health in between the attacks.

The right kidney was palpable, not unduly mobile, and at the time did not appear to be enlarged, but was distinctly tender. The left kidney was not palpable, and nothing else of an abnormal nature could be detected in his abdomen. A radiograph of both kidneys was taken, but was negative. His urine was normal, and cystoscopic examination showed both ureteric orifices to be normal and acting well.

Operation.

On January 10th, 1921, the right kidney was exposed by the usual oblique lumbar incision; it was found to be enlarged, and some difficulty was experienced in delivering the lower pole; when the kidney was eventually brought up to the surface, this difficulty was found to be due to an aberrant renal vessel which was passing directly outwards and behind the ureter to the extreme lower pole of the kidney. This was divided and ligatured; the pelvis was found to be dilated to a considerable extent above the level of the divided artery; the ureter below was traced downwards for some distance, and appeared to be of normal calibre. The pelvis of the kidney was opened and a catheter passed down into the ureter without difficulty; there was no evidence of valve or constriction at the junction of the ureter with the pelvis of the kidney. The opening in the pelvis was sutured, the kidney dropped back, and the wound closed with a small drainage tube in the upper angle. There was no leakage of urine. The patient made a good recovery, and has been quite free from his symptoms since.

I first saw this patient in August, 1920, and was unable to come to a diagnosis. He had consulted several medical men from time to time, and was referred to me again in January, 1921, by a pensions board for an explanation of his symptoms, as the question had arisen as to whether his condition could be attributed to military service.

I never saw the patient during an attack of pain, which is perhaps the reason why no enlargement of the kidney was made out on examination; I was induced to explore the kidney because it was obvious that the patient

was suffering very severe discomfort, which rendered him unfit to follow an occupation, and because from time to time one comes across cases of unilateral renal pain in which no very obvious explanation can be found for the patient's symptoms. An operation in such case may, as here, reveal the cause of the pain. In another similar case I found at operation a cyst of the left renal cortex (the size of a pigeon's egg); it was not palpable before operation, and its removal cured the patient's symptoms. In other cases where no cause for the pain can be found at the operation, simple decapsulation of the kidneys will often effect a cure; so that exploration of the kidney concerned is always justifiable in cases of continued renal pain without obvious cause. That the artery was the cause of the hydronephrosis in this case seems a reasonable assumption, as the dilatation extended to the point where the vessel crossed behind the ureter, and ceased below that point, and as the patient's symptoms have disappeared after division of the vessel.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CONGENITAL ABSENCE OF DELTOID MUSCLE.

WHILE examining a man, aged 23, for life assurance I discovered the fact that he had no right deltoid muscle; he was otherwise of normal muscular development. He knew of no muscular peculiarity in either of his parents or his brothers. He had served four years in the army during the late war, and was well able to carry out his duties. It was interesting to note how he managed to raise his arm in the absence of the deltoid muscle. He could abduct his arm quite normally until it reached the height of his shoulder; it then became tremulous. He gave a slight jerk, which dislocated the head of the humerus backwards until it rested apparently against the muscles attached to the spine of the scapula. With this firm support the pectoral muscles seemed to be able to raise the arm to its full extent upwards.

When standing at ease the head of the humerus showed up well under a very thin covering of skin and subcutaneous tissues, the capsule of the joint was thin and loose, and the head of the bone could be moved freely to and fro in its socket. The arm hung down by the side with the elbow slightly bent and pointing outwards; the hand was rotated inwards with the radial side resting against the leg.

The biceps muscle was specially well developed, and he asserted that his right arm was stronger than his left. He had never felt inconvenience from the absence of the deltoid.

London, E.C.

E. J. TRELL.

A CASE OF HEAD INJURY.

THE following case may be of interest to record as showing the great degree to which the brain may be damaged with little sign of external injury:

On Sunday, April 2nd, about 9.40 p.m., a girl, apparently about 20 years of age, was brought unconscious to my house, with the history that from a bus travelling at a moderate speed she had jumped off facing the wrong way and fallen on her back.

I could find no external sign of injury except a very slight degree of bogging above the occiput. There was no bleeding from mouth, nose, or ears. The pupils were equal, neither contracted nor dilated, and the corneal reflex was present, though not brisk. She could not be roused by shouting.

During the first ten to fifteen minutes Cheyne-Stokes breathing was marked, and towards the end of that time she began to vomit and move her head and limbs in a restless manner; just before the vomiting her pupils became nearly fully dilated. After this her breathing became quiet and regular except when interrupted by vomiting or retching. Later on movements became more purposeful—for example, she tried to remove her gloves by biting the tips of the fingers and pulling out her hands. At 10.30 p.m., when she left the house, her pupils were, as at first, neither contracted nor dilated. She could still not be roused to answer questions, nor did she make any sound herself.

As the identity of the girl could not be discovered she was sent in an ambulance to the local cottage hospital. The matron reported afterwards that the girl was restless and retched several times without the unconsciousness becoming any less deep. Her condition remained the same until

1.50 a.m., when she suddenly stopped breathing and died about two minutes later, without becoming cyanosed.

Post-mortem examination showed a small abrasion above the right elbow as the only external sign of injury. The scalp above the occiput, over an area about two inches square, and the right temporal muscle were infiltrated with blood clot. There was subdural haemorrhage over the whole upper surface of the left cerebral hemisphere, and disintegration and haemorrhage at both frontal poles, particularly the left. There was, lastly, an extradural haemorrhage of about three drachms in the right middle fossa. No sign of fracture could be found. No examination of the rest of the body was made.

The diametrical transmission of the injuring force was most marked, as the infiltration of the scalp was greater on the right side than on the left. The mechanics of the meningeal haemorrhage is more difficult to understand. I can only suggest that, since a considerable degree of deformation of the skull is possible in a young subject (the girl's age was 17), the meningeal artery might be damaged by momentary stretching. It is true that an elastic artery might be expected to recover from stress better than the more rigid skull, but it is hard to suggest any more plausible theory. In any case the disparity between the clinical symptoms and the internal damage must remain the most interesting feature of the case.

Grays, Essex.

L. G. JACON, M.B., B.Ch. Cantab.

PAIN IN THIGH: CEREBRAL AND PULMONARY HAEMORRHAGE: DEATH.

IN THE BRITISH MEDICAL JOURNAL of April 22nd, 1922 (p. 635), Dr. Wilfred Harris states that intraspinal haemorrhage in the region of the *canda equina* may, after clotting, cause obscure pain in the lower extremities which may lead the medical attendant astray.

A man, aged 30, of previous good health, suffered from intense pain in his left thigh. I could find nothing locally to account for his pain, and prescribed a liniment, which he said gave him relief. After a few days' suffering he returned to work.

A little later he complained of severe pain under the right mamma. His temperature was raised; as I heard a rub I strapped his chest, with good results. I saw no reason to doubt my diagnosis of pleurisy, but was puzzled by oozing of blood from his gums. Scurvy and a tropical disease were discounted. A few days later his pleurisy had cleared up, but his gums were now bleeding freely. Suddenly he passed into a state of unconsciousness and died in two hours.

Post-mortem I found a recent haemorrhage in the internal capsule and a haemorrhage into the right lower lobe of the lung anteriorly. The cause of the haemorrhages I could not decide on.

The pain in his thigh was a mystery till I read Dr. Wilfred Harris's article. Possibly he had had an intraspinal haemorrhage.

Had I examined his nervous system carefully when I first saw him I might have detected some signs and symptoms, but pains in the legs are fairly common, and when a pain is relieved by a simple liniment one does not think of rare diseases.

Kilnhurst, near Rotherham.

CHARLES J. HILL AITKEN, M.D.

SIMPLE TEST FOR SUGAR.

A drop of urine containing sugar evaporated on a microscope slide over the flame of a spirit lamp leaves a "tacky" glistening film of syrup. Further heating turns this film a rich golden colour. Full heating converts the deposit into burnt sugar or caramel. Urine containing 14 grains to the ounce, according to fermentation test, gave the reaction after dilution with five times its volume of water. The test was demonstrated at a meeting of the North Lancashire and South Westmorland Branch at Kendal last October.

JOHN LIVINGSTON, M.D. Dnch., F.R.C.S. Ed.

Barrow-in-Furness.

THE Graduate School of Medicine of the University of Pennsylvania, in association with the Medical Society of the State of Pennsylvania, is undertaking the establishment, at a number of points throughout the state, of post-graduate medical extension groups, whereby medical practitioners situated far from the hospitals of the larger cities will be able to keep in touch with recent developments in clinical work and discoveries in medical science.

Reports of Societies.

CHOREA GRAVIDARUM.

A MEETING of the Midland Obstetrical and Gynaecological Society was held at the King Edward VII Hospital, Cardiff, on April 6th, when the President, Professor EWEN MACLEAN, read a short communication on three cases of chorea gravidarum. The cases described conformed to the type of ordinary, or Sydenham's, chorea as distinguished from the far more grave Huntington's chorea. As regards etiology of chorea gravidarum it was generally held that in these cases we were dealing with a true chorea and not a manifestation of toxæmia. This view was supported by the frequency of a rheumatic history, evidence of endocarditis in a large proportion of cases, and the detailed resemblance to Sydenham's chorea, while in the majority of cases other evidences of toxæmia, such as albuminuria and severe vomiting, were absent. The incidence of the disease was commonest in primigravidae, though it might recur in subsequent pregnancies, and the onset was more frequent in the earlier months of pregnancy. Milder types tended to recover under treatment, rarely, if ever, developed mental symptoms, and only exceptionally miscarried. The severe types were frequently associated with abortion, and were held to be responsible for a maternal mortality as high as 20 to 30 percent. As regards treatment, mild cases responded to rest and dieting associated with arsenic, bromide, chloral, etc., as the symptoms indicated. In severe cases the prognosis, immediate and remote, was bad; treatment as a rule was ineffective, and the induction of abortion or premature labour before the signs of exhaustion became established appeared to be the best line of treatment to adopt.

Case 1.—A 3-gravida, aged 26, had a history of rheumatism and of two previous miscarriages. She was six months pregnant when seen, and had been having severe choreic convulsions for two months. With rest, screening, and occasional doses of chloral and bromide, her condition rapidly cleared up. Normal delivery took place at term, and there were no more choreic fits. The urine was normal throughout.

Case 2.—A primigravida, aged 24, was two months pregnant. She had chorea eighteen months and acute rheumatism twelve months previously, and chorea for the past two weeks, the condition becoming worse in spite of treatment. Pregnancy was terminated, and rapid improvement and cure followed. The urine was normal.

Case 3.—A primigravida, aged 22, was seven months pregnant. She had a history of chorea on and off for four years. Under treatment, with complete rest and silence, potassium bromide and arsenic, the choreic symptoms improved steadily, and she was awaiting the onset of labour. The urine was normal throughout.

It was noteworthy that all three cases gave a history of antecedent rheumatism or chorea; none showed albuminuria or other evidence of toxæmia; none showed any tendency to spontaneous abortion; and the one severe case in which abortion was induced showed almost immediate relief of symptoms.

Mr. E. TENISON COLLINS showed the following specimens: (1) Uterus and both appendages removed from a nullipara, aged 25, for menorrhagia. The uterus was irregularly enlarged, some of the nodules being very soft, and were thought to be possibly sarcomatous. The pathological report stated that only fibrous tissue was present. (2) A large ovarian tumour removed from a woman of 55. The tumour on section showed some cystic spaces and considerable areas of what appeared to be fat. No pathological report was yet available. (3) A bone stilette, which, when passed by a woman to procure abortion, had disappeared inside her. It was located by x-rays and found free in the pelvis without any evidence of infection or inflammation. (4) A large stone removed by vaginal cystotomy. In spite of the presence of cystitis, the wound had healed uninterruptedly.

Dr. PURSLOW showed a specimen of foetus compressus. The specimen shown had been expelled early in labour, and was followed in due course by a full-term female child. There was a single placenta, the condition being one of homonymous twins.

Dr. RAYNER reported a case of rupture of the uterus during natural delivery. The patient, aged 25, had had two previous normal pregnancies. The pelvis was normal. She had been in labour two hours, when one very strong pain expelled the child, which was dead, with a loop of cord wound tightly round its neck. The placenta was expelled, and the uterus retracted firmly. When left the woman was comfortable,

with a pulse rate of 115. An hour later she collapsed, the pulse rate rose to 150, with signs of internal hæmorrhage, and free fluid in the flanks, but the uterus was still well retracted. There was free blood in the peritoneal cavity, and a 3-in. tear in the uterus, the right uterine artery being lacerated. These lesions were dealt with by suture and ligature, and she made a good recovery. Dr. Rayner suggested that the cause of rupture in a healthy uterus, as this was, might be violent movements of the child after the birth of the head, and thought that some of those cases diagnosed as post-partum shock might in reality be minor degrees of ruptured uterus.

Dr. STRACHAN showed a specimen of anencephaly in which the placenta was attached to the base of the skull by a thick, firm amniotic band, and a small placenta succenturiata was actually adherent to the skull. There was evidence of other amniotic adhesions in the stunted growth of the left hand. Dr. Strachan pointed out the significance of these obvious amniotic adhesions in view of the theory that amniotic adhesions during the early weeks of gestation cramped the growth of the cerebrum, with the ultimate result that the cranial bones did not develop and anencephaly resulted.

Dr. STRACHAN also showed a specimen demonstrating placental apoplexy. The specimen was the uterus and placenta from a woman admitted in the last stages of eclampsia, who died undelivered. There was extensive retroplacental hæmorrhage, with obvious bleeding into the placental tissue, and a microscope slide showed hæmorrhagic infiltration of the uterine muscle. Retroplacental hæmorrhage might cause death by actual excessive loss of blood, or lead to congestion in the separated portion of placenta, and thus to intraplacental hæmorrhage. From this necrotic area of placenta toxæmia leading on to eclampsia might develop.

Dr. B. K. TENISON COLLINS showed a specimen of fibromyoma complicating pregnancy. There was a history of two and a half months' amenorrhoea, but the uterus was felt as a hard mobile mass, considerably larger than the period of amenorrhoea, filling the pelvis and rising into the abdomen. Subtotal hysterectomy was performed. The uterus was irregularly enlarged by multiple fibroids and contained a two and a half months' foetus.

HOSPITAL LIGHTING.

A DISCUSSION on hospital lighting took place at a combined meeting of the Illuminating Engineering Society with the Sections of Surgery and Ophthalmology of the Royal Society of Medicine on April 27th. Sir JOHN HERBERT PARSONS, who presided, said that of all the instruments which the surgeon or physician had to use light was the most important and subtle, and its proper quality and direction made all the difference to the observations.

The discussion was opened by Mr. JOHN DANCER, an illuminating engineer, who laid it down as axiomatic that quiet and pleasant ward lighting could best be obtained by combining a system of general with a system of local illumination. The general illumination might be quite small, but it must be well diffused and without glare, while the local lighting should provide each patient with three foot-candles on his book, should be under the patient's or his nurse's control, and should not be in the centre of the bed-head, but 15 in. to the patient's left to avoid heat on the head and gloss on the book. It should also illuminate the chart, and not to offend anyone else, should be recessed in a dark-green shade. For a night light nothing was more soothing than a quiet, indirect illumination. There should be no gloss above the dado (which should be dark) and the ceilings and friezes should be white. The operating room presented other problems. Here the surgeon was often worried by shadow or glare, and sometimes by uneven or ill-directed light. The ideal light for operating would be in the open under a clouded sky, and that condition should be the aim in artificial lighting. The room should be designed to secure the greatest possible angular expanse of glass without admitting direct sunlight. The ceilings and wall surfaces should be white, smooth, and washable, and a pale-green dado would afford some relief to the eye. Artificial illumination must be abundant—not less than 25 foot-candles—and so thoroughly diffused as to eliminate conflicting shadows. There should be no exposed light sources within the ordinary field of vision, and the colour of the light should be as white as possible. The speaker's own idea was to have the operating theatre quite clear of fittings, and to light it

room entirely from outside the window by clusters of powerful lamps enclosed in waterproof reflectors; nothing was better than the white flanneo arcs which were used before the war. Provision must be made for emergency lighting, but risks of failure were now so greatly reduced that to clutter the ground with alternative fittings, each one a dust-trap, was not justifiable. It was sufficient precaution to place one half of the lamps on an entirely separate circuit, and to have in another room an accumulator large enough to maintain some powerful hand lamps for several hours. No doubt artificial daylight would be very useful when a suitable lamp of sufficient intensity was forthcoming, but such daylight lamps as were available were too feeble and clumsy for surgical use. Mr. Darch, in closing, put in a word for the dispenser, who frequently had to work under very bad lighting conditions; he suggested that a plain white screen would save him from eyestrain when using graduated glass measures.

In the subsequent discussion Mr. C. C. CHORCH said that in certain operations, particularly gynaecological ones, it was sometimes an advantage to have two horizontal beams coming one from each side of the sitting operator. He liked the idea of lighting the theatre from outside altogether, but he questioned whether it might not mean additional risk of breakdown. He mentioned that Professor Carrel, of New York, had been working in theatres the walls and floors of which were entirely black, which, he believed, obviated eyestrain. Black was a funereal colour, and probably a dark olive-green would serve the same purpose. Floors should certainly be dark, and walls up to eye-level lighter, and above eye-level perhaps white.

Mr. W. T. HOLMES SPIER pointed out that if the light was generally diffused exact definition was not obtainable. The surgeon needed the shadows to guide him. All glare should be excluded, as well as all reflections—he was speaking of ophthalmic work—except those from the eye under examination. In 1893, he was staying with Professor Snellen, of Utrecht, who had then adopted the principle of operating in an otherwise darkened room, with a window whose separate panes could be uncovered at will, so that he had a beam of light exactly under his control, and Snellen claimed that much acuter vision was possible under those conditions.

A number of euglaers also took part in the discussion. One of them urged the advantages of artificial daylight, or at least of an illuminant of constant colour, so as to permit of the proper examination of rashes and other conditions in which colour was important. One or two microscopists also took part, and discussed the best light for the microscope, which it was agreed was light of shorter wave-lengths, although to go too far to the violet end of the spectrum was not consistent with comfortable vision. Mr. C. RAPHAEL criticized indirect lighting, which he considered cheerless and also very expensive. The original installation was more costly than that for direct lighting, and the running costs were very much greater. The "scintytic" lamp and other models for shadowless lighting were demonstrated at the close of the meeting.

A MEETING of the West Kent Medico-Chirurgical Society was held in the Miller General Hospital, Greenwich, on April 21st, when the President, Dr. C. T. T. COMBER, O.B.E., occupied the chair. Dr. MAURICE DAVIDSON showed two cases of encephalitis lethargica in young girls, one of whom was mild and had recovered with the exception of pain in the neck; the other was more severe and showed seventh nerve palsy after eighteen months. Dr. JAMESON showed a young girl with transposition of the thoracic and abdominal viscera. Mr. C. J. S. THOMPSON, M.B.E. (Curator of the Wellcome Historical Museum), delivered a lecture entitled "Parturition chairs, their history and use," which he illustrated by lantern slides. The first was used at Luxor; stools were mentioned in the book of Exodus of the Bible. The chairs usually had a horseshoe-shaped piece cut out of the bottom; later, hand-grips were added, then foot-rests. Leather upholstery of the seat and back came into use. In Cyprus the chair was made of a solid block of wood with two cavities. Chairs were in use in Germany in the seventeenth century. Parturition chairs were still in use in Turkey, Egypt, and Japan. Smellie mentioned their use in this country, and there was also a reference in a play by Ben Jonson, but the lecturer had never been able to discover one in England.

THE next congress of thalasso-therapy, which was to have been held at Venice next October, has been postponed till the spring of 1923, when it will receive the patronage of the King of Italy.

Rebichus.

NERVE EXHAUSTION.

SIR MAURICE CRAIG has written a small volume on *Nerve Exhaustion*,¹ designed for the use of the medical practitioner. He has aimed to keep the text as free from technical terms as possible in order that it may be easily understood by those medical men who either have not had the time or have lacked the opportunity to study psychology. Particular stress is laid on the problem of the prevention of nerve exhaustion, and with this end in view much attention is given to the condition of "hypersensitivity," which the author finds constitutes the invariable basis of nervous collapse. This condition manifests itself in both the physical and psychical spheres, and may be inherent, or acquired by an undisciplined or ill-regulated use of the nervous system. If the signs of this hypersensitivity are recognized, either in the child or adult, it is suggested that the graver and more intractable symptoms which follow may be avoided by submitting the patient to a life suitable to his capacities.

A chapter on causation is followed by one on symptomatology. The manifold symptoms of nervous exhaustion are included under the headings of sensation, disorders of perception, including hallucinations, attention, emotion, association of ideas, habit, memory, movement and action, will power and action, impulse, suicide and homicide, jealousy, irritability and suggestibility, conflict and dissociation, including fugues, adaption and regression, anxiety, fatigue and headache, and various bodily symptoms. A survey of this section indicates that the term "nervous exhaustion" is here used in a very general sense; it is made to include a wide range of morbid manifestations, and Sir Maurice Craig evidently does not intend to use the term as synonymous with neurasthenia. A special chapter is devoted to sleeplessness, and the practitioner will find in it a number of useful hints with regard to the treatment of this troublesome symptom. The question as to the use of drugs is fully discussed, but we miss any reference to the treatment of the anxiety state which is often responsible for persistent insomnia.

The section on diagnosis is somewhat scanty, and might usefully be expanded in a future edition. Especially would it seem necessary to remind the practitioner of the possibility of overlooking an early case of general paralysis, as the symptoms in this disorder often closely resemble those of neurasthenia. The author has included in his chapter on treatment some important observations on the lunacy law and the question of certification. Owing to his great experience his views on these questions carry much weight and deserve close consideration. He points out that the treatment of the more severe forms of functional nerve disorder is greatly hampered by legal considerations, and urges a considerable modification of the law as it now stands in order that a number of cases may be treated away from home without the necessity for certification. It is probable that the modifications in the existing law which Sir Maurice Craig advocates will be before long carried into effect, and if not to the extent that he would wish, at any rate sufficiently to remove some of the difficulties which at present prevent the carrying out of adequate treatment in a number of cases.

PROBLEMS OF LEUKAEMIA.

PROFESSOR ELLERMANN'S book on the *Leucosis of Fowls and Leucemia Problems*² is of interest because it describes in detail the author's important researches on these diseases of fowls, and discusses the bearing these investigations have upon the leukaemic diseases of man. The word "leucosis" has been proposed because in the fowl there are many different disease complexes due to abnormal production of leucocytes, in some of which no changes are to be found in the peripheral blood. To avoid the use of such expressions as "aleukaemic-leukaemia" or "pseudo-leukaemia" the name "leucosis" is employed to designate all diseases characterized by an excessive production of leucocytes. In the fowl there are three distinct varieties of leucosis—the lymphatic, the myelotic, and the intravascular lymphoid leucosis. In the lymphatic leucosis there is no anaemia and the blood picture is normal, but *post mortem* it is found that the liver is much enlarged and studded

¹ *Nerve Exhaustion*. By Maurice Craig, C.B.E., M.D., Cantab., F.R.C.P., Lond. London: J. and A. Churchill, 1922. (Demy 8vo, pp. 143. 6s. net.)
² *The Leucosis of Fowls and Leucemia Problems*. By Wilhelm Ellermann, M.D. London: Gyldehall, 11, Hanover Square, 1922. (Demy 8vo, pp. 105; 3 coloured plates, 8 figures. 2s. 5s. net.)

with white points, and the spleen and kidney enlarged; microscopically hyperplasia of all lymphatic tissue is seen; this disease is essentially a lymphoblastic hyperplasia. In myeloid leucosis, a rapidly fatal infection of fowls, the spleen is relatively more enlarged than the liver, and the bone marrow is greyish-red; microscopically the liver, kidney, and spleen are seen to be infiltrated with myelocytes, and the peripheral blood may contain up to 600,000 leucocytes per c.mm., the majority being myelocytes. The intravascular lymphoid leucosis corresponds more closely to the lymphatic leukaemia of man, and the lymphoid leucocytes in the circulating blood are of a mild degree of anaemia.

It was Ellermann and Bang who first, by injecting an emulsion of the organs of an infected fowl into a normal fowl, demonstrated that the leucosis of fowls is communicable. They were able to propagate the infection from generation to generation. In 1908 they concluded, therefore, that the infective agent is an ultramicroscopic filtrable virus; they found that it was possible to transmit the disease in sequence by the injection of a Berkefeld filtrate of a saline emulsion of liver, spleen, and kidney of infected animals.

The diseases of fowls characterized by excessive production of leucocytes show many points of resemblance to the lymphatic and splenomedullary leukaemias of man, and suggest the possibility that human leukaemias may also be due to some hitherto undiscovered infective agent. In support of this there has already accumulated a certain amount of evidence; leukaemia often appears to be endemic, and occasionally cases have occurred in hospitals and other institutions which have suggested communication of an infection. But such a point can only be decided by further researches and the accumulation of clinical evidence. Unquestionably Professor Ellermann and his co-workers have greatly enlarged our knowledge of these obscure blood diseases and opened up many new lines of inquiry. This book will provide interesting and stimulating reading to all who have made a special study of the various human blood diseases.

GYNAECOLOGICAL TEXTBOOKS.

THE early appearance of the second edition of *Diseases of Women*,³ by Ten Teachers, shows that this book has realized the well-deserved popularity which we anticipated. It is stated to have undergone a careful revision, and the authors are to be congratulated on achieving this and at the same time reducing the size of the volume by a few pages. In part this reduction has been accomplished by condensation of the letterpress, in part by leaving out a number of the illustrations. The process does not seem to have affected the book adversely in any measure, the omitted pictures being not wholly essential to the elucidation of the text. The difficulty of obtaining uniformity in outlook where so many authors are engaged in a collective effort can still be observed, but in our opinion this is less noticeable than it was in the first edition, and, in any case, it is not a shortcoming of real moment. It is unnecessary to notice this volume at any length, as it is a comparatively short time since we had the pleasure of reviewing the first edition, and the changes, so far as we have been able to detect them, are mainly in matters of detail. The book remains an admirably clear, comprehensive, and, without, simple exposition of gynaecology as it is practised and taught in this country. The student who is reasonably familiar with its contents need have no fear of any examiner in the subject, while the practitioner who has this book in his library will find in it all the information that he is likely to require in connexion with his gynaecological cases. We congratulate the authors, and the publishers also, on the success of a valuable book.

The appearance of the second edition of Professor W. E. FOTHERGILL's *Manual of Diseases of Women*⁴ shows that this work has found its public. As in the first edition, the main points of interest lie in the strictly pathological classification adopted in the description of gynaecological

disorders, and in the strongly individual note that runs through all the teaching. Professor Fothergill was one of the pioneers in the introduction of a pathological classification into descriptive gynaecological textbooks, and he must be gratified to see how many of the best textbooks have been modelled upon the same system. At the same time we feel that, when pursued as rigidly as is the case in this manual, the method seems to involve a good deal of repetition, and that some modification of it would make for simplification from the point of view of the student. For the gynaecologist, however, this strict classification has very considerable advantages, and there is no doubt that this feature is, as we have said, one of the main grounds on which the book makes its appeal. Any defects in the method adopted by Professor Fothergill should stimulate other teachers to strive after a better pathological classification.

The fact that many gynaecologists will disagree with the author upon small points makes the book all the more worth reading. It stimulates the reader to challenge views which he may have adopted long since without due examination as to their correctness or otherwise, and may have continued to hold without feeling the need for revising them. Some of Professor Fothergill's refreshingly direct expressions of opinion have this tonic effect. In his preface the author says: "The douche-can and the plug are passing away at last. The pessary is also going; for vaginal surgery has advanced until it is now possible to guarantee a cure in practically every case of genital prolapse without opening the abdomen." All this is correct, but it is not the profound statement which it might appear at first sight to be, nor is it true to the extent which Professor Fothergill would seem to believe or hope. The pessary must always remain for those who, for one reason or other, decline operative treatment, and the can and the plug, however much abused, have also their legitimate and useful sphere (as subsequently described in the author's pages), even if it be only one case out of a hundred in which they are commonly prescribed. Professor Fothergill states that the rôle of radiology in pelvic surgery has hardly reached the textbook stage, and that organo-therapy remains in the journalistic phase but promises to take its place in the books of the future. While not challenging these statements we should have thought that experience in both these domains was now becoming crystallized to an extent which would justify some remarks for the instruction of the student and the practitioner. We shall look forward to subjects in Professor Fothergill's next edition.

TWO YEARBOOKS OF TREATMENT.

THE *Medical Annual*⁵ has now reached its fortieth volume, and there is no sign of decrease in value or interest. Probably no periodical is more widely read by the English family doctor than this, and there is certainly nothing else which in such compact form can keep him abreast of new developments in medicine, whether internal, surgical, or specialized. There is a sanity in this yearly review that soberly appraises innovations. The practitioner may learn from this volume that there are drawbacks to some greatly vaunted remedy, or that some method which he unhesitatingly has regarded as quackery deserves further consideration. Among the newer subjects discussed mention may be made of that of endocrinology by Dr. Langdon Brown, an admirable summary; of neurological surgery (under several headings) by Mrs. Ramsay Hunt; of non-specific protein therapy, in which Dr. Herbert French briefly describes the methods of performing cutaneous tests for food- and pollen-idiosyncrasies, and the desensitization of sufferers by inoculation. There are noteworthy articles, too, on mental diseases by Dr. Stanford Read, and on psychological medicine by Dr. J. A. Hadfield. In a short but instructive survey Mr. Thurstan Holland describes the aid now obtainable from x rays in diagnosis, a field in which immense progress has been made since the war. Mr. Hey Groves has written a clear and well-illustrated account of advances in orthopaedic surgery, and a great deal of new work on syphilis is collected and reviewed by Colonel Harrison. We note with satisfaction that the publishers have been able to reduce the price of the book from 25s. to 20s., without interfering with the quality of the paper, the printing, or the illustrations.

³ *Diseases of Women*. By Ten Teachers. Edited by Comyns Berkeley, H. Russell Andrews, and J. S. Fairbairn. Second edition. London: Edward Arnold and Co. 1922. (Med. 8vo. pp. 611, with 215 figures; 8 coloured plates. 30s. net.)

⁴ *Manual of Diseases of Women*. By W. E. Fothergill, M.A., B.Sc., M.D., Professor of Obstetrics and Gynaecology, Victoria University, Manchester. Edinburgh: W. Green and Son, Ltd. 1922. (Demy 8vo. pp. xix + 433; 149 figures. 10s. net.)

⁵ *The Medical Annual*, 1922. Bristol: John Wright and Sons. 1522. (Demy 8vo, pp. lxxvii + 752; illustrated. 20s. net.)

Dr. CHREINISSE, who is responsible for the section of the *Presse Médicale* devoted to therapeutic progress, presents in his yearbook of treatment for 1921 a summary of new suggestions which have appeared during the past year. The scope of the book is much more strictly limited to therapeutic details than is the case in the *Medical Annual*. The French yearbook is a summary of information about drugs and their doses; no mention is made of surgical measures of therapeutics. The arrangement is alphabetical according to diseases. For the most part the novelties in treatment are described in uncritical quotations from the authors' statements, but the references to the original articles are invariably given. A study of the American and English accounts of the treatment of diabetes by fasting has stimulated the editor to one of his most interesting digressions. He states that the method is not new, that it had its origin in France many years ago, and that it has never been more than a palliative which may diminish the gravity of the disease but does not cure it. If, in succeeding volumes, the editor continues to review his subjects critically after this fashion he will add immensely to the real value of the publication. This is only the second year of issue, and such works must necessarily start from small beginnings.

MEDICAL OPHTHALMOLOGY.

MANY years have passed since the publication of the last edition of a book with a somewhat similar title by Gowers and Marcus Gunn, and although that work is a classic and can still be read with advantage by practitioners of medicine and by ophthalmic surgeons, yet there was need for a more up-to-date exposition of the subject; we therefore offer a cordial welcome to the work of POSTER MOORE,⁷ which has recently been published. In his preface the author states that his aim has been "to give a concise account of the pathological conditions of the eyes and their connexions, which, for the most part, are of interest in general medical diseases." Most excellently has he succeeded in his aim; the book is packed with information, and references are given in footnotes on each page, which will be found to be of the greatest value to the reader. For the most part the subject of treatment is excluded.

The changes are described, as a rule, under the headings of the separate diseases, but in Chapter I will be found a very important group of eye signs and symptoms. These are described without special reference to the diseases with which they are connected; for instance, Gordon Holmes's and Lister's work on the cortical representation of vision, papilloedema, nystagmus, retinal haemorrhage in general, bi-nasal hemianopia, indirect paralysis of the cranial nerves, and haemorrhage into the optic nerve sheath. Especially good are the chapters on arterio-sclerosis, the anaemias, and renal retinitis, fields in which the author has done a great deal of valuable work; but the whole book is excellent, and as an instance of the same way in which it is written we would commend the remarks on the question of small errors of refraction as a canso for epilepsy and migraine.

In our opinion this book is one of the most useful to the physician and to the ophthalmic surgeon alike that has appeared in this country in recent years. The printing and paper are good, the illustrations admirably illustrate the text, there is a very full index, both of subjects and of authors, and the typographical errors are very few.

THE HYGIENE OF THE SCHOOL CHILD.

WE are familiar with books on the hygiene of the child written by members of our own profession, but we have received recently a volume written by a layman, LEWIS M. TERMAN, Associate Professor of Education of the Leland Stanford Junior University,⁸ and designed for use in normal schools, colleges, and teachers' reading circles. It is a well-balanced statement of the conditions of health, and the effects, mental and physical, likely to follow departures from those conditions. With an essentially practical outlook upon health,

the author begins by a statistical statement of the values of humanity and the lost values of the dead, which is a striking commentary on the economy of efficient public health services. He computes, or cites computations of, the values of the individual in dollars, and these values translated into pounds sterling at pre-war rates of exchange read as follows: It is computed that the now-born child has an average money value of at least £20. The value increases to £200 by five years, to £800 by twenty years, and drops again to £500 by fifty years. The minimum average loss to society from each postponable death has been elaborately calculated at £300. It is estimated that of the 1,500,000 deaths in the United States each year at least 42 per cent. (600,000) are postponable. The annual loss from this cause is therefore £200,000,000. The loss from preventable illness is calculated at £400,000,000 per annum, or four times the total expenditure on public education. Much of this loss is due to sheer ignorance.

"The daring researches of a few score bacteriologists are more than offset by the thousands of people who still use liverwort for jaundice because of the fancied resemblance of its leaf to the human liver; by tens of thousands who treat infectious diseases by suggestion; by the millions who spend hard-earned money for patented consumption cures. Popular notions regarding personal hygiene are little better than a seething welter of ignorance and superstition, not all of which is confined to those who are confessedly uneducated."

If this had been written by a physician the layman would have remarked that the physician was exalting his office.

The book is divided into chapters, dealing with the physical basis of education; the general laws of growth and factors of influence; physiological differences between children and adults; physiological age; disorders of growth; malnutrition; tuberculosis; ventilation; teeth; nose and throat; hearing; vision; headache in school children; mental hygiene; speech defects; sleep; and some of the evils of school life. Nearly all are very well written and show an understanding of the practical application of medicine to school medical inspection. To each chapter is appended a list of references to original papers or books recommended for consultation. In the last chapter there are some well-considered cautionary remarks on the effects of school life.

"There is reason to believe that the intellectual apathy of older children and adults is sometimes due to school over-dosage, or to other kinds of educational malpractice. It has often been charged that the school has a depressing effect upon a child's spontaneity; that it mechanizes his mental processes, and destroys the individualistic elements in his personality."

Attempts have been made to measure this depressing effect by observations of spontaneously controlled drawings. Fortunately the exuberance of vitality is so marked a characteristic of childhood and youth that many escape without observable injury. Nor are the evils which do exist beyond remedy. There is no reason why the school should not be as healthful in its influence upon both body and mind as the most perfectly ordered home. Until it approximates to this ideal, the campaign for school reform should continue. The book is well written, and will be of value to English readers as well as to those for whom it was designed.

SEROLOGY.

IN a volume of less than three hundred pages on the ground-work of serology ASCOLI states clearly the chief facts of that department of science, and in the translation into German which Dr. R. S. HOFFMANN⁹ has made the reader's time is saved by the liberal use of marginal headings. After tracing the history of serology in an initial chapter, theories of immunity are discussed in detail. An account of the chief antitoxic and antibacterial serums is next given, and this is followed by a description of the best known antibodies. Complement-fixation has a chapter to itself, as also has the sero-diagnosis of syphilis. The meiostagmin reaction for the diagnosis of malignant disease is described, as well as Alderhalden's procedure for the same purpose. In a final chapter the main facts of anaphylaxis are enumerated.

This book is an excellent compendium of current Continental teaching on the subject of immunity, and may be recommended to those requiring a work of that kind. The authors, however, have but little to say about the Schick test, in connexion with diphtheria outbreaks; furthermore, recent work

on the serological types of pneumococcus and meningococcus is ignored, as also is Droyer's technique for applying the agglutination test. Doubtless reference to these matters, and also to the recent work of Dale on anaphylaxis, will be made in future editions of a work that claims to cover the ground-work of serological science.

NOTES ON BOOKS.

THE third edition of the late Professor L. DONCASTER's *Heredity in the Light of Recent Research*¹⁰ was not completely revised at the time of this brilliant worker's lamented death; the additions rendered desirable by the labours of Professor Morgan and his school with regard to hereditary transmission, and intended to be summarized in an appendix, have not been made. Since the second edition in 1912 the progress of knowledge has rendered necessary some modification and additions to the chapters on the inheritance of acquired characters, and on the inheritance of sex. An interesting discussion showing the fallacies attending some of the experiments made in connexion with the subject leads to the conclusion that, though the hypothesis of the inheritance must be regarded as non-proven, recent evidence makes a dogmatic denial of its possibility inadvisable. The widely held belief in maternal impressions is shown to have no firmer foundation than accidental coincidence. The chapter devoted to heredity in man deals in an interesting and clear manner with the transmitted liability to tuberculosis, insanity, and other conditions. This small book contains much to satisfy the medical man's desire for knowledge on this important and advancing subject.

Many are the methods that have been devised to popularize a study of hygiene and to simplify for the general public the laws of health. That of Sir ROBERT FIRTH, by means of a small fourteen-page folder, is excellent, and in *Health in a Few Words*¹¹ he has succeeded in setting forth in simple language that which ought to be known by everyone who desires to keep in good health. The various sections of the leaflet deal with the dwelling, air, water, food, personal hygiene, infantile mortality, infection, and disinfection. That upon personal hygiene is particularly clear and concise. It hardly seems possible to have put into 350 words so much valuable information as this section contains. Public health officers ought to find the judicious distribution of this leaflet of great assistance to them.

The *Medical Record* of New York, which has been appearing as a weekly periodical for the last fifty-six years, has ceased to exist as a separate publication; it has been combined with the *New York Medical Journal*, which appears semi-monthly. For the first thirty-eight years the *Medical Record* was edited by Dr. George F. Sbrady; he was succeeded by his assistant, Dr. Thomas L. Stedman. The periodical was published throughout the whole of its career by the firm of William Wood and Company, which has been engaged in medical publication for 118 years.

¹⁰ *Heredity in the Light of Recent Research*. By the late L. Doncaster, Sc.D., F.R.S., Derby Professor of Zoology, Liverpool University. Third edition. The Cambridge Manuals of Science and Literature, No. 2. Cambridge, 1921. (Pp. 163; 13 figures, 4s.)

¹¹ *Health in a Few Words*. By R. H. Firth, D.P.H., F.R.C.S. London: John Bale, Sons, and Danielsson, Ltd. 1921. (3 × 4½, pp. 14. 2d.; post free, 3d.)

THE OPIUM COMMISSION OF THE LEAGUE OF NATIONS.

[FROM A CORRESPONDENT AT GENEVA.]

THE Advisory Commission of the League of Nations with regard to the traffic in opium and dangerous drugs began its second session in Geneva on April 19th. It was expected that the business might be finished in three days, but owing to difficulties arising from the recrudescence of opium cultivation in China the sittings continued for more than a week. The Chairman was Sir Malcolm Delevingne, of the Home Office, who was the British representative. The representative of France, M. Bourgeois, occupied the vice-chair, and the other countries represented were Germany, the Netherlands, Portugal, India, China, Japan, and Siam. This was the first appearance of Germany at a council table of the League of Nations, and the representative of that country, Dr. Anselmino, evidently felt himself in a position of difficulty. Germany was invited to sit on the Opium Commission chiefly on account of that country's interest in the manufacture of drugs, but Germany is not yet a member of the League of Nations, and therefore its representative abstained from voting, and took only a slight part in the discussion. In addition to the

accredited representatives from the nine countries there were three assessors—namely, Sir John Jordan, lately British Minister Plenipotentiary in Peking, Mrs. Hamilton Wrigley (United States), and M. Brenier (France).

More than two days were spent in a discussion on the Chinese problem. At the first session of the Commission last year the Chinese Government undertook to appoint commissioners who should tour the provinces and report upon any recrudescence of opium cultivation. When the Chinese representative on this occasion, Mr. Chao-Hsin Chu, produced the promised reports it was found that they were of a very untrustworthy character. In many cases the investigation had been made at a time of year when, at any rate in a rapid tour over the vast areas involved, it was not possible to detect a poppy crop. The poppy flowers in March and April; yet, in quite a Gilbertian manner, the investigations appeared to have taken place mostly in October and November. The optimistic statements of these Chinese commissioners were at variance with more authentic information from unbiased sources, and Mr. Chu admitted that much of his information was unsatisfactory. He persistently refused, however, every suggestion of interference, even in the most helpful spirit, by the League of Nations, contending that the opium question was not a China question but an international question, and that no special action must be taken with regard to China which was not taken with regard to other countries. To arrive at some compromise which would not hurt the susceptibilities of China, and yet should restrain the undoubted recrudescence of poppy cultivation in that disturbed country during the last five years, taxed all the wit of the Commission, and the situation was made more piquant because the Japanese representative, who admitted that there had been an extensive importation of drugs into his country beyond all legitimate requirements, professed himself most anxious that the League should undertake investigations into the measures by which the Japanese Government is now combating the illicit traffic.

The principal piece of work which the Commission has done is to set up a system of importation certificates, under which, if a dealer in dangerous drugs in one country desires to import such drugs from another country, he must obtain from his own Government a certificate of approval for each consignment, together with the statement that, in the case of raw opium, it is required for legitimate purposes, and, in the case of morphine, heroin, cocaine, or medicinal opium, that it is required solely for medicinal or scientific purposes. The use of the words "legitimate" with regard to opium and of "medicinal or scientific" with regard to prepared drugs is a compromise arrived at chiefly to meet the position of India. The Government of the exporting country will not issue its licence until the certificate from the Government of the importing country has been received. If this recommendation is adopted by the Council of the League this month it will come into force for Europe and America next September, and for the Far East and Australasia next January. The Commission itself is only an advisory body.

One sitting of the Commission was devoted to exploring what might be considered the maximum legitimate consumption of dangerous drugs. A report prepared by Sir George Buchanan and Dr. Carrière, of Switzerland, was presented, which described certain investigations in a few civilized countries, relatively small in population, and in which there was little or no material abuse of the drugs, or, if there was such abuse, means existed for determining with reasonable accuracy the extent of the proper medicinal use. The countries originally selected for this purpose were Belgium, Switzerland, the Scandinavian countries, and Australia and New Zealand. No useful figures are yet to hand with regard to the two last, and as for Belgium, in view of new legislation and administrative measures there, it is considered that more useful information may be obtained at a somewhat later date. In Switzerland Dr. Carrière has sought the co-operation of doctors, pharmacists, and the hospitals, and has arrived at figures representing within a margin of 20 per cent. what he believes to be the total legitimate consumption, and similar inquiries have been carried out in Denmark and in Sweden by Dr. Madsen. The year to which the following figures (see table, p. 725) relate is, in the case of Switzerland, 1921, in Sweden, 1920, and in Denmark, 1917.

The considerable consumption of heroin in Switzerland appears to have no counterpart in Scandinavian countries: in Sweden the amount of heroin consumed was only two kilograms. It will be seen also that the consumption of cocaine

	Total Quantity in kilograms.	Per Head of Population (grams).
SWITZERLAND.		
Opium and preparations and extracts	704	0.17
Morphine	234	0.058
Heroin	174	0.043
Cocaine	229	0.057
SWEDEN.		
Opium	1,603	0.27
Morphine	120	0.02
Cocaine	150	0.025
DENMARK.		
Opium	467	0.15
Morphine	58	0.033
Cocaine	48	0.015

is more than twice as great per head of population in Switzerland as in Sweden, and more than three times as great as in Denmark. These three countries can be properly compared because all are small countries, all were neutral in the war, and all have a relatively high standard of health; the annual mortality rate in Switzerland is 14 per 1000, in Sweden 13.29, and in Denmark 13.4.

Dr. F. Norman White, who occupies an official position on the International Health Committee of the League, was present at this sitting of the Opium Commission, and amplified Dr. Carriero's report. He said that the investigators who had carried out the task in Switzerland were impressed by the great difficulty of undertaking any similar inquiry in a larger country. The difficult question was to decide as to the limits of legitimate use. If it was said that all opium prescribed by a doctor was legitimate, it must be remembered that, at any rate in some countries, these drugs might be abused by the medical profession. Moreover, even among practitioners in countries where there was a high standard of medical qualification, great diversity of opinion existed as to the use of these drugs. Some doctors used them too much, other perhaps not enough. One of the members of the Commission asked to what extent Dr. White thought that the results arrived at for European countries might be safely applied to oriental countries like India, where racial characteristics, habits of life, and incidence of disease were all different. Dr. White replied that in western countries it might be assumed that the use of a drug was legitimate if it was prescribed by a doctor, but in such a country as India it was necessary to define, not merely legitimate use, but also the doctor. He had known native practitioners in India who used opium very skilfully in the treatment of disease, but according to western standards their use of the drug would be regarded as illegitimate. He agreed that there was much greater tolerance for narcotic drugs amongst the Indian native population than amongst Europeans. The representative of India on the Commission, Mr. Campbell, stated that the average annual consumption of opium in all forms among the population of 240,000,000 of British India was between 26 and 27 grains a head. If cocaine were taken as equivalent to morphine, and both morphine and cocaine as equivalent to ten times the quantity of opium, the consumption in Denmark would represent about 10½ grains of opium a head, or about 40 per cent. of the consumption in India.

Discussion took place on the wisdom of encouraging the use of synthetic drugs which, while possessing the same medicinal value as morphine or cocaine, were less likely to form the drug habit. Dr. White believed that the new synthetic drugs led to nothing corresponding to the cocaine habit. There were instances of perversity, of course, but these needed no special legislation any more than the fact that now and again an alcoholic subject became maniacal on can-do-Cologne was a reason for special legislation against that spirit. He regarded cocaine, from the habit-forming point of view, as not one-hundredth part as dangerous as cocaine; it did not give rise to those so-called pleasurable sensations which were the root of the mischief. The German representative said that in his country research was being directed to the replacement of habit-forming drugs by others, approximately equal in medicinal value, which were not injurious. It was understood that the Health Commission of the League of Nations would get in touch with the German Government on this matter. Dr. White demurred to a suggestion from Mrs. Hamilton Wright that legislation should be introduced to prevent or limit the medical use of drugs. He did not think that medical initiative should be bound in

that way. There were certain cases in which he, were he a practising physician, would be very sorry not to have opium at his command, and he believed that many doctors did not use it enough. He was pressed by some members of the Commission to suggest a figure for consumption per head of population which might represent the utmost limit of legitimate use, so that if it were exceeded in any country suspicion would be aroused. In reply he pointed out the difficulty of expressing the potency of one drug in terms of another, and also the fact that a relatively high figure for a given country—as in the present case of Switzerland compared with Denmark—might simply mean that the statistics had been collected more carefully. A figure which should serve as a danger signal could only be arrived at as the result of an inquiry extending over several years and concerned with a number of countries.

It was reported by Britain, America, Germany, Holland, and Japan that information could and would be obtained in those countries as to the manufacture and sale of cocaine and the purposes for which the drug was produced, and the Secretariat of the League was instructed to stimulate such inquiries and correlate the results.

SIR THOMAS BROWNE:

THE STORY OF HIS SKULL, HIS WIG, AND HIS COFFIN PLATE.

BY

REV. CANON F. J. MEYRICK,
ST. PETER MANCROFT VICARAGE, NORWICH.

A PATHETIC irony seems to follow the great author of the *Religio Medici*, *Ūn Burial*, and *Vulgar Errors*, even beyond the grave.

"To be knav'd out of our graves, to have our sculls made drinking bowls and our bones turned into pipes . . . are tragical abominations escaped by burning burials."

The writer of these words suffered at least a part of a "tragical abomination," for his skull, though never "made into a drinking bowl," was almost certainly "knav'd" out of his grave. In the chancel of the great Church of St. Peter Mancroft, Norwich, is a tablet which tells us that—

"Near to the foot of this pillar lies Sir Thomas Browne Knight and Doctor in Physick, the author of *Religio Medici* and other learned books, who practis'd Physick in ye City 46 years and died Oct 19 1682 in ye 77th year of his Age," etc., etc.

The story of the "knaving" is, and must always be, wrapped in some mystery. This much is known. In 1840 the aged incumbent, the Rev. John Bowman, was mourning the loss of his wife. A grave was being prepared for her in the chancel of the church. A local antiquary, whose "acquisitive complex" was abnormally developed even for an antiquary, took from the coffin of Sir Thomas Browne the coffin plate, which was broken when forced from the lead coffin. Though he strenuously denied the theft and declared the coffin plate was in the possession of the sexton, yet in 1893, fifty-three years later, the broken plate was found in his desk among his acquired treasures and rightly returned by his executors to the church from whence he had borrowed it.

The coffin plate, which is now restored, is carefully preserved by the church authorities as near as is convenient to its original resting place. It is in the form of an heraldic escutcheon measuring 7 in. by 6 in., and broken into two nearly equal halves. On it are engraved remarkable words, of which Sir Thomas's eldest son, Edward Browne, was the author. Edward, like his father, was a ripe scholar and a great traveller. He was the author of an extraordinarily interesting book of travels in divers parts of Europe, "printed for Benj. Tooko, at the Sign of the Ship in St. Paul's Church-yard MDCLXXXV." He had the reputation of being the best bred man of Charles II's Court, was President of the College of Physicians, and physician to St. Bartholomew's Hospital. The words read as follows:

"Hoc loculo indormiens corporis spagyrici pulvere plumbum in aurum convertit." "Sleeping in this grave, by the dust of his alchemic body he changes the lead to gold."

The acquisitive antiquary who claimed to have looked into the coffin declared that the lead of the coffin had actually decomposed and changed to carbonate which crumbled at the touch. However, as we have seen, little reliance can be set upon the witness of this man. This same antiquary

declared in 1847 that seven years before, looking into the coffin, he saw not only the skull but also the hair of Sir Thomas Browne, and he described the hair as "profuse and perfect and of a fine auburn colour."

Meanwhile, in 1845, a skull had been presented to the hospital as that of Sir Thomas Browne. Unfortunately there is no record of the gift in the hospital books. Since 1845 the skull and some hair have been preserved in the hospital museum, of late years in a silver casket, presented by the late Professor Osler, perhaps the greatest authority in his day on Sir Thomas and his writings.

Many questions have been asked about the skull. No one knows who stole it or by what means it reached a certain Dr. Lubbock, who is said to be the donor of the relic to the hospital. It has been a shadow of evidence, that the sexton stole it about Norwich, and finally sold it to Dr. Lubbock. Now the sexton in 1840, when the grave was "knave'd," was a most worthy and loyal servant of the church. His son followed him, and his grandson, a great lover of Sir Thomas, is serving the church to-day. The sexton of 1840 was a man of considerable means, for he could afford to present the church that he served with such fidelity with a beautiful oak door.

Did the antiquary, who was the only man who claimed to have seen the skull and who most certainly "borrowed" the coffin plate, also "borrow," with or without the churchwardens' consent, the skull? It looks like it. Yet in dealing with relics, it is wise to walk warily. Did the antiquary really look into the grave? The story of the thick head of hair is not very convincing. For is it possible that a man who lived to 77 and who for forty years was responsible for a great practice should have died with a head covered with profuse auburn hair? There are many possibilities. It is possible that Sir Thomas was buried in his wig. It is possible, on the other hand, that the antiquary, satisfied with the coffin plate, never looked into the coffin at all. It is even possible, though unlikely, that the faithful old sexton with dry humour palmed off another skull (in 1840 the crypts were choked with them) on to the greedy antiquary.

Clearly we must walk warily. Orthodoxy and dogma are dangerous in matters relating to relics. The great philosopher's own words (*Pseudodoxia Epidemica*, Chapter V) warn us of the danger of credulity:

"A third cause of common Errors, is the Credulity of men, that is, an easie assent to what is obtruded; or a believing at first ear, what is delivered by others. This is a weakness in the understanding, without examination assenting unto things, which from their Names and Causes do carry persuasion; whereby men often swallow falsities for truths, dubiosities for certainties, sensibilities for possibilities, and things impossible, as possibilities themselves. Which, though a weakness of the Intellect, and most discoverable in vulgar heads; yet hath it sometimes fallen upon wiser brains, and great advancers of Truth."

And this cause of error, the philosopher tells us, is supinuity or neglect of inquiry, "rather believing than going to see; or doubting with ease and gratis, than believing with difficulty and purchase."

Let us therefore "go to see." In the museum of the hospital there is the skull. At first sight, with little or no knowledge of craniology, we would say: This cannot possibly be the skull of Sir Thomas Browne—that low, receding, depressed forehead is never that behind which the *Religio Medici* was conceived.

We look elsewhere for evidence of the shape of the philosopher's head. There are, fortunately, no less than four contemporary portraits. There is one in the treasury of St. Peter Mancroft—a half-length, three-quarter face. The portrait was presented to the church by Dr. Edward Howman, who owned and occupied Sir Thomas Browne's house after the philosopher's death. A second portrait is in the Bodleian Library—also a half-length and three-quarter face, and was probably painted in 1671 or 1672, just after Sir Thomas had been knighted. A third portrait is in the Royal College of Physicians, London, and represents Sir Thomas as somewhat older than in the other two pictures.

In all three pictures, though there are differences in cast of countenance and in details of dress, you see a noble face of a man of over sixty. There is a touch of melancholy in each face, and each picture represents a man who, so far from having the straitened forehead of the fool, rejoiced in the noble, intellectual forehead of a scholar. This is what one would expect, unless one had been to the museum and seen the skull.

There is a fourth and less well known portrait. It is at Devonshire House, Piccadilly, and some years ago the Duke of Devonshire kindly allowed it to be photographed and published in Norwich. It is probably the work of Van Somer, a Dutch artist who came to England in 1605. It represents the Browne family when Thomas was a few years old. Thomas Browne, mercer of London; and Anne his wife, are with their four children, Anne, Jane, Mary, and the future Sir Thomas. Even at this early age Thomas has a high forehead, the child's eyes being actually nearer the point (if a child's chin has a point!) of the chin than the top of the forehead.

Another possibility has been suggested. Dr. Beverley, a great collector of all that concerns Sir Thomas, sends me a copy of a MS. in the British Museum. It reads as follows and throws a new possibility on the skull's authenticity:

"The late Dr. Jeffery gave notice to Sir Thomas Browne's nearest relative that his vault wanted Reparation, who sent him word it might be filled up, which when the Dr. knew, desired that he might be interr'd thereon, who shortly after Dying His corpse was deposited in the Vault and afterwards filled up with earth and over the Doctor on a stone is this Ins: Johannis Jeffery, S.T.P., etc. etc. 1720 anno aet. suae 75."

From this we learn that soon after the burial of Sir Thomas Browne in 1682 his vault was filled up with soil, and that in 1720 the grave was opened, and over the coffin of Sir Thomas Browne was laid the body of Dr. Jeffery. This John Jeffery was vicar, or, as he was then called, minister, of St. Peter Mancroft, for forty-two years, from 1678 to 1720. He was appointed Archdeacon of Norwich in 1694. Sir Thomas Browne, who lived hardly a stone's throw from this church, was for four years not only

but his greatest suggested that when in 1840 the gravediggers disturbed the "filled-up" vault of Sir Thomas they must have first come upon the skeleton of John Jeffery, and that therefore the low, depressed skull is that of the archdeacon and not the philosopher. A picture of the archdeacon disposes of this possibility. The vicar was even more noble-browed than his great parishioner!

At first sight the conclusion drawn from the skull and the portraits seems almost irresistible. For could such a skull boast a brow so nobly shaped? Yet we know that artists are necessarily idealists. Portraits were in quite early times types rather than likenesses. Even when they became likenesses, something typical remained. In Caroline days may it not have been the fashion to give eminent men the high forehead that we see in Van Dyck's Charles I in the Wallace Collection, or in his Henrietta Maria in the National Portrait Gallery?

On the whole we believe, then, the tradition is true that the antiquary knew what he was doing when he rifled the grave and "knave'd" the skull, and that the governors of the Norfolk and Norwich Hospital have been guarding the great man's skull for nearly eighty years. The unbroken tradition in the sexton's family carries great weight. The Potters for four generations have all been faithful servants of the church, and the present verger, Mr. Douro Potter, is entirely convinced that the skull which the hospital authorities are returning to the church is the skull that held the brain that gave birth to the *Religio Medici*.

If a great scholar—Dr. E. Browne—wrote the Latin inscription on the coffin plate in 1682, another great scholar—Dr. Pollock, Bishop of Norwich—has in 1922 written that which is to mark the spot in the chancel of St. Peter Mancroft where the skull will lie. It is as follows:

O caput augustum, Petro custode sepulchri
Sit tibi pax; nomen vivat in urbe; vale.

Rough tracing showing the skull with its low and depressed forehead.

British Medical Journal.

SATURDAY, MAY 6TH, 1922.

THE MEDICAL CURRICULUM.

EVERY extension of our knowledge, every additional appreciation of the influence and effect of disease, has its natural corollary in a demand for revision of the curriculum. Although a wise conservatism has been the order of the day, a time has periodically come when the demands could no longer be legitimately or even safely denied. Such a time had arrived immediately prior to the outbreak of the war, and, although postponement of their consideration was thereby rendered necessary, further investigation and discussion have only confirmed and emphasized their justice and urgency. The firstfruits of the deliberations—which were resumed so soon as the war had ended—are to be seen in the provisional Regulations recently published by the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England. The Regulations are designed to come into effect at the beginning of next year; should they do so—and this would appear to be contingent on the acceptance of the General Medical Council's recommendations by other examining bodies—they will apply to candidates who have not passed the required preliminary examination in general education before January 1st, 1923. This seems rather short notice, but we may say at once that the reforms suggested are such as almost unreservedly to command approval. In the main they are the lengthening of the curriculum, the recognition of the importance of pathology and bacteriology, which are to be the subjects of a separate examination, and the requirement of attendance at ante-natal, infant welfare, and other clinics.

The lengthening of the curriculum is attained by removing the subjects of chemistry and physics into a pre-medical curriculum, in accordance with what we believe to be a generally accepted proposition that a knowledge of these two subjects should be required from any senior pupil, at a public or secondary school, who is intending to adopt a scientific career. There are not wanting signs that such schools are both willing and anxious to provide the instruction required. By the adoption of this measure almost a complete academic year is added to the medical curriculum, for, although it is proposed that general biology shall still be retained, it appears only as an addendum to physiology, and is no longer made a subject for examination; this alteration in its position seems to be only preliminary to its disappearance as a separate subject from the curriculum of the Royal Colleges. If this be the case, we are of opinion that it would be kinder to remove it altogether than to leave it in so ambiguous a place. Biology can never be wholly eliminated from the medical curriculum, since it is required in connexion with the study of so many subjects—embryology, experimental physiology, parasitology, and bacteriology. We hold, however, that the subject is so vast that only parts of it can ever be studied by the medical student, and that these parts can be most intelligently and satisfactorily taken at a later period of the curriculum, when a knowledge of the facts and principles of human anatomy and physiology has already been acquired. Biology, in other words, should be taught in terms of comparative anatomy and physiology rather than in terms of pure science, and may profitably be left to the teachers of anatomy, physiology, pathology, and bacteriology to be supplied at the appropriate times.

The First Professional Examination is divided into two parts. The subjects of Part I are Anatomy, including histology and embryology, and Physiology, including biochemistry. The introduction of embryology, the allocation of histology to anatomy, and the separate recognition of biochemistry are all innovations in keeping with the spirit and trend of the times. The examination in embryology will be according to a schedule, the details of which are not given, although from the known practical character of the examinations at the Royal Colleges we may presume it will include the general principles of embryology and have special reference to congenital anomalies. The subjects of Part II are Pharmacology, Practical Pharmacy, and Materia Medica. Five terms, or two winters and a summer, are the periods of study prescribed in preparation for this examination, periods which differ little, if at all, from those of the older regulations and which are identical with periods required by most universities, including the University of London. We are sorry to observe that a candidate is to be allowed to pass the examination in anatomy or physiology separately provided a standard of 25 per cent. is attained at the examination in the other subject. We believe this to be a mistake in more ways than one; moreover, as a student is not allowed to proceed with the work for the final examination until he has passed the whole of Part I of the first examination, the concession appears to be of dubious value. We trust further consideration will be given to this matter before the regulations reach their final form.

The Final Examination is divided into two sections. The subjects of Section I are Pathology, including morbid anatomy, morbid histology and clinical pathology, and Bacteriology; all these subjects must be passed by a candidate at one and the same time. The subjects of Section II are Medicine, Surgery, Midwifery, and Gynaecology, and they may be taken by a candidate, as at present, separately or together. The institution of a separate examination in pathology and bacteriology is, we think, from the educational point of view, the most important change in the Regulations, and will go far to redress the balance between the clinical and scientific sides of the final examination. The curriculum for Section II of the Final Examination has been extended to include courses in diseases of children and in the care of infants, in diseases of the throat, nose and ear, in diseases of the skin, in venereal diseases, in radiology, and in mechano-therapeutics. Candidates are to be required to produce evidence that they themselves have performed *post-mortem* examinations; that they have attended ante-natal clinics, have attended five labours conducted by a teacher or member of the staff of an approved hospital, and have themselves conducted fifteen other labours. The intention of these Regulations is sufficiently obvious: it is to give a more systematic and practical training in what have been the more obscure, but what are from the point of view of prevention of disease certain of the most important, branches of medicine. Attendance at courses of lectures on medicine, surgery, and midwifery is, we notice, no longer required, but the somewhat wasteful procedure, from the point of view of time, of attendance at a vaccination station is retained, although we should imagine an adequate course of instruction could readily be arranged in the sero-therapy department of any of the larger hospitals.

The broad general purpose of the changes, it will be seen, is, while retaining the strongly practical character which has always been the feature of the Conjoint Board examinations, to take the opportunity afforded by the extension of the curriculum to strengthen the more purely scientific side, and at the same time to widen the bounds of the curriculum in conformity with the progress of knowledge. The time chosen for the changes is far from being inopportune, coinciding as it does with an

epoch in which great advances have been made in medicine, and with a time at which the large entry of medical students into the schools has made a more severe type of curriculum both possible and desirable. It will further be noted that if the pre-medical curriculum is completed at school there should be little, if any, addition to the cost to the student of his training.

A new and high standard of medical qualification has now been set by the Conjoint Board in England; it cannot but affect the attitude of other examining bodies and must eventually have a great and far-reaching influence on medical education, and through that on the profession as a whole. Not for the first time has the wise statesmanship of the Royal Colleges been exercised to the benefit of the profession, but never, we think, to greater or more salutary effect.

RENAL EFFICIENCY TESTS.

MUCH attention has been directed during the past year to the subject of renal function and the clinical tests by means of which the efficiency of the kidneys may be estimated. The subject was made the text of an extremely interesting discussion that took place at a combined meeting of the Section of Medicine, the Section of Pathology and Bacteriology, and the Section of Physiology, Pharmacology, Therapeutics, and Dietetics, held at Newcastle during the Annual Meeting of the British Medical Association last year.¹ It has also been extensively debated by physicians, pathologists, and genito-urinary surgeons at the recent meetings of the Urological Section of the Royal Society of Medicine. The conclusions arrived at as a result of these discussions should for more than one reason be of great interest to the profession.

Renal efficiency is a most important topic, and on this score alone merits the attention of physicians and surgeons alike. But that which lends even greater interest to the investigation of renal functions is the fact that it has afforded a common ground for the meeting together and exchanging of ideas between representatives of so many and such diverse branches of medical science and practice. In these days of intense specialization there is a tendency for the worker in one department of medicine to lose touch with his fellow in another department, and undoubtedly much valuable knowledge is incompletely utilized from lack of liaison between the various branches of the profession. By the organization of these discussions on renal function among physicians, physiologists, pathologists, and genito-urinary surgeons the British Medical Association and the Section of Urology of the Royal Society of Medicine have done excellent service to medicine as a whole.

One result of these meetings has been to emphasize the fact that a test of renal efficiency, if it is to be of any real value, must be capable of simple and rapid performance. The number of tests that have from time to time been suggested is already too great. What is required is a simple test, or combination of tests, which will give the necessary information without the need for employing elaborate apparatus or complicated analyses. In the present stage of knowledge a careful clinical examination of the patient, reinforced by the carrying out of a few simple tests, will furnish an estimate of the functional value of the kidneys more accurate than that to be attained by the performance of numerous and complicated laboratory analyses. The time has not yet arrived for the employment of abstruse mathematical formulae and constants. Much new knowledge will have to be gathered before the functional value and

(what is still more necessary) the functional reserve power of a kidney can be stated in figures. In the meanwhile reliance must be placed chiefly on the clinical examination, and on the results of such simple tests as the estimation of the blood urea, the determination of urea concentration as carried out by Professor Hugh Maclean, and the tests of the kidney's power to excrete dyes. Although a certain divergence of view is, not unnaturally, noticeable on this last point, the trend of recent opinion seems to support the use of the dye tests in estimating renal efficiency. Whilst it is true that we have no scientific proof that there is a parallelism between the excretion of a dye and the excretion of the products of nitrogenous metabolism, there nevertheless exists a weight of clinical experience in favour of the use of such simple procedures as the indigo-carmin and phenolsulphonphthalein tests. Of these two, the former appears to have gained the greater favour. Its popularity amongst speakers at the meeting of the Section of Urology of the Royal Society of Medicine would seem to depend not only on its simplicity but also on the accuracy of the results obtained. More especially would the indigo-carmin test appear to be of use in those cases in which it is necessary to estimate the relative value of a kidney as compared with its fellow on the opposite side. In the experience of several speakers an appreciable delay in the appearance of the dye at the ureteric orifice had been noted in cases in which the renal lesion was comparatively trivial.

Although it is difficult to sum up in a few words the conclusions arrived at as the outcome of these debates, and although it must be conceded that considerable discrepancies occurred in the experiences of some of the speakers, a very definite common factor of agreement undoubtedly existed. Emphasis was laid generally on the fact that a renal efficiency test, however valuable it may be, is only one of the means at our disposal for arriving at a conclusion as to the functional value of a kidney, and that its importance in relation to that of the clinical examination must never be overestimated. With regard to the nature of the tests to be employed an equal degree of agreement was reached. While such methods as the diastase reaction and the estimation of blood sugar and of electrical resistances had their advocates, the weight of opinion was in favour of the urea concentration test, the estimation of blood urea, and, for the comparison of one kidney with another, the intravenous injection of indigo-carmin. We understand that a special sub-committee of the Section of Urology has been appointed to examine and report on the material brought forward by those taking part in the discussion. We look forward with interest to the publication of its conclusions.

NOXIOUS DRUGS AND THE LEAGUE OF NATIONS.

WE trust that the proceedings of the Committee of the League of Nations appointed to advise on the execution of the Opium Convention, reported elsewhere in this issue (p. 724), may serve to press forward that control of the traffic in drugs of addiction which we have consistently advocated for many years past in these columns. The Committee is not invested with any executive powers, and can only advise the Council and Assembly of the League as to the extent to which the International Opium Convention, signed at the Hague ten years ago, has up to the present time been carried out, and as to the steps which should be taken to secure its universal adoption and its effective application. Our own Dangerous Drugs Act, the final form of the Regulations made thereunder, and the licensing and supervision of premises where these drugs are manufactured (only recently inaugurated), may well serve as legislative

¹ BRITISH MEDICAL JOURNAL, September 17th, 1921, p. 425. Professor Maclean's book on *Modern Methods in the Diagnosis and Treatment of Renal Disease*, reviewed in our columns of January 28th last (p. 145), may also be consulted.

and administrative models which other nationalities would do well to follow.

We have previously expressed our regret that neither among the British representatives on the Advisory Committee nor among the three technical assessors of the Committee any medical man is included. Important questions, not only of a political but also of an essentially medical nature, are, we learn from our correspondent in Geneva, confronting, and indeed perplexing, the Advisory Committee. It is no doubt disappointing and vexatious that China, which agreed to arrangements with the British Government in 1908 and 1911 for the progressive suppression of the cultivation of the opium poppy *pari passu* with the abolition of the Indo-Chinese trade, should have repudiated its obligations. At one time it was credibly reported that in nearly all the provinces of China opium production had been substantially reduced or entirely prohibited, and no Indian opium has been directly imported into China for several years past. Following the revolution in China, and especially since the weakening of the Central Government, there has been from 1918 onwards a great recrudescence of opium cultivation under the provincial governors, who have found in the revenue derived from opium sales the means to pay their troops. China, it is alleged, has now become one of the greatest, if not the greatest, of the opium-producing countries of the world. It is nevertheless not a little disquieting to learn that the reduction of the import of Indian opium into China was accompanied by a remarkable increase in the export of British-made morphine to the Far East. We are not surprised to hear that the Japanese representative at Geneva was concerned at "the extensive importation of drugs into his country beyond all legitimate requirements," and there is little doubt that large quantities of morphine find their way through Japan into China; the latter country is, we believe, still innocent so far as the production of morphine is concerned. It was not a little embarrassing that at a recent meeting of the Anti-Opium Society in London a Chinese diplomat ingenuously remarked that he had observed that the anti-opium agitation was strongest in countries in which the largest amount of morphine was produced for export.

A laudable attempt is being made, in strict accordance with the provisions of the Opium Convention, to limit the export of dangerous drugs to the amount certified by the Government of the importing country to be required for medical and legitimate purposes. The Provisional Health Committee of the League has been called to the aid of the Opium Advisory Committee with a view to determine, if possible for each country, what may be regarded as the amount of legitimate consumption of the drugs in question. The problem is one of considerable difficulty, and our correspondent shows that the figures already vouchsafed from Switzerland, Sweden, and Denmark exhibit some strange anomalies. Moreover, in the case of countries like India, it has been repeatedly pointed out that where the recognized medical men are few and far between opium does not lose its efficacy when administered by irregular practitioners to whom the peasantry resort. There may be difficulties in the way of affirming that their use of the drug is illegitimate. Moreover, it was stated that the amount of the drugs in question actually consumed per head was very much greater in India than in a country like Denmark. The India Office has recently published a pamphlet entitled *The Truth about Indian Opium*, which provides much food for thought. It shows that the area under opium cultivation in British India is still about 150,000 acres, while in the Indian States there has been some increase in the area under the poppy in recent years, the acreage in them in 1919-20 being 56,934. Opium smoking is officially condemned as "essentially a social vice," and it

is asserted that morphine, if used "for other than medical purposes, invariably takes the form of dangerous vice." The India Office nevertheless has a tender regard even for the non-medical use of raw opium as a "domestic medicine," as "the commonest and most treasured of the household remedies accessible to the people," as a panacea to "avert or lessen fatigue," as a "prophylactic against malaria," and so on. It would perhaps be unkind to inquire whether any of the 10,000 chests of raw opium annually exported by the Government of India chiefly to the Straits Settlements, French and Dutch East Indies, Hong-Kong, and Macao, are there utilized for the "social vice" of opium smoking. The Indian Government stands by the report of the Royal Commission on Opium of 1893-94, which it says "remains unchallenged," although Lord Morley when Secretary of State for India declared that it had "somehow or other failed to satisfy public opinion in this country or to ease the consciences of those who had taken the matter up." Lord Morley contrasted the views of the "official-minded" with the "philanthropists" on this much-debated question. There is also the view of the scientists to be heard, who may be disposed to inquire whether the active principle of opium differs in its pharmacological effects, physical and mental, according to whether it is inhaled, ingested, or injected. Whether the world's production of opium, morphine, heroin, and cocaine, does or does not exceed the legitimate requirements of mankind may be a matter of argument, but one can hardly open a newspaper without finding that a not inconsiderable quantity of these drugs gets into unlawful hands and is put to vile and illegitimate purposes. The early and effective enforcement of the International Opium Convention was never more needed than it is to-day.

THE LISTER INSTITUTE.

THE twenty-eighth annual report of the governing body of the Lister Institute of Preventive Medicine, presented to the annual general meeting held on Wednesday, May 3rd, affords evidence of great and continuous activity in all the departments. Dr. J. A. Arkwright, who in November, 1920, took charge of an investigation into foot and mouth disease under the auspices of a committee appointed by the Ministry of Agriculture, returned to duty as assistant bacteriologist in the Department of Bacteriology in October, 1921, and resumed his investigations on the virus of typhus fever, in conjunction with Mr. Bacot. At the request of the Director-General, Egyptian Medical Service, the services of Dr. Arkwright and Mr. Bacot were placed at the disposal of the Egyptian Government, and they went to Cairo in January. The report contains an expression of the grief of the governing body that after the investigations had been in progress only two months both Mr. Bacot and Dr. Arkwright contracted the disease. Mr. Bacot, on April 22nd, as we had regretfully to announce, succumbed to the disease, but Dr. Arkwright, though at one time gravely ill, is now, we are glad to learn, making a good recovery. Mr. Bacot had been working at the morphology of the whole group of *Rickettsia* organisms and the relation of the pathogenic to the non-pathogenic species. Before his departure for Egypt he had been investigating the entomological side of the epidemiology of typhus fever in collaboration with Dr. Atkins. It is now generally accepted that the louse is the infecting agent, and previous workers have been able to infect monkeys by crushed lice, previously fed on a typhus patient during the acute stages, and rubbing this into the infected skin, but the exact mode of infection under natural conditions has not yet been ascertained. So far as the experiments of Mr. Bacot and Dr. Atkins had gone, no evidence was obtained that the infection was produced during the act of sucking, though it was found possible to pass the virus of typhus from one monkey to another by the injection of

monkey-lice infected by feeding upon an animal known to have the disease. A great deal of the time of other workers attached to the institute has been given to the problem of accessory food factors (vitamins). Professor Korenchevsky, whose attention has been particularly directed to the part played by deficient diet in the production of rickets, has also investigated the possibility of the disease being infectious; an occasion for testing the opinion was provided by the discovery of a community of rats in which an outbreak of rickets had spontaneously occurred. In view of the fact that Morpurgo has reported the isolation of a specific micrococcus from animals, subject to such a spontaneous outbreak, the inoculation of which was followed after some weeks by typical rickets, Korenchevsky searched the tissues and organisms of the rats in the outbreak mentioned above for evidence of infection, but found none. Dr. Goldblatt (Beit Fellow) is engaged, with the assistance of Miss K. M. Soames, in studying the quantitative relation of fat-soluble A to experimental rickets. The influence of sunlight upon the development of rickets in animals upon a deficient diet is also being investigated. Inquiries made for the Committee on Accessory Food Factors appointed jointly by the Lister Institute and the Medical Research Council have been continued in Vienna, and there also the influence of light and fresh air upon the incidence and cure of rickets has been studied. As rickets displays a definite seasonal incidence, the observations have been divided into a summer-autumn period and a winter-spring period. The investigation is complicated by the fact that the amount of vitamin A present in the milk of cows varies with the season, the cow apparently merely transmitting the vitamins it obtains from fresh food. In Vienna two parallel series of observations on children are being carried out simultaneously, under precisely similar conditions, except that the diet of the cows furnishing the milk to each series varies; in the one the animals are being fed upon the ration usually given to cows confined in stables in winter; in the other as much green fodder as can be procured is added to the cow's ration, and approximate adjustment of the other constituents made. In the department for the preparation and study of antitoxic serum work on the concentration of serums has been continued, and it appears probable that concentration of the original plasma to a third or a fourth of its bulk will be the most feasible method, although higher concentrations have been obtained. The new method of preparing and tubing antivariolous vaccine carried out in the Department for the Preparation and Study of Antivariolous Vaccine has given good results. A considerable proportion of this vaccine is destined for use in tropical countries, and the new preparation is being tested by medical officers at two or three stations in the tropics. There is, the report states, an increasing volume of evidence that strains of variola vary in different parts of the world and at different times. Some degree of immunity to all is produced by vaccination, but it is thought not improbable that the best immunity is one aroused by a vaccine possessed of not too distant relationship to the strain of variola locally endemic. Special strains of antivariolous vaccines have been raised from variolous material obtained by medical officers of colonial governments, and these are being studied with the object of obtaining the best immunization of the populations.

SMALL-POX IN SINGAPORE.

At a meeting of the Malaya Branch of the British Medical Association on March 16th Dr. G. A. C. Gordon, D.P.H., submitted a memorandum on a small-pox epidemic in Singapore, which came under notice in May, 1921, and was continuing to spread. Only two cases were notified monthly in June, July, and August, but in September the notifications mounted to 18, in January this year to 39, and in February to 80. The remarkable difficulty of controlling an outbreak of variola in the circumstances which exist at Singapore is well shown in Dr. Gordon's memorandum. The population is made up of Europeans, Eurasians, Chinese, Malays, Indians, Japanese, and Siamese. In races so varied there is no

common concept of communal duty in the stamping out of infectious disease. Concealment is so general that more than 50 per cent. of known cases have been discovered not by notification but through house-to-house search by sanitary inspectors, who may discover the infected hidden under beds, or rolled in bedding, or in latrines, and so forth. When death occurs the body is usually dumped on the nearest piece of waste ground, or even on the street. Under conditions like these some of this country's routine preventive measures, such as search for and surveillance of contacts, are out of the question. Even hospital isolation can be of very limited value where so many sources of infection remain scattered throughout the population. The reader, indeed, is, by a process of exclusion, forced to the view that preventive policy should be primarily directed to rendering immune by means of vaccination every member of the population who can be persuaded to accept protection; at the same time, of course, other measures must be adopted to whatever extent is found practicable. But even as to vaccination there must be problems in Singapore of which we knew nothing in England. The capital of the Malay peninsula is situated almost on the line of the Equator, and the establishment and maintenance of a stock of reliable vaccine lymph under tropical conditions is a matter of very special difficulty. References to this trouble are not wanting in Dr. Gordon's memorandum, especially to what seems locally known as "Java lymph," concerning which it is asked whether a person successfully vaccinated with Java lymph would "be susceptible to an attack of Hong-Kong small-pox." In this connexion we may refer readers to the concluding sentences of the note on the Lister Institute published above. In addition to the possibility of various strains it should be remembered, in judging the protective value of a vaccine lymph, that a local reaction to revaccination a few years subsequent to primary vaccination is not necessarily equivalent to disappearance of protection against attack or death from small-pox. The drift away from complete immunity is gradual, and the first stage is renewal of some degree of local susceptibility to vaccination. The deaths from small-pox among 269 cases were 65, or 24 per cent., and of the 65, "21 were found dead." The Chinese, who form the largest section of the population, had had much less proportionally of the epidemic than the other races, but Singapore's Chinatown is in the southern part of the city, which had not apparently been as yet seriously invaded. The fatality rate among the Chinese was, however, 33 per cent. of the cases, whilst among Malays it was 11 per cent., and amongst Indians 19 per cent. The data, however, are as yet insufficient to allow conclusions to be based on them. We take it that Dr. Gordon is a young medical administrator who has been called on to tackle a hard problem almost at the beginning of his career. He has done wisely to discuss the matter frankly with his brethren of the British Medical Association in his part of the world, and we are sure that, as regards supply of vaccine lymph and other such requirements, all the help of the Colonial Office and of the Ministry of Health will be freely available to the Singapore Health Department. He is probably right in his expectation that a speedy termination of the Singapore epidemic is not to be expected, and the Department should, if necessary, be able to get into touch with the central authorities in time to reap the benefit of their experiences of epidemic disease in our far-flung empire.

GENERAL MEDICAL COUNCIL.

THE next session of the General Medical Council will commence at 2 p.m. on Tuesday, May 23rd, when the President, Sir Donald MacAlister, K.C.B., M.D., will take the chair and give an address. The Council will continue to sit from day to day until the termination of its business. Among the subjects to be discussed the two most important deal with medical education and examination. The first has reference to the Diploma in Public Health. The discussion of the new regulations for the Diploma in Public Health has

now reached an advanced stage, and it seems probable that the recommendations of the Public Health Committee will be adopted at this meeting and come into force at an early date. The Council is directly responsible for these regulations. Those now in force were originally adopted on June 1st, 1899; they have since been amended and amplified from time to time, particularly on December 1st, 1911, with a view to bringing the special course of instruction required of candidates for the Diploma in Public Health into harmony with the duties of the modern medical officer of health, which have changed considerably since the resolutions were originally adopted. As was pointed out in a leading article published on December 10th last (1921, vol. ii, p. 1000) it is clear that a very decided advance along the whole line of instruction and examination for the diploma in public health is contemplated. At present a candidate can obtain a diploma in public health within nine months or a year after his name first appears on the *Medical Register*; it is now proposed that at least two years must elapse. A candidate will be able to take the laboratory work required immediately after registration and present himself for the first of the two examinations for the D.P.H. as soon as he pleases thereafter; but if the new scheme is adopted he will in future not be admitted to the second examination until the end of the second year from registration. It is believed that a new graduate in medicine will be the better qualified to take up the special duties of public health administration if he has become somewhat more mature in thought and in general outlook than is usually possible for a medical student immediately after obtaining a registrable medical qualification. How such part of the two years as is not devoted to study for the diploma in public health should be spent is not specified, but no doubt it is hoped that either through hospital or private practice the young man may in most cases learn something of the proper relations of the public health official to the public and to the general practitioner. A candidate will, however, be required to spend six months in practical training under a medical officer of health, and this training will include instruction in the administration of the newer activities of public health departments—maternity and child welfare, and the school medical, venereal disease, and tuberculosis services. It is desirable to emphasize that this training is not to be clinical in nature, but administrative. Clearly the Council has not forgotten that the position and experience of the general medical practitioner as family doctor should be recognized, and that he must not be ousted from his own sphere of work. The other matter affects the general medical curriculum: it was discussed at length in our columns in January, 1921, in a series of articles on "Reform in Medical Education." The proposals arose out of an instruction given by the Council to its Education Committee in May, 1918, to make a report on the question whether any action should be taken to promote and systematize the teaching of preventive medicine in the medical schools and in clinical hospitals throughout the country. The committee consulted the schools, and reported in May, 1920, that the questions raised by them would involve the revision of the whole curriculum in medicine; thereupon the committee was instructed to report fully. The report it produced was discussed by the Council in November, 1921, and certain recommendations were adopted which have since been under the consideration of the medical schools and licensing bodies. The relation of the Council to the universities and colleges is not such as to give it direct control over the medical curriculum. The licensing bodies have practical autonomy, so that the Council can only make recommendations, which may or may not be accepted. The action of the Royal Colleges in England, however, seems to foreshadow the adoption of the recommendations very much as they stand, for the Conjoint Board in England has issued new draft regulations in anticipation of the final discussion by the Council this month. Their effect can be gathered from the leading article on the medical curriculum published in this issue (p. 727).

DIAGNOSIS OF OBSTRUCTIVE JAUNDICE.

THE differentiation of obstructive from other forms of jaundice is often difficult, and yet vitally important because the former varieties of icterus may demand surgical treatment which would be of no value in jaundice of haemolytic origin or due to functional disturbance of the hepatic cells. The paper by Dr. McNee, which is published in this issue, gives an account of the test devised by van den Bergh for the purpose of distinguishing between these two groups of widely different origin. In principle it depends on the application to the examination of bilirubin in the serum of Ehrlich's "diazotization," which was introduced for another purpose and generally discarded as useless for that purpose. Van den Bergh found that the bilirubin circulating in the blood of patients suffering from obstructive jaundice reacts with the diazo reagent in a manner which differs from the reaction of bilirubin found in haemolytic jaundice or functional disease; the explanation suggested is that the pigment is bound to albuminoid substances in functional and haemolytic jaundice, and the union can only be broken down by time and alcoholic precipitation. The test can be performed very simply by mixing equal quantities of the patient's serum and the reagents, when if the case be one of obstructive jaundice a bluish-violet colour appears immediately, whereas in other forms of jaundice this colour does not appear at once; only after precipitation with alcohol is a violet-red colour obtained. The alcohol precipitation method may be used for quantitative estimation of bile in serum by a simple colorimetric method, a procedure obviously of great value for observing on the one hand progressively increasing obstruction as in malignant disease, or on the other the cessation of obstruction following the escape of a gall stone from the common bile duct, since the skin pigmentation in jaundice changes comparatively slowly. There are, however, bi-phasic reactions in which no clearly marked distinction between the direct and indirect test is obtained, but the information they supply is of value to the clinician in that they suggest that the jaundice is due to both obstructive and haemolytic or functional factors. The brief reports which Dr. McNee gives of cases demonstrate clearly the value of the test. Thus in the first two cases cited no operation need have been performed had reliance been placed upon the bilirubin test, whereas in Cases 3 and 4 it could have been foretold that the jaundice was obstructive in origin. Dr. McNee's paper is only a preliminary communication on the subject, and his further conclusions will be awaited with interest; but in the meantime this simple test seems to be of sufficiently established value for it to be more widely used.

SCIENTIFIC SECTIONS AT THE GLASGOW ANNUAL MEETING.

THE officers of the Section of Industrial Disease and Forensic Medicine at the forthcoming Annual Meeting of the British Medical Association in Glasgow have arranged the following provisional programme: An opening address by Professor Glaister, followed by papers by Sir Thomas Oliver, Sir W. H. Willcox, Dr. John Glaister, jun., and Dr. R. A. Lyster. For the discussion on "Stillbirth and neo-natal death," in the Section of Obstetrics and Gynaecology, on Wednesday, July 26th, the following arrangement has now been made: Dr. J. W. Ballantyne will speak on "Ante-natal, intra-natal, and neo-natal death: causes, pathology, and prevention, with special reference to ante-natal death"; Mr. Eardley Holland, on "Intra-natal death"; Professor A. M. Kennedy and Dr. F. G. Browne, on "Neo-natal death"; Professor Louise McIlroy, on "Ante-natal death due to toxæmia of pregnancy"; and Dr. J. N. Cruickshank and Dr. Gilbert Strachan will open the discussion. Two more items are now to be included in the programme of the Section of Anatomy: Professor T. H. Bryce will demonstrate a series of embryological models, and Dr. W. K. Connell (University of Glasgow) will read a paper on the form of the palate in children. The names of the officers of the nineteen Scientific Sections were published in the

SUPPLEMENT of February 18th, at p. 39. The Sections will meet on Wednesday, Thursday, and Friday, July 26th, 27th, and 28th, the mornings being devoted to discussions and papers, the afternoons to clinical and laboratory demonstrations. The five following two-day Sections will meet on the Wednesday and Thursday: Dermatology, Diseases of Children, Physiology, Industrial Disease and Forensic Medicine, Radiology and Electrolgy. Of the single-day Sections those of Anaesthetics and of Otology will hold their sessions on Wednesday; the Sections of Laryngology and of Tuberculosis will meet on Thursday; the Section of Anatomy on Friday; and the Section of Medical Sociology on Friday morning and afternoon.

MEDICAL PORTRAITS AT THE ROYAL ACADEMY.

THE one hundred and fifty-fourth exhibition of the Royal Academy of Arts, which opened to the public on Monday, is generally regarded by the critics as giving a very fair representation of British pictorial art at the present day, and in particular of the art of the portrait painter. Following the custom of recent years the exhibits are comparatively few in number and judiciously arranged; instead of a fatiguing mass of distant pictures far above the eye level, there are now restful grey walls. The many portraits in this year's exhibition include several of medical men and women. In Gallery IV there is a large portrait in oils by Walter W. Russell of Sir Norman Moore in the presidential gown of the Royal College of Physicians of London. The likeness is unmistakable, yet the portrait is a little disappointing, for the painter seems to have given almost overwhelming attention to the black and gold-laced robe. In Gallery III Frederic Whiting has been happier in his portraiture of Sir James Crichton-Browne, whose doctor's scarlet gown shows well against a black background, but is not unduly emphasized. On the opposite wall there is a portrait, by Solomon J. Solomon, of the Treasurer of St. Thomas's Hospital, a short distance away from the most remarkable of Orpen's six portraits. In Gallery VII will be found a quiet and pleasing portrait in oils of Dr. Jane Walker, by W. G. de Glehn; the effect would scarcely have been so good had the sitter worn vivid academic costume. The sculpture rooms contain a fine marble bust of Sir John Bland-Sutton, the work of Sir George Frampton; the profile is particularly effective. There is also, in this gallery, a charming bust of Miss M. Bostock, M.D., F.R.C.S., by Miss Isobel Donaldson. The works we have enumerated comprise all the medical portraits in the present exhibition, except a miniature, by Miss C. E. Wise, of Dr. V. H. Rutherford, formerly M.P. for Brentford, and a mezzotint by H. Macbeth-Raeburn, after Raeburn's famous portrait in the Archers' Hall, Edinburgh, of Dr. Nathaniel Spens, who was surgeon to the Royal Company of Archers. Mention may also be made of Anning Bell's portrait of Professor Lloyd Morgan, for many years a prominent teacher in the Bristol Medical School. In the black and white room there is a small etching of out-patients waiting in the dispensary of St. Thomas's Hospital. The architectural room contains designs for a number of medical institutions, including the Singapore Medical School, and the Institute of Medical Science at University College; also a very attractive sketch entitled "A Doctor's House, Westerham." The exhibition as a whole, if not of exceptional merit, is unusually interesting from many points of view.

IDENTIFICATION AND THE "VIEW" AT CORONERS' INQUESTS.

WE have received a communication from Dr. Waldo, coroner for the City of London, calling attention to the way in which the device for preserving bodies in the City mortuary has proved its usefulness. The apparatus, a French invention, by which the bodies are subjected to the action of formalin, was first provided some fourteen years ago, and more recently the local health authority has installed a similar apparatus in Dr. Waldo's court at Southwark. These are the only two mortuaries so equipped in the United Kingdom. On several occasions bodies have been identified

after periods during which, in ordinary circumstances, they would have become unrecognizable. In the same communication Dr. Waldo gives his reasons for advocating the retention of the "view" at coroners' inquests. Briefly, these are that the view affords the best evidence of the fact of death, that it prevents the hushing up of suspicious deaths by influential relatives and officials, that it has a deterrent effect upon evil-doers, and that it ensures the inquest being held in the vicinity of the place where the body is lying. He considers that but for the view a country coroner would be able, if he wished, to hold his inquiry in his own office, and summon the witnesses possibly from long distances away from the place where the body was lying. We agree with Dr. Waldo to the extent of retaining the "view" by the coroner, but we do not consider that any useful purpose is served by requiring the jury to view. In most courts this is now a purely perfunctory process, the jury merely glancing through a window into the mortuary at a body completely covered except for the face—a procedure which can in no way help the jury either to appreciate the medical evidence or to understand the cause of death. We are unable to follow Dr. Waldo's argument that the view acts as a deterrent to crime; nor do we understand how the view can prevent the hushing up of cases, since a decision to hold an inquest will already have been made before the view is required. It is understood that a bill is shortly to be introduced in Parliament for the purpose of amending coroners' law, and we hope its general trend will be to increase the sphere of usefulness of the inquest as a medical inquiry, since the purely legal points are already to such a large extent dealt with by other tribunals. Should this expectation be realized, we think it desirable for the coroner to view the body in every case, and his view might well include an observation of the part or organ which is concerned in the cause of death. This procedure would enable the coroner better to deal with the medical evidence, and would also have the advantage of strengthening the argument for appointing medical men to this office.

PROCEDURE IN THE DEFENCE OF INSANITY IN CRIMINAL CASES.

AN interesting case which calls attention to the position of undefended prisoners in criminal trials was heard at the Old Bailey last week. On April 26th a gardener was found guilty of attempted murder, the jury adding their opinion that the prisoner's mind was unbalanced at the time he committed the offence. The judge, Mr. Justice McCardie, then received a report from the medical officer of the prison to the effect that the man was suffering from melancholia when admitted to the gaol a month after the crime; that he subsequently developed suicidal tendencies, but was now sane. On April 27th the judge directed that the case should be reopened in order that the jury might have an opportunity of expressing formally their view as to whether or not the prisoner was of sound mind. The jury, without leaving the box, then returned a verdict of guilty but insane, and the prisoner was ordered to be detained during His Majesty's pleasure. On the first day the prisoner was undefended by counsel, but on the second day, at the request of the judge, he was so defended. The case led Mr. Justice McCardie to question the justice of the court practice which throws on the defence the onus of proving a prisoner's insanity, particularly when the prisoner is undefended by counsel. The rule was stated to be based upon the decision in the case of the King v. Oliver Smith in the Court of Criminal Appeal, but he was not in agreement with that rule and with the interpretations which had been placed upon it. It was not his practice on circuit to observe it rigidly, and he hoped it was not that of other judges. At the close of the case the judge asked Mr. Travers Humphreys, who had represented the prosecution on the first day, to express his views upon the matter. Mr. Humphreys said that the practice at that court varied as to whether the prisoner was or was not defended by counsel. In defended cases it had been consistently laid down from Macnaughten's case that insanity was an issue which could

only be raised by the defence, because every prisoner was presumed to be sane until the contrary was proved. It was the invariable practice to give the defendant's solicitor or counsel any evidence the prosecution possessed as to the state of the defendant's mind. The prosecution had also to see that the judge was in possession of all the material to enable him to make up his mind as to whether the issue of insanity should be raised even if the defence had not raised it. So far as he knew that was done in the present case. The report of one medical man (Dr. Young) was not in possession of the prosecution. It was merely an intimation for the guidance of the clerk of the court. The report of another medical man (Dr. East, medical officer of Brixton Prison) was before the judge and the defence. A difficult question arose when a prisoner was undefended, because a person who was insane in the view of the prosecution might believe himself to be sane and decline to raise the issue of insanity. In these circumstances the practice of Treasury counsel was to tell the jury that the issue might be raised, and at the close of the case to ask the judge whether he desired the prosecution to call any medical evidence which they had. The judge could always raise the issue, but the prosecution had not the right to do so if defendant did not wish it raised. Mr. Justice McCauley considered that that practice to a large extent safeguarded the position of the prisoner, but he was not at all sure that counsel for the prosecution in undefended cases were at the present day free from the responsibility of raising the defence of insanity. He would not lay down any definite rule—this case did not call for any—but he ventured to say that the decision in the case of the King v. Oliver Smith did not lay down any rigid or rigorous rule. The duty of counsel varied with the circumstances, and he was not satisfied that the decision in the King v. Oliver Smith represented sound practice or the existing practice of the majority of the judges. We agree that the procedure adopted in the Old Bailey reduces to a minimum the risk of injustice being done, and we hope that in courts where this procedure is not followed Mr. Justice McCauley's observations will be noted. The position of an undefended insane prisoner is one that calls for much sympathy, and legal technicalities should not be allowed to stand in the way of giving him every assistance in his defence.

MANY INVENTIONS.

AN article with the heading "Albert Abrams, A.M., M.D., LL.D., F.R.M.S., 'Spondylotherapy,' 'Electronic Reactions,' the 'Oscilloclast,' the 'Electrobioscope,' etc.," appears in the *Journal of the American Medical Association* of March 25th, 1922, in the section entitled "The Propaganda for Reform." Our contemporary states that Dr. Abrams is a native of San Francisco who graduated in medicine at the University of Heidelberg, Germany, in 1882; he "is a member of his local medical society, and through that holds fellowship in the American Medical Association." He has written voluminously, and in 1910 published a book on *Spondylotherapy*, which apparently deals with the same subject as that upon which osteopaths and chiropractors lay so much stress—the so-called "physiotherapy of the spine." In addition to this, Dr. Abrams has devised what he terms the "electronic reactions of Abrams." Remarkable claims have been advanced for these reactions. They are said to make long-distance diagnosis possible, for it is necessary only to send a few drops of blood taken from a patient and allowed to dry on a slide, when with the aid of certain instruments and devices a diagnosis may be made. According to the article in our contemporary it is asserted that from a fresh sample of blood spread over four square inches of blotting paper the sex, race, and disease of the patient can be determined by Dr. Abrams's method. Certain precautions must, however, be taken. The patient should face west, the blood should be taken in a subdued light, and there should be no strong red or yellow colouring material in the room. The most astonishing piece of apparatus seems to be the "oscilloclast." This device, we read, is not for sale. It can be had only on lease, and the first payment is 200 or 250 dollars, according to whether it is

wired for alternating or direct current; subsequently there is a monthly payment of 5 dollars. According to Dr. Abrams, all that is needed is to ascertain the "vibration rate of a drug," and then to substitute the same vibration as produced by the oscilloclast. Thus, if the "vibratory rate of atropine" be substituted for the drug itself, "the mouth dries or the subject feels as if it were puckered." Conversely, if the oscilloclast is switched to the pilocarpine vibratory rate, there is a copious flow of saliva. Dr. Abrams has extended his observations and experiments to a further device, the "electrobioscope," with which he has demonstrated the "sexuality of numbers and sounds." In this instrument if a pith ball is charged negatively and the numbers one to nine are marked on a narrow board and the vowels and consonants on another board, it will be found—according to Dr. Abrams—that even numbers repel the pith ball, while odd numbers attract it. Vowels likewise repel and consonants attract; a female hair repels and a male hair attracts. From these data Dr. Abrams draws the curious deduction that vowels and even numbers are female, consonants and odd numbers male. We may end by quoting the words of the *Journal of the American Medical Association*: "If there is any scientific foundation for the marvels that Dr. Abrams so picturesquely features, the scientific world has not yet found it out!"

SICKNESS AND INSURANCE.

MEDICAL men, we believe, are now more generally disposed than in the past to insure against the expenses and losses of sickness. This is a very commendable practice, more especially as the doctor has to face, not only the actual extra expenditure on himself when ill, but also, commonly, the payment of the fees of a locum tenens. The premium charged by insurance companies is governed by the extent of the expected liability, and should a medical man be so unfortunate as to have to make a large claim one year he does not wish to be told at the end of it that the insurance will not be renewed. Herein lies the value of a policy that covers all illness, including permanent disability, and one that cannot be ended by the company until the policy holder attains a certain age. The Medical Sickness Society, which was founded by doctors for doctors in 1884, has by the valuable work it has done helped to bring home to the profession the great importance of this class of insurance. The Society now has some thousands of doctors and dentists as members, but their number might advantageously be increased. The fact that the Society is purely mutual, has no shareholders, and pays no commission, enables it to offer a very comprehensive sickness and accident policy at the lowest rates obtainable, and permanent until the limit of age is reached. It undertakes also all classes of life assurance at low rates. Members of the profession can obtain all particulars from the Secretary, the Medical Sickness Annuity and Life Assurance Society, Ltd., 300, High Holborn, London, W.C.1.

PROFESSIONAL CLASSES AID COUNCIL.

THE Professional Classes Aid Council is in need of money. Mrs. Scharlieb, C.B.E., M.D., who was chairman of the Maternity Committee of the Professional Classes War Relief Council during the war, asks us to bring the need before readers of the *BRITISH MEDICAL JOURNAL*. "I know," she says, "how many doctors received help for themselves or for their families from the very judicious and helpful manner in which the council dispensed the funds entrusted to them." The council, owing to lack of funds, is now compelled to refuse applications for assistance in the education of children, grants in illness and convalescence, and other forms of help. Subscriptions may be sent to the Secretary, Professional Classes Aid Council, at 251, Brompton Road, S.W.3. The British Medical Association is represented on the council by its Treasurer, Dr. Haslip.

THE annual oration before the Medical Society of London will be given in the rooms of the society (11, Chandos Street, Cavendish Square, W.1) on Monday next, May 8th, by Mr.

H. J. Waring on "Hospitals: some suggestions as regards their future." The President will receive Fellows and guests at 8.30 o'clock, and the oration will be delivered at 9 p.m.; it will be followed by a conversazione.

The Croonian lecture will be delivered before the Royal Society on Thursday, June 1st, by Dr. T. H. Morgan, professor of experimental zoology in Columbia University, New York. The subject he has selected is the mechanism of heredity.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Budget for 1922-23.

THE essential facts of the Budget, described by Sir Robert Horne on May 1st, fall within narrow compass. Its basis is that on existing taxation the revenue would be £356,625,000 against an expenditure of £910,069,000, giving a surplus of £46,556,000. But this surplus was reached apart from the usual consideration for debt repayment or allowance for the Sinking Fund. After pointing out that the country had provided during the last two years £322,000,000 in cash for the redemption of debt, the Chancellor of the Exchequer presented arguments for a breathing space in the matter of debt repayment. He dwelt upon the unparalleled depression in trade, and upon what it meant in unemployment to an extent unknown before, and in privations for the professional and middle classes such as they had never previously had to face. There were, however, hopeful signs of revival which with a little encouragement might develop into solid progress. He claimed that in the circumstances the Government would be justified in suspending the Sinking Fund, and proceeded to state how they proposed to apply the surplus already indicated. He dealt first with postal rates because the Post Office had provided a profit, and explained that he had agreed with the Postmaster-General that the Sunday collections (but not deliveries) should be restored; that the postcard rates should be reduced to a penny; that the minimum in postal charge for printed papers should, subject to certain conditions, be reduced from one penny to one halfpenny on packages not exceeding one ounce, the rate for two ounces to remain as now—one penny; that the minimum charge for inland letters should be reduced from twopenny to threehalfpence for one ounce, and for Empire and U.S.A. letters from twopenny to threehalfpence for one ounce; and that certain reductions should be made in telephone charges, at a cost of about a million sterling. The total cost of these concessions for the present financial year would be about £5,650,000. The postal changes would come into effect at the end of May.

The general reductions which Sir Robert Horne announced were: 1s. in the £1 off Income Tax at a cost, in the present year, of £32,500,500, and a reduction of 4d. per pound on the duty on tea (with a reduction of one-third on the linked-up duties on coffee, cocoa, and chicory) at a cost of £5,000,000 in the present year. Earlier the Chancellor had announced a reduction in the basis of assessment of agricultural land to one-third the annual value (which, with certain concessions, for amenity lands would cost £1,100,000 this year) and some alterations in Income Tax law and the incidence of the Excess Profits Duty. The former would cost the country this year £700,000, the latter £2,000,000. Sir Robert Horne did not explain how the reduction in Income Tax will apply to incomes now paying less than 6s. Mr. Hilton Young, Financial Secretary to the Treasury, however, stated later that though the basic rate was reduced by 1s. it did not follow that the income tax of all persons would be reduced by 1s. in the £. The reduction of the basic rate by 1s. resulted in the reduction "of all our income taxes by one-sixth." It appears, therefore, that, while the 6s. charge will be reduced to 5s., the 3s. charge on a lower scale of income will be reduced to 2s. 6d. It was promised that a table showing how the tax worked out would be made available in a few days.

Thus Sir Robert Horne showed a balance sheet which would leave, at the end of the present financial year, an estimated surplus of £706,000. In regard to the Sinking Fund he explained that, as contractual liabilities would have to be met, money would have to be raised for that purpose, but this would not actually increase the debt. It should be added that a number of minor points were dealt with not involving any large financial considerations for the State. The Chancellor said that in face of a House of Lords' decision, which had overthrown the practice of sixty years in regard to the assessment of Income Tax for employees of public companies, he should propose legislation upon their

salary or remuneration for the current year. In reference to charity legacies representations had been made to him, particularly by the hospitals, as to the position arising out of the decision of the House of Lords in the case of Dr. Barnardo's Homes. In that case it was held that the charity could not claim exemption from income tax on the income from residuary estate, except as from the time when the residue was actually paid over. This, though not a large matter, had occasioned a considerable amount of hardship, and he proposed to remedy the grievance. He also intended to include in the Finance Bill proposals for increasing the normal flat rate repair allowance in the case of small houses, and for enabling claims to be made for the actual cost of maintenance, and not only in the cases now authorized, but in the case of all lands and houses of whatever value. The Budget contains no relief for the owners of motor vehicles. The motor vehicle duties, which were estimated to yield last year nine millions, actually yielded two millions more. The estimate for 1922-23 is £10,600,000.

In the course of discussion which followed Mr. Asquith was the chief speaker. Mr. Hilton Young, winding up the debate, referred to questions raised as to the hardship inflicted by the Corporation Profit Tax upon various corporations instituted for philanthropic or other beneficial purposes and promised sympathetic consideration to the appeals made.

It should, perhaps, be said for clearness that the reduction in the Income Tax does not affect demands already issued as it applies only to the financial year which began in April, 1922; and in regard to which the first demands are made on January 1st next. The return on which the Budget was based shows that the amount owing to this country by the Dominions and Colonies was one hundred and fifty millions, and by the Allies, excluding Russia, nearly twelve hundred millions. Relief and Reconstruction Loans amounted to thirty millions, of which twelve millions were to Austria. The sums lent to Russia amount to over six hundred and fifty millions.

The Education Vote.

Introducing, on April 27th, a vote of £27,900,000 for education purposes, Mr. H. A. L. Fisher said that the total estimate of £44,900,000 showed a decrease of £5,104,653 as compared with that of last year. Of this economy the sum of £1,205,633 was due to the fact that many students who had been undergoing a course of instruction at the universities and other places with the aid of grants from the Board had now completed these courses.

Touching the magnitude of the work of the Department, the Minister said it had to deal with 20,000 public elementary schools with nearly six million children on the registers; with over 1,200 secondary schools containing more than 350,000 pupils; with technical and evening schools, schools of art, university tutorial classes, continuation schools, etc., over 5,000 in number, with nearly a million students; and with over one hundred training colleges and departments for teachers, with about 14,000 students in training. The Minister referred also to other particular services and claimed that in all the circumstances the staff at headquarters could not be deemed excessive. The expenditure on special services, which would be recognized by a grant to the extent of 50 per cent. of that expenditure, was to be limited to £3,400,000, which was less by £754,000 than the local education authorities' revised estimate, and this reduction would be accounted for chiefly by a diminution of £730,000 in the provision of meals, which in 1921-22 reached the abnormal figure of £1,030,000. It was no part of the Government policy to curtail any expenditure really necessary to preserve our child population in bodily health. That would be the worst and most ruinous form of waste. But so vast an expansion of the *elemosynary treatment* of school children as had been witnessed lately was not, correctly speaking, an educational function, the cost of which should fall upon the education rate or upon the vote of the Board, and so they proposed to limit the sum chargeable on the vote in respect of the provision of meals to £150,000, which was more than sufficient to meet the normal claim in a normal year. Abnormal claims arising from great waves of unemployment should be met out of other funds.

The School Medical Service.

Coming to the medical service proper, Mr. Fisher said he should be very sorry to see any damaging economy either in the sphere of medical inspection or in the treatment or management of special schools. The school medical service inspected over two and a half million children every year, while the attendance of the children at the clinics ran to many millions annually. The cost to the Exchequer of all this work amounted to about 2s. 6d. per head of the six million children in average attendance at public elementary schools. On such figures he thought it could not be regarded as extravagant: the cost had increased, but so also had the value. He could not give complete figures for the country, but he had them for twenty-four areas, including the London area. Comparing the attendances at school clinics in these twenty-four areas for the years 1914 and 1920, he found that in the first named the attendance was a little over 700,000, and that in the latter it was a little over three millions. As the result of this work there had been an improvement in the cleanliness of school children amounting almost to a revolution, and a great and progressive improvement in regard

to dental defects and defects of vision while hundreds of thousands of children had had their physique and powers of resisting disease improved, with the result that in the case of some five hundred thousand children vast masses of and mortality had been prevented. The local education authorities expenditure recognized for grants without any real injury to the service. There was, as he had explained, a limitation of £3,400,000, but most of the reduction was on the cost of feeding in schools. He did not say that there was no field for economy in the special schools. He was carefully examining the matter, and the Board would shortly publish revised regulations which would facilitate a reduction in the cost of schools for defectives without lessening the number of children who benefited from this form of care and treatment. He placed in a special category the schools for the blind and the deaf; they were very costly; much diminution could scarcely be expected, having regard to the attention required. Marvellous results were attained. In the other special schools the staff could be arranged on a more economical basis.

Debate.

In the course of the discussion, Mr. Asquith asked for an assurance that the question of a reduction of grants to local universities would be given an opportunity for real discussion on the Treasury vote. Mr. Fisher said that on request through the usual channels time would certainly be afforded.

Touching the means of access from the secondary schools, Mr. Acland said that his experience as Chairman of the London School of Medicine for Women at the East London College taught him that there was provision to help really had come across cases who £200 or £210 a year, had screwed and pinched so as to afford first one daughter and then a second the extraordinary expense of a medical training, and it was heartbreaking that all the State gave to help the training of a particularly promising pupil was an exhibition of £10 or £15 a year.

The debate was adjourned.

Dangerous Drugs Acts.—In reply to Mr. Ramsden, on May 1st, the Home Secretary said he had no power to order that twelve strokes of the cat, in addition to imprisonment for six months or more with hard labour, should be given to vendors caught illegally selling cocaine and similar drugs. The penalties were fixed by Section 13 of the Dangerous Drugs Act, and could not be altered without legislation. The maximum penalty allowed by the Act for a first offence—six months' imprisonment with hard labour, or a fine of £200, or both—ought, in his opinion, to be a sufficient deterrent, and he could not undertake to introduce amending legislation of the nature suggested.

Latest Pensions Statistics.—Mr. Macpherson, on April 26th, informed Mr. Alfred Short that the approximate number of Officers 32,000, nurses 1,400, officers' widows 9,600, officers' dependants 8,600, men 390,000, widows 159,000, dependants 362,000, motherless children 17,000. There are in addition allowances paid in respect of 1,140,000 wives and children of disabled men and 338,000 children of widows.

Disability Pensions.—On question by Mr. Maclean, on April 6th, Mr. Macpherson said the Ministry of Pensions was bound by and accepted without question a decision of the Pensions Appeal Tribunal that an appellant's disability was attributable to or aggravated by service, and therefore awarded compensation on the basis of the degree of disablement then found by a medical board to exist. When the disablement was less than 20 per cent., compensation took the form of a gratuity or a final weekly allowance.

Condensed Milk.—In reply to Mr. Doyle, on May 1st, Sir Alfred Mond said that his predecessor appointed a committee to consider the question of fixing standards for condensed milk, and draft regulations were prepared to give effect to the recommendations of the committee. It appeared, however, that there was no general agreement as to the standards to be fixed, and he therefore decided not to proceed with the regulations. He was not aware of any sufficient reason for fixing a standard for dried milk, as there could not be any misapprehension as to the degree of condensation of the product and any adulteration could be dealt with under the Food and Drugs Act. On the same day Sir A. Griffith Boscawen informed Mr. Doyle that the quantity of condensed, separated, or skimmed milk imported into the United Kingdom in the first three months of 1922 was 273,230 cwt., as compared with 157,112 cwt. in 1921, and 82,901 cwt. in 1920. The proportion of this which was machine-skimmed could not be stated. Mr. Baldwin, in reply to an earlier question by Mr. Doyle, said that the importation of machine-skimmed milk was prohibited in many countries; but he was not prepared to introduce legislation on this subject.

Sewage Purification.—In reply to Lieut.-Colonel Pownall, on May 1st, the Minister of Health stated that his attention had been drawn to the experiments of Dr. Reusch and Mr. Fairbrother as to the value of dyes in sewage purification. Further research was necessary, and he was making the necessary inquiries.

Answers in Brief.

The approximate amounts of income tax and super-tax due to be paid but remaining unpaid on March 31st, 1921 were: Income tax (excluding the instalment due on July 1st, 1921) £86,000,000; super-tax £17,000,000. The amount of Corporation Profits Tax in assessment but unpaid (less sums due to be remitted) was £3,000,000.

CONDITIONAL NOTIFICATION OF VENEREAL DISEASE.

A CONFERENCE, called by the Mayor of Paddington, was held at Paddington Town Hall on April 28th to consider certain proposals put forward by the Paddington Propaganda Committee of the National Council for Combating Venereal Diseases. This scheme would make venereal disease notifiable in certain circumstances.

Mr. ARTHUR R. MORO, Chairman of the Committee, explained the proposals. He said that an average of from 50 to 60 per cent. of the persons attending the free clinics discharged themselves before their condition had become non-infectious. In view of the terrible harm which might be wrought by such people, he thought the general feeling would be that, even if some of the proposed measures did produce a certain amount of inconvenience or even hardship, the sacrifice would be worth while. In dealing with the difficult problems involved, the aim steadily to be kept in view must be (1) to check the spread of disease and protect the innocent, and (2) to cure the patient with as little inconvenience to him as possible.

The Paddington Scheme.

The scheme put forward by the Paddington Propaganda Committee was as follows:

1. Patients, when consulting a doctor or attending a venereal diseases clinic, should be warned that they must continue treatment until such treatment was completed. If, after the warning, they failed to be treated, their cases should be notified to the medical officer of health, whose duty it would be under the Health Acts to take the necessary proceedings.
2. In-patient accommodation must be provided for patients who, being in an infectious state, and a danger to the community, were not in a position to be treated to their own homes. In certain cases power of detention might be necessary.
3. It was proposed to add these diseases to the list of infectious diseases, which would automatically take them outside the civil law of libel; but it was considered that it would be necessary to safeguard the patient by making medical men liable if they improperly divulged private information obtained in the course of their practice.
4. In framing instructions it would be very useful if, instead of only warning the public of the danger they were in of contracting disease, it were explained to them how infection was not carried, and that, so long as a patient was not in an infective state, it was quite safe for him to go about his daily work and mix with others.

It would be seen (Mr. Moro continued) that this scheme for notification differed from ordinary notification of contagious diseases in that notification would here come into force only when a patient refused continuous treatment or was neglectful or recalcitrant, becoming thereby a menace to the safety of those with whom he was associated. Under this scheme doctors would be able to observe professional secrecy so long as secrecy did not imperil the health of others. The need of power to enforce continuous treatment was urgently felt at every clinic, in every infirmary, and by most medical men. Patients were constantly discharging themselves before they were cured, and they often resumed a manner of life which must spread the disease to others. Case after case could be cited in corroboration of this statement, and yet no powers of restraint existed, and no protection by law was given, and thus the disease was carried down to generation after generation of innocent children. How could any practical steps be taken until the doctors were free to act on behalf of the public? Doctors were silenced by the laws of libel and slander, as well as by custom and convention. The voice of public opinion alone could release the profession from these restrictions. He concluded by moving:

That this Conference is of opinion that some form of modified notification of venereal diseases (which shall be enforceable only when a patient refuses or neglects to continue treatment) is needed to check the spread of these diseases and to protect the public.

Support for Modified Notification.

Mrs. R. P. WETHERED, honorary secretary of the Associated Societies for the Care and Maintenance of Infants, seconded the motion. She said that until the law of libel was modified doctors would be powerless to protect the public. The existence of a system of notification would set them free. In fact, it would become a statutory obligation upon them to protect the public from a patient who was a source of danger.

Mr. E. B. TURNER, F.R.C.S., who supported the motion, said that it would not be possible to do anything in this matter until public opinion had been educated; but when the people were educated they would quickly come to the conclusion that everything possible must be done to ensure that those who came for treatment for venereal disease carried that treatment to its conclusion.

ENGLAND AND WALES.

736 MAY 6, 1922]

A letter in favour of the proposals was read from the Bishop of Kensington; and the Rural Dean of Paddington and the chairman of the Public Health Committee of the borough of Hampstead also supported the motion, which was carried unanimously.

Sir HENRY HARRIS, M.P., urged an official inquiry into the question of modified notification, for which, he said, the time was fully ripe. He moved:

That the Ministry of Health be urged to appoint a committee of inquiry, to consist of medical men and laymen, to consider the question of modified notification and compulsory continuous treatment of venereal diseases and to hear evidence.

With the addition of the words "and women" after "laymen" this motion also was carried unanimously.

England and Wales.

HUGH OWEN THOMAS MEMORIAL LECTURE.

THIS lectureship was founded in 1920 by friends and admirers of the great Liverpool orthopaedic surgeon. The lecture is to be delivered triennially in the Liverpool Medical Institution, and is to deal with a subject bearing directly on orthopaedics; the lecturer is appointed by the Council. Most appropriately for his subject, "Hugh Owen Thomas—the man and his work." The lecture was delivered on April 25th before a large audience, many of whom had known Mr. Thomas. Sir Robert, who had been intimately associated with Hugh Owen Thomas for over twenty years, gave an interesting account of his life. He received his early education in Anglesey, where he spent his boyhood for reasons of health. When 17 years old he was apprenticed to his maternal uncle, Dr. Owen Roberts of St. Asaph, a great friend of Sir Benjamin Brodie. Later he pursued his studies at Edinburgh the days of Goodair and Syme, with Turner as demonstrator anatomy. He then proceeded to University College Hospital, London, and in 1857 obtained the diploma M.R.C.S. He returned to Liverpool, where he practised until his death in 1891. He was descended from seven generations of bone-setters who lived in Anglesey, and showed great ingenuity and inventive skill in the treatment of accidents (dislocations and fractures), deformities, and diseases of the joints. He devised and made his own appliances. He laid great stress on the careful fitting of splints and their correction from time to time under his own supervision. A keen observer of Nature, he realized the truth *natura non facit saltus*, and recognized the supreme value of rest in the treatment of diseased joints. The appliances, though simple, were the outcome of much thought, and their final perfection represented many years of careful study and minute observation. By means of his splints patients instead of being bedridden, enabled to enjoy fresh air and exercise—a great improvement, indeed, in the treatment of tuberculosis of the joints. Of the value of the Thomas splint in the treatment of fractured the femur, the great war has furnished ample evidence. Hugh Owen Thomas revolutionized the treatment of palsied limbs through his observations on paralysed muscles. His treatment of delayed union of fractures by damming of the circulation anticipated Bier's method by many years. He introduced an ingenious plan for wiring fractures of the lower jaw, which was first published in 1871. Although Hugh Owen Thomas never held a hospital appointment, his private clinic—free to the poor on Sundays—was thronged with patients of all classes. It was the resort of distinguished surgeons from all over the world, and his ideas—not infrequently filched and published by others as their observations—were in those days far better known in distant parts than in his own town; but time has amply confirmed Thomas was not a robust man, and his portrait shown on the screen confirmed this; but he was an indefatigable worker, and left nothing to chance in his treatment of his patients—rich and poor alike. Giving the impression of being brusque at times, he was in reality a kind-hearted man. In conversation he brushed aside irrelevancy, and came quickly to the point. He was much interested in all kinds of mechanical invention, and one of the last papers he wrote was on the method of propulsion used in ships by the Romans. He passed away at the comparatively early age of 57.

Sir Robert Jones showed on the screen pictures of Thomas working at his lathe, and red-

dislocation by means of a spinal apparatus and of various instruments he devised.

Mr. Rushton Parker, who was a friend of the great surgeon and did much in introducing the use of the Thomas splint into hospital practice, proposed a vote of thanks to Sir Robert Jones for his lecture. Mr. W. Thelwall Thomas seconded, and incidentally mentioned that the funeral of H. O. Thomas was the largest on record in the annals of the city of Liverpool.

The personal note in the lecture was much appreciated by the members present, and it was felt that the medical profession in Liverpool had just cause for doing honour to the memory of an illustrious member.

SOUTHAMPTON MEDICAL DINNER.

The annual dinner given by the doctors in Southampton and neighbourhood was held at the South-Western Hotel on April 19th. Nearly fifty practitioners were present, the gathering being confined to the profession only, and a very pleasant evening, with speeches and song, was spent. The opportunity was taken to make a presentation to Dr. MacKeith of Southampton, who was the first to organize and start the arrangements for looking after the practices of those medical men who served abroad during the war. It took the form of a piece of plate, and bore the following inscription:

"Presented to Dr. A. A. MacKeith by the Southampton doctors who served overseas in the great war 1914-1918, as a mark of gratitude for, and appreciation of, all the work done for them during their absence by him and the Southampton medical men."

A large proportion of the doctors in the town and neighbourhood were present, and an equally successful meeting is hoped for next year. The honorary secretary is Dr. Joshua Keyms.

CENTRAL MIDWIVES BOARD.

At the meeting of the Central Midwives Board for England and Wales on April 27th, with Sir Francis Champneys in the chair, two penal cases were heard. One midwife was struck off the Roll, and judgement on the other was postponed. The ordinary monthly meeting was then held, and Sir Francis Champneys was re-elected chairman. Professor Henry Briggs, who occupied the chair temporarily, made a few warmly appreciative remarks regarding the valuable work done by the chairman of the Board for so many years. Sir Francis Champneys, on resuming the chair, feelingly acknowledged the words spoken by Professor Briggs on behalf of himself and the Board. It was resolved that the terms and conditions of Section 10 of the Midwives Act, midwives holding the certificates of the Midwifery Authority in New Zealand, provided that midwives holding the certificate of the Central Midwives Board are afforded reciprocal opportunities of being admitted to the Midwives Roll of New Zealand. The Board decided to inform a commercial firm of its disapproval of midwives acting as advertising agents, and to point out that midwives acting in such a capacity render themselves liable to proceedings before the Board.

With reference to suggestions made by Sir George Newman, regarding the administration of drugs by midwives, it was resolved:

- That the reasoned statement in support of the Board's views that midwives should not be debarred from administering drugs, as provided by Rule E 19, which has been prepared by the members of the deputation to the Ministry of Health, be approved, and that copies of the statement be sent to the Local Supervising Authorities and other bodies who have made representations to the Board.
- That the Board thinks it inadvisable to suggest to teachers and midwives the drugs which it thinks should be used by midwives in various emergencies.

A motion was adopted, suggesting that the power to inspect lying-in institutions, at present possessed by a few local supervising authorities under local Acts, should be extended to all local supervising authorities, and requesting the Ministry of Health to endeavour to arrange for legislation to give effect thereto.

TRAFFIC FATALITIES IN LONDON.

Suggestions for the avoidance of street accidents have been made by the city coroner, Dr. E. J. Waldo, during recent inquests. In the case of a boy who was run over and killed just outside his school it was suggested that the placing of a constable on fixed point duty (in place of patrol constables) and the erection of sign boards at definite points on the tram-lined roads in the London area, as has been already done in

Southwark, would be measures of safety. At another inquest it was brought out that metropolitan constables might be quite ignorant of first aid; since the war a qualification in first aid has been voluntary: the fee must be paid by the constable, and he has to attend the course in his own time. Dr. Waldo expressed the view that qualification in first aid should be compulsory, and the jury recorded its opinion that every metropolitan police constable should be obliged to give proof of efficiency in first-aid treatment, that attendance on the classes should be in service time and paid for by the County Council or out of the police fund. Dr. Waldo has also pointed out that the London County Council ambulance stations—six in number, with eight ambulances—are quite inadequate for the metropolitan area of 117 square miles.

Scotland.

THE PARIS FACULTY OF MEDICINE.

A MEETING of the University Court of the University of Edinburgh was held on April 24th, with Principal Sir Alfred Ewing in the chair. The Court approved very cordially of an invitation which had been conveyed by the Faculty of Medicine to the Dean of the Faculty of Medicine of the University of Paris and certain of his colleagues to visit Edinburgh University as the guests of the Faculty next July. The Principal stated that the University was under great obligation to the Faculty of Medicine of the University of Paris for the facilities which it had given, and the hospitality it had shown, to medical students from Edinburgh.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

The summer course under the auspices of the above association has now begun. Clinical courses in medicine, surgery, and a variety of special subjects are offered, and a limited number of whole-time and part-time clinical assistantships are available. For the ordinary courses enrolment may be made for periods of a month or more, but in the case of clinical assistantships the period of enrolment must not be less than three months. Full particulars may be obtained from the acting secretary at the university. Under the syllabus arranged post-graduate work is available from May to October.

GLASGOW MEDICAL APPOINTMENTS.

The appointment is announced of Dr. John F. Smith to the post of Physician for Diseases of the Skin at the Glasgow Royal Infirmary in succession to the late Dr. George McIntyre. Dr. Smith also becomes a Lecturer on Diseases of the Skin in Glasgow University. Dr. W. R. Inglis Pollock has been appointed Visiting Surgeon to the Glasgow Eye Infirmary, thus filling the vacancy caused by the death of Dr. W. Cochrane Murray.

Ireland.

WOMEN'S HEALTH ASSOCIATION.

At the annual general meeting of the Women's National Health Association in Dublin, at which the Marchioness of Aberdeen and Temair presided, Dr. Alice Barry said that the Babies' Clubs had been progressing satisfactorily. Early last year their work was co-ordinated with that of the Infant Aid Society. The total number of deaths during the year was 1,150. Of that number 50 per cent. had been registered under the Public Health Act; efforts to trace the other 50 per cent. had failed. Thirty-seven deaths occurred among the babies attending the eight clubs. There was much unrest during the period under review, but in spite of that and of unemployment mortality among children had declined. The mothers on the books numbered 4,893, and the nurses paid 38,229 visits to members. The number of attendances at clubs was 16,139 mothers and 23,518 children. Mrs. Dwyer said that during the last year lectures and demonstrations on the care of children, and the making and remodelling of garments, were given at the Babies' Clubs affiliated to the association, and also at Rathfarnham and Swords. Lectures on first aid, home nursing, and infant welfare had been given to the patients at Peamount Sanatorium under the auspices of the Department of Agriculture, by which grants in aid were given.

Miss Hackett presented the report of the Central Committee, which gave a detailed account of the patients and their families who had been at one time or another in one of the sanatoriums. The President read the report of the Medical Research Committee, which had investigated some 2,000 cases. Sir W. Thompson reported that the number of patients admitted to Rosslare Sanatorium during 1921 was 91, and that the total number of patients there was 138. The great trouble in all sanatorium treatment was that patients were admitted too late. Only 12 per cent. were received in time; not less than 60 per cent. were found to be in an advanced stage, and the balance were in a very advanced stage, and not proper patients for a sanatorium, but for special institutions for such cases. In 10 per cent. of the cases dealt with the disease was cured, in 20 per cent. there was improvement, and in another 20 per cent. further improvement. A resolution was adopted asking that a home be established in each county for the treatment of advanced cases of tuberculosis.

Sir Andrew Horne, alluding to the work of the Babies' Club Committee, said that not only the value but the extent of the work was increased. There was great mortality among babies in Dublin, and the object of the association was to teach mothers how to cook food and how to feed children. He was glad to be able to say that the people themselves were taking the greatest interest in the work.

Correspondence.

ETIOLOGY AND TREATMENT OF DIABETES.

SIR,—Dr. Renshaw and Mr. Fairbrother are to be congratulated on their attempt to open a new approach to the problem of diabetes and acidosis in their article in the JOURNAL of April 29th (p. 674). Their paper, however, seems a striking example of the divorce between clinical medicine and laboratory work, for no clinical details of the cases are given, nor is there any mention of the diets, although it is a notorious fact that in the past much laborious work upon the faeces has been wasted by the failure to indicate the diet upon which the results were obtained. May I as a clinician much interested in these problems be allowed to use your space for some critical remarks?

The conception of a primary acetone formation with secondary failure of the sugar-burning mechanism seems worthy of very serious consideration for the following reasons: (1) Acetone has some very similar pharmacological reactions to chloroform and the narcotics, which, as we know, are liable to upset the carbohydrate metabolism. (2) Some cases where the ketosis (or acidosis) is apparently primary, or at any rate antecedent, such as toxic vomiting of pregnancy, have a diminished sugar tolerance. (3) In cases of diabetes under dietetic treatment it is very common to see the sugar and the diacetic reaction wane and finally disappear at the same time. (4) In the determination of a suitable "maintenance diet" for a diabetic it is possible to increase the total energy value of the diet by increasing the fat quotient at the expense of the carbohydrate and protein quotients. If this is done to an excessive degree we may get a stormy onset of acidosis (usually associated with sugar), but even if we avoid this it is found that the sugar tolerance sinks gradually in the course of weeks. This necessity for preserving a proper balance between the carbohydrates and fats has been emphasized by Joslin, and an intelligent patient soon recognizes the fact. It seems possible that an acidosis or ketosis may be a factor in this phenomenon. The possibility therefore of a primary acidosis or ketosis is one not lightly to be put aside.

The conception of an enterogenous formation of acetone bodies in acidosis is not new, having been discussed about thirty years ago by Lorenz. References to the early literature may be found in Schmidt and Strasburger's monograph, *Die Faeces des Menschen*, where it is emphasized that even when there is no acetone to be found in the faeces, yet the possibility of its originating in the intestines cannot be lightly dismissed.

The case presented by Dr. Renshaw and Mr. Fairbrother, however, appears entirely to disregard certain well-established clinical facts. If a young diabetic, whose urine contains both sugar and acetone or diacetic acid in large quantities, is placed upon a diet of oatmeal (2 oz.), lean meat or fish (2 oz.), and cabbage or other "5 per cent." vegetables for a few days it will be found that the sugar and diacetic acid diminish or disappear *pari passu*. With this diet the strict fasting is

very rarely necessary, in my experience, yet it would appear to be an ideal culture material for the bacillus under discussion. One of my patients, who was put temporarily upon a maintenance diet containing four pounds of cabbage, did not turn up for a whole year. I suggested that his diet could be much improved, but he preferred to let well alone and stick to the cabbage. He had stuck to the diet and had no return of glycosuria. His old acidosis had entirely disappeared, although he had eaten so much decaying cabbage during last summer's drought that he had been for a time yellow. Here was a man (at one time on the verge of coma) eating the food under suspicion who had not only avoided acidosis but recovered from an existing acidosis. The use of 5 per cent. vegetables has been found so useful on empirical lines that it is hardly justifiable to discard it for theoretical reasons.

It is stated (p. 676): "Occurring as it does on decaying vegetable life it is easy to understand how such a heat-resistant, spore-forming organism should enter the alimentary canal." The diet of the patients is not described, nor are we told that the healthy controls who gave negative results were on the same diet. It is also important that we should know how many experiments were done on each control as compared with the laborious attempts to isolate the organism from the refractory cases of diabetes. The conclusion which appears quite legitimate is that an acetone-forming organism, resistant to heat, lives upon cabbages, which form a large part of the present-day diet of most diabetics; hence it is found in their faeces and not in those of healthy persons living on a normal diet. There may be data available by which this conclusion may be combated. Hence this letter.

One other minor point: Is it wise to let lay newspapers have an advance copy of the JOURNAL? Personally I got one trunk call on Friday night and two more inquiries from patients before I had time to read the article on Saturday night.—I am, etc.,

Sheffold, April 30th.

A. E. BARNES.

* * Our correspondent's assumption that advance copies of the JOURNAL of last week were supplied to lay newspapers is natural but erroneous. We must leave Dr. Renshaw and his colleague to explain the occurrence.

SIR,—Numerous attempts have been made to refer diabetes mellitus to a bacterial infection of the alimentary tract, and treatment based upon this supposition has been repeatedly tried, with unsatisfactory results. The communication in the JOURNAL of April 29th (p. 674) by Dr. Renshaw and Mr. Fairbrother once more raises the question, but in a slightly different form, since they claim to have discovered a new and specific organism. If this claim could be substantiated it would no doubt revolutionize our treatment of the condition, but the evidence at present available is not convincing. It is true that they have isolated the organism in question from the faeces of five or six cases of severe diabetes and failed to separate it from the stools of eleven non-diabetic persons; they have also cultivated it outside the body in suitable media, thus fulfilling the first two of Koch's postulates, but they have apparently not attempted to comply with the remaining two, which are the true test of specificity. As matters stand at present, it may well be that the organism they describe is more easily cultivated from the faeces of the diabetic than the non-diabetic individual simply because the conditions in the intestine of the former are more suitable for its growth than in the latter—that is to say, it is an effect rather than a cause of the disease.

In this connexion it is to be noted that even with diabetic stools "heavy inoculation" of the medium appears to be necessary to obtain a satisfactory growth. Further, it is strange that if, as they say, the organism flourishes best in carbohydrate media and is the cause of the acetoneuria in diabetes, acetone previously present should usually diminish when carbohydrate foods are administered or increased. If this organism is not present in the intestine of non-diabetics, why should acetoneuria appear and increase as a result of starvation?—I am, etc.,

P. J. CAMMIDGE.

London, W., April 28th.

BONE GRAFTING IN UNUNITED FRACTURE.

SIR,—In the attempt to deal successfully with ununited fracture by bone grafting it should be worth the while of surgeons to learn, and adopt, a procedure not only most easy to the surgeon but least risky to the patient.

At a meeting of the Surgical Section of the Royal Society

of Medicine on April 5th (BRITISH MEDICAL JOURNAL, April 15th, 1922, p. 602) Mr. C. Max Page and Mr. G. Perkins dealt with the technique of bone grafting in a manner both able and practical, as far as the grafting "in mass" is concerned for the repair of ununited fracture. The results seem to have been very successful on the humerus—only one failure out of six. On the radius nine consecutive cases all succeeded. Out of seven grafts on the ulna there were five failures, and among seven grafts on the tibia there had been three failures, so that the sum of success can hardly be said to be striking. But these authors made no reference to the implantation of small fragments between the ununited bones, after clearing away the soft connecting medium, as described and illustrated by me at a meeting of the Surgical Section on June 16th, 1908, and briefly recapitulated at a meeting of the Section in Liverpool in June, 1914.

It is true that the meeting in London was the last of the season, and that my paper was by its late turn relegated to the end, by which time most of the Fellows had left, no doubt tired out, like myself, by the previous proceedings crowded in. But the details were fully related, with clear descriptive photographs well displayed by means of the epidiascope. The cases were only two in number, one having occurred in the last year, and the other in the last month, of my hospital duty (May and September, 1907). The former was in the humerus of a strong working man of 35, the latter in the ulna of a woman aged 48, both on the left side.

In the case of the man the fragments were taken from the callus on the fractured ends; in that of the woman there was no callus, but fragments were clipped from the ununited ends. In both cases the fragments were placed in the blood which had oozed during the operation, after the fibrous medium connecting the bones had been dissected away. The muscles and integuments were stitched over the gap, and splints applied over the surrounding gauze dressing.

In both cases complete success resulted, and I had only to regret that the end of my hospital practice left me no further opportunities. I should have particularly wished to try it in the thigh, in which the difficulty and danger of more formidable procedures are only too well known. The method I refer to is beyond all comparison easier for the surgeon as well as safer for the patient, and the splints required the same as in the case of primary fracture (compound). I could not resist venturing to remark to the secretary at the meeting that the process I was about to relate was, I feared, much too easy to commend itself to other surgeons, who often seem more fond of complications than of simplicity. But I can still assure them that it is worth while, and can only once more refer them to the printed and illustrated report (*Proc. Roy. Soc. Med.*, vol. i, part 3, p. 232, 1908; vol. vii, part 3, p. 275, 1914).—I am, etc.,

RUSHTON PARKER,

Professor of Surgery in the University of Liverpool.
Liverpool, April 24th, 1922.

EXCISION OF HEAD OF FEMUR IN ARTHRITIS DEFORMANS.

SIR,—Mr. Platt's paper entitled "Excision of the head of the femur in arthritis deformans" (*BRITISH MEDICAL JOURNAL*, April 29th) raises a question which is of more than mere academic interest—namely, when does such an operation cease to be "excision of the head of the femur" and become what is now universally known as "arthroplasty"?

Mr. Platt himself says that the operation which he describes is "somewhat different" from the classical excision of the hip, and that it is "fundamentally reconstructive, and not destructive, in type." Every orthopaedic surgeon will at once recognize it as a fairly typical arthroplasty of the hip. The chief features of the operation are: (1) the free exposure of the hip by an antero-external flap; (2) the separation of the great trochanter, which is turned upwards with the muscles attached to it; (3) the modelling, rather than the cutting off, of the head of the femur; (4) the attempt to prevent the formation of new bone by the use of bone wax—a procedure that has been adopted by many surgeons in place of the flap of soft parts originally employed. Mr. Platt does not say whether he excises the capsule of the joint—a step which J. B. Murphy considered to be of the greatest importance. This operation differs from arthroplasty for bony ankylosis only in that the acetabulum does not need to be reconstructed as well as the head of the femur.

It is true that arthroplasty of the hip may be performed fairly rapidly, but there is no denying that it is a very severe operation, and I would take leave to doubt that it is "specially

suitable for older patients" with osteo-arthritis. One of our chief difficulties in treating osteo-arthritis of the hip is the fact that so many of the patients are just those in whom one would not care to undertake a severe major operation if it could be avoided.

Most surgeons have been disappointed with the functional results of arthroplasty of the hip. A lasting, stable, movable joint is the exception, while an ultimately stiff joint has been the rule. The degree of mobility depends very much on the amount of bone removed, and in many of the recorded successful cases the skiagrams have shown total absence of the head of the femur and sometimes of part of the neck as well—in fact, excision.

Now a straightforward excision of the hip—especially when there is no need to dissect away the synovial membrane, as in tuberculosis—is almost a minor operation as compared with arthroplasty, and if it will serve as well it is surely preferable. In the classical anterior operation an incision is made straight down to the joint in the interval between the sartorius and the tensor fasciae femoris. No muscles are divided. The capsule of the joint is opened and the head of the femur is dislocated and cut off with a chisel. The neck is returned to the joint, some stitches are put in the capsule, and then the skin wound is closed.

As judged by published statistics, the functional results of excision of the hip are bad. But nearly all these statistics have been obtained from the records of children who have been operated on for tuberculous disease of the hip. In many cases much more than the head of the femur has been removed—even the whole neck down to the great trochanter—and they have had no proper after-treatment.

The results of excision of the head of the femur (only) in non-tuberculous affections in adults, when the proper after-treatment is carried out, are in many cases excellent, and will, I believe, challenge comparison with the best results of arthroplasty. I now regard a simple straightforward excision as the operation of choice when one must operate for osteo-arthritis of the hip, and it is indicated also in those cases of chronic painful arthritis believed to be of infective origin.

My routine after-treatment is to put the limb in extreme abduction in plaster-of-Paris for two months. The plaster is then cut up as a splint, and the patient is measured for a walking calliper. During the next four to six weeks the limb is massaged and active and passive movements are practised. The calliper is then worn for six to twelve months. It is possible in this way to obtain a joint that is stable and yet movable and free from pain, with very little shortening of the limb.

I have been moved to write this somewhat lengthy criticism lest some of those who read Mr. Platt's paper should be led to think that excision of the head of the femur is an obsolete operation, and that the expression "excision of the head of the femur" is now synonymous with arthroplasty of the hip.—I am, etc.,

London, W.I., April 30th.

A. S. BLUNDELL BANKART.

PROSTATIC ENLARGEMENT.

SIR,—I am obliged to Professor Kenneth Walker for his courteous toleration of my criticism of his opinions. His remarks on the abuse of suprapubic prostatectomy are very opportune, and will surely meet with the approval of those who see many of the end-results of this operation. Most of the poor results are, in my opinion, due to failure to discriminate between the condition for which the operation was originally introduced, the so-called adenoma of the prostate, and those conditions where, in spite of the symptomatology, little or no enlargement of the prostate can be found clinically.

In the adenomatous enlargement the operation is so successful that its too frequent performance must be rare. I do not wish it to be deduced from this that I advocate removal of all such prostates, but the indications for prostatectomy raise a question too big to be dealt with in a letter. The number of cases in which a two-stage operation is necessary, while sometimes a mark of an insidious onset and progress, is more often a reflection upon the prolonged use of palliative measures, under which I include drugs, catheters, and sounds.

In cases of the prostatic bar, the small fibrous or atrophic prostate, the chronic inflammatory prostate, and malignant disease, suprapubic prostatectomy is seldom necessary, as equally beneficial results follow other procedures. Malignant disease is only rarely sufficiently limited to be removed by

operation, and radium therapy and diathermy give better results. The chronic inflammatory prostate is more often the consequence rather than the cause of the associated inflammatory changes in the urinary tract, and after its removal there is a tendency to sclerosis and stricture formation. Subsequent treatment by dilatation and local applications is necessary, the effect of which is equally satisfactory when no operation has been performed.

Forage is of value in cases where the obstruction is limited to the bladder neck, as in the prostatic bar, the small fibrous prostate, and the small hypertrophy of only the middle lobe, and is best carried out by diathermy applied by the Buerger or MacCarthy cysto-urethroscope. It is followed by marked improvement in some cases; in others it leaves much to be desired. I think there is still much to be learnt about the pathology of these cases, for some appear to be associated with an idiopathic atony of the bladder, others with over-action of the sphincter. In the adenomatous prostate the urethra is compressed laterally throughout its length, the obstruction is over a wide area, and its removal is difficult; the result of forage here is only temporary and cannot be compared to that of prostatectomy, which is always the operation of choice in the adenomatous prostate.—I am, etc.,
Cardiff, April 15th. T. E. HAMMOND.

BOVINE ACHONDROPLASIA.

SIR,—The monstrous calf of the Dexter breed of cattle exhibits the classical features of achondroplasia as found in the human. Examination of the endocrine glands of these stillborn calves has shown that in all (nine) cases the adrenal is strikingly abnormal, in that areas of cartilage are present scattered irregularly throughout the gland. The thyroid is functional—the extract producing the typical ageing effect on growing tadpoles; the pituitary normal.

This association of abnormal cartilage-bone growth and cartilage in the adrenal is remarkable, and I write to ask if any similar observation has been made in the case of the human.—I am, etc.,

F. A. E. CREW, M.D., D.Sc.,
Animal Breeding Research Department,
The University, Edinburgh,
April 24th. Director.

EVIDENCE OF PANCREATIC DISORDER IN RICKETS.

SIR,—In his paper, "Evidence of pancreatic disorder in rickets," in the JOURNAL of April 1st, Mr. E. C. Dodds states that in cases of "acute rickets" he invariably finds a greatly increased diastase index of the urine and an average of about 75 per cent. of fat in the faeces. It is, perhaps, not very clear what Mr. Dodds means by "acute" rickets. The disease only commences with the utmost rarity after the eighteenth month, and it is unusual to see active rickets after two and a half years. And yet six out of the seventeen cases reported were between three and five years of age, and only four were under eighteen months.

I estimated the fat in the faeces of three cases of active rickets, aged two years and four months, one year and nine months, and eight months, and found only 11, 27, and 50 per cent. respectively. (The last case was an infant fed on cow's milk.) The diastase index of the case with 27 per cent. of fat in the faeces was 20. These three cases show that Mr. Dodds's deductions cannot be true for every case of rickets.

It would be interesting to know whether the cases reported were having cod-liver oil and malt as part of their treatment.—I am, etc.,

London, April 28th.

J. V. C. BRAITHWAITE.

THE COMPLEMENT-FIXATION TEST FOR THE EXCLUSION OF PULMONARY TUBERCULOSIS.

SIR,—In Drs. Pnuch and Gosse's article on complement fixation in the exclusion of active tuberculosis (April 1st) it would have added to the interest of the article if they had been able to record the results of parallel tests of the dermic reaction to tuberculous inoculation, especially in the cases which reacted negatively to the derivation of complement test. I am aware that little or no value attaches to a positive dermic reaction, but logically the latter reaction ought, I suppose, to prove negative in the cases that replied negatively to the complement test. Possibly these observers had reasons of their own for not invoking the confirmation (or otherwise) to be obtained by the dermic test.—I am, etc.,

Algiers, April 18th.

ALFRED S. GIBB, M.D.

REDUCTION OF MEDICAL FEES.

SIR,—With regard to the letters on the reduction of medical fees, I do not see why any single member of the profession should try to influence his brethren to act collectively in reducing fees. If any member feels that his skill in the practice of his profession is not of a high enough standard to retain his patients at the fees he has been charging lately, then it is his own concern alone as to whether he should reduce those fees. The only other reason I know of for a reduction would be that he cannot get his accounts paid owing to the financial standing of his patients; but the question he would have to ask himself then would be, Would the accounts be better paid when the reductions were made? If a suggestion either to raise or reduce fees is made by the British Medical Association it need not be looked on as more than a suggestion.—I am, etc.,

Manchester, April 27th.

MARTIN J. CHEVERS.

THE INSURANCE ACT AND THE PUBLIC HEALTH.

SIR,—Twice has my Division sent to the Annual Representative Meeting a motion urging an inquiry as to the effect of the Insurance Act on the standard of living of the poor. It was based immediately on the fluctuations in our tuberculosis mortality—surely a fair test—foreseen in 1911 for 1915, and again in 1916 for 1918 and succeeding years. The major premiss need not be laboured now as it had to be ten and fifteen years back. To one who was the first to point out in the medical (and as I believe in the lay) press the relation between that mortality and the real wage rate, it cannot but be gratifying to see its widening acceptance in and out of Parliament. To establish the truth of the relation a fall was necessary in the last year of the war and the succeeding years. But the period of remission is drawing to a close. Others than I have told me that they have my experience—namely, that there are more cases to-day, certainly new or recrudescant or suspicious, than for many years past.

If the relation be a fact (and it is but common sense to believe so), it remains to ask if the Act lowers real wages. Only a child or an extremist politician will question that. Disguise it in what jargon you may, it is a tax on production. Economically the only unequivocal gainers are the "employed" children of the well-to-do, the great firms which used to pay full wages during sickness, or the powerful firms which can recoup themselves by raised prices for increased outlay. For all other classes there must be compensating disadvantages, the greatest for the poorest; the only question is how great.

The theory that by administrative benefits during sickness, involving an increase of poverty both in sickness and in health, a disease which flourishes on poverty can be prevented, is demonstrably false. But it is that which we are bidden to corroborate, it is that which we do corroborate if we tacitly acquiesce. To plead ignorance of economics (and our ignorance, as a profession, is abysmal) so as to shirk inquiry is no answer; nay, confessed ignorance is an added plea for inquiry. The whole question is fundamentally, as well as ostensibly, economic. If so, confessing ignorance, refuse to inquire: if it turns out that the effects of the Act, passed in 1915, have only been overlaid from 1918 to 1922 (about 1918 there can be no question): we are more bloodguilty than the politicians who honestly believe in their own knowledge.

The whole question is really to be reopened at Glasgow; for you cannot dissociate the State or municipal hospital from the Insurance Act. If the Act is right, then the State hospital is even more right; if the State hospital is wrong, then the Act is wrong. Under this bastard system, the result of the illicit intercourse of socialism and capitalism, both must be wrong, because its inevitable result is, *ceteris paribus*, the accumulation of great wealth in the hands of the few to the impoverishment of the many.

In Scotland manly independence is still a virtue, and sponging on others still is often considered a disgrace, and we may have a chance for discussion there. May I appeal to men who sympathize with these views to urge their Divisions to consider the underlying principle at stake? If you have admitted the obligation on the State to ensure primary treatment you must admit it also for advanced treatment. The principle of the State hospital is affirmed in the Insurance Act; if, as so affirmed, it is, in the teeth of the evidence, allowed to be acquitted by default, we are for the future debarred from criticism of any extension of that principle.—I am, etc.,

Rayleigh, Essex, April 23rd.

B. G. M. BASKETT.

THE ROUTINE OF OPERATIONS FOR TONSILS AND ADENOIDS.

SIR,—I have been asked to write to you in regard to the operative treatment of adenoids and enlarged tonsils, to which special reference is made in the BRITISH MEDICAL JOURNAL for April 1st (p. 527) and to inform you of the arrangements obtaining under the Education Authority of Glasgow.

Most of the cases recommended for operation are already under observation and treatment for ear disease by one of the authority's part-time aurists; some have been seen once only by the aurist; a few are cases obviously requiring treatment and recommended by one of the full-time school medical officers for operation, and in no such case has the operating surgeon (who is always one "with special experience of diseases of the nose, throat, and ear") considered operation unnecessary. The anaesthetic used is generally ethyl chloride.

All the children are examined at one of the centres as to their general fitness for operation and freedom from infectious disease on the morning before admission to hospital. They are admitted to the authority's hospital (ten beds) that evening, and the operation is performed about 9.30 next morning; all are kept in bed until the day following operation, when they are discharged from hospital if fit. In a few cases it has been necessary to keep the children one or two nights longer in hospital. The children are visited at their homes by one of the nurses until fit to return to school; the parents being instructed as to the after-care of the case; and notice is sent to the school in order that breathing through the nose may be encouraged and the child's progress observed.—I am, etc.,

ERNEST T. ROBERTS,

Principal Medical Officer.

Glasgow, April 26th.

Obituary.

EDWARD HENRY TAYLOR, M.D., M.Ch., F.R.C.S.I.,

President of the Royal College of Surgeons in Ireland; Regius Professor of Surgery, Trinity College, Dublin.

We regret to announce the death of Mr. Edward Taylor, President of the Royal College of Surgeons, Ireland, which occurred at his residence, 77, Merrion Square, Dublin. He was one of the most distinguished surgeons in Ireland.

Edward Henry Taylor was the eldest son of Mr. Wentworth Taylor, of Tinahely, co. Wicklow. He was educated at Trinity College, where he won the senior scholarship in anatomy, physiology, and histology, and qualified in 1890. Soon afterwards he won the surgical travelling prize and proceeded to Vienna, where he studied under Professor von Eiselsberg, the famous head of the surgical clinic and successor to the great von Billroth. On his return to Dublin Mr. Taylor was appointed assistant surgeon to Sir Patrick Dun's Hospital and lecturer in applied anatomy to Trinity College. Subsequently he acted as anatomical examiner in association with the late Professor D. J. Cunningham. Some few years later he was appointed surgeon to Sir Patrick Dun's Hospital. When the late Professor Edward Bennett was unable, owing to failing health, to discharge his duties as Professor of Surgery in Trinity College, Mr. Taylor was appointed to act as his deputy, and on Professor Bennett's death was selected by the Provost and Senior Fellows as his successor. This post he held for twelve years. Upon the death of Sir Charles Ball in 1916 Mr. Taylor succeeded to the Regius Professorship of Surgery.

He obtained the Fellowship of the Royal College of Surgeons in 1896 and was elected President in 1921. He wrote on many subjects of surgical interest and published well-known textbooks dealing with applied anatomy and operative surgery. He was the author of a treatise, *Applied Anatomy: Medical, Surgical, and Gynaecological*. His surgical writings included: "Some Researches in Cerebro-Cranial Topography by means of Röntgen Photography" (with W. S. Haughton); "Suprapubic Prostatectomy—the Aim and Scope of the Operation"; "Case of Cystic Tumour of the Brain, of doubtful origin, successfully treated by operation"; "New Methods of Herniotomy (Inguinal and Femoral)"; "Treatment of Acute Peritonitis"; "Operative Treatment of Rectal Cancer"; and other papers.

Mr. Edward Taylor, in addition to a very active professional career, found time for many agricultural pursuits, and was a successful breeder of shorthorn cattle, with which class he was a frequent prizewinner in the principal Irish shows.

Sir W. I. DE C. WHEELER, Vice-President, Royal College of Surgeons in Ireland, in adjourning the meeting of the Surgical Section of the Royal Academy of Medicine on April 28th, said:

The Surgical Section of the Royal Academy of Medicine in Ireland meets to-night under the shadow of Mr. Edward Taylor's death. He was President of the Section and President of the College in which we meet. He himself, I am sure, would have wished us to proceed with the business before us, for the progress of surgery was near to his heart, and he knew that the published transactions of this Section did much towards maintaining the reputation of the Dublin school in Great Britain and abroad. None of us, however, will feel disposed to proceed to ordinary business on the eve of his funeral. Our minds are burdened with the loss we have suffered, and we are full of sympathy for the widow and family he has left behind.

The profession is indebted to Edward Taylor for the demonstration of one fundamental truth: he has shown that success and respect, and everything in professional life which can be considered worth while, can be obtained by taking the straight road. Success to him meant hard work and results conscientiously achieved for the good of the school, for the advance of science, and for the benefit of all. Success was his, and his efforts were crowned by recognition from Dublin University, from the College of Surgeons, and from the profession at large. Thus he became president of this college unopposed; he was selected to follow E. H. Bennett as professor of surgery; and later to succeed Sir Charles Ball as Regius Professor in the Medical School of Dublin University. He received the degree of Master of Surgery (*honoris causa*) as a final tribute from the school in which he was reared. His books on operative surgery and applied anatomy breathe infinite accuracy, perseverance, and truth, and deservedly won him a high reputation in foreign lands. By his writings much was done to lift Irish surgery into the first rank. It gave a thrill of pride when travelling to find Edward Taylor's name on the lips of the great contemporary surgeons and his works quoted by the writers of the day.

His long illness prevented his taking part, as President, in College affairs, unless for a few early months of office. It was during this time I became acquainted with the personal charm and indefinable qualities which accounted for his popularity amongst those with whom he freely moved. He was open-minded and just; if he was capable of injustice it was to himself, for he was pre-eminently modest. He stood for loyalty in friendship; in work he ranked co-operation high above checkmate, and vigorously assisted in every forward move. He had a quiet dignity which added weight to his words, and although he may have lacked some of the frills and flashes of genius he was one of those men who got things done. Apart from his large circle of friends, he was able to attract and stimulate the wider circle of those about him, and this was one of his most winning powers. Outstanding ability, real work, and honest effort brought their rewards. In addition to academic honours and general respect his qualities as a surgeon received public favour, and he enjoyed a large share of the practice of southern Ireland. The surgical torch in this academy has been dimmed for the moment, but this Section can do honour to a memory by using the flame into brightness and illuminating for others the path by which the late President found his way.

JOHN ADAMS, M.B.E., M.B., C.M. GLASG.

Formerly Chairman of the Scottish Committee of the British Medical Association.

It was with much regret that we announced last week the death of Dr. John Adams of Glasgow, which took place at his residence, 1, Queen's Crescent, on April 20th. Dr. Adams spent some years as a chemist before entering upon the study of medicine at Glasgow University, where he had a distinguished career as a student, was Cullen Medalist, and graduated M.B., C.M. with commendation in 1883. He served for a period as house-physician in the Western Infirmary, then entered on general practice in partnership with the late Dr. Suttie, and later developed an extensive practice on his own account. Early in his professional career he became interested in medical politics, in which later he took a prominent part. His work in connexion with the British Medical Association forms one long record of faithful service. He was from the outset a most loyal member, and in 1908 was elected a representative to the central body, where his constant interest and unbiased judgement received due recognition by his election to the Council of the Association, on which he served from 1912 to 1917. During his same period he was a member of the Insurance Acts Committee, while he also was appointed chairman of the Scottish Committee. It would be difficult to overestimate

the value of his work for the Association, and for his fellow practitioners in Scotland, at a time when enthusiasm was on the wane. He was called upon to perform these duties at a strenuous period in the history of the Association, and the frequent night journeys to London which these necessitated, combined with the exacting work of his practice, undoubtedly took their toll of his health, which broke down under the strain. He was thus compelled to relinquish this part of his public work. He, however, continued to interest himself in the local Medical and Dental Defence Association, in which he also had been a very active and enthusiastic member; for some years he was chairman of the general council of that body, and on relinquishing this post was appointed one of its vice-presidents.

During the war period Dr. John Adams served as a member of the Medical Service Emergency Committee for Scotland and of its Executive, and his valuable services there and in other departments of war work were recognized in the honour of membership of the Order of the British Empire which was conferred upon him. Perhaps, however, Dr. Adams appreciated more the kindly esteem of his fellow practitioners, who in token of his valuable and unremitting work on their behalf entertained him to a complimentary dinner. He married only about three years ago, and is survived by his widow.

Dr. ALFRED COX writes: There were few better known or better liked men than Dr. John Adams during his many years of activity in Association affairs, and his death is sad news to many of his old colleagues who looked forward to seeing him again at the forthcoming Glasgow meeting. His work on the Council, the Scottish Committee, the Insurance Acts Committee, and the Scottish War Emergency Committee at a time when the work of the two last-named bodies was particularly strenuous will not readily be forgotten; but what will remain longest in the minds of those who worked with him is the memory of a very attractive personality, with a gift for friendship and hospitality. His colleagues and constituents in Glasgow and the West of Scotland will remember with gratitude the work he did for them, not only in the Association but in many other ways, as, for example, on the Glasgow Insurance and Panel Committees. I have little doubt in my own mind that his sudden breakdown in 1917 was very largely attributable to the way in which he sacrificed himself for the men who trusted him. Nobody but one who has had a similar experience of central work for the Association carried on from a long distance can quite understand what Adams's work entailed in the way of sacrifice. But he thoroughly enjoyed it, and I know what a grief it was to him when he was compelled to give it up. In the last letter I had from him, in January, 1922, in reply to a Christmas greeting, he said he was in bed for most hours of the day. He went on to say:

"I have been living on trinitrine tablets, digitalis, etc., which have gradually pulled me together, and I am getting to feel decently fit again and hope soon to be up and about. The Glasgow visit of the British Medical Association is evidently being worked well, and a great many people are interested in making it a great success. I am extremely sorry that it is impossible for me to lend a helping hand."

Scotland has given the Association many loyal supporters, but none who better proved his devotion to its interests.

HUGH ERNEST FRASER, M.A., M.D.,

Medical Superintendent, Dundee Royal Infirmary.

We regret to announce the death, on April 20th, after a long illness, of Dr. Hugh E. Fraser, of Dundee Royal Infirmary. Dr. Fraser was born in Inverness, and received his medical education at the University of Edinburgh; he graduated M.A. in 1887, M.B., C.M. in 1891, and M.D. with commendation in 1897. In 1890 he acted as demonstrator in pathology under Professor Greenfield, and in 1892 became senior house-surgeon at Edinburgh Royal Maternity Hospital. Subsequently he continued his studies in Berlin, where he took special interest in hospital construction and management. After a short period as resident medical officer at the Northern Infirmary, Inverness, he was appointed one of the honorary staff there, but in 1897 he received the appointment of medical superintendent of Dundee Royal Infirmary. During his tenure of office the institution became the clinical school for the University of St. Andrews, and many important additions to the infirmary were carried out, including the Maternity Hospital, which is a branch of the Royal Infirmary

and stands within its grounds, and the six wards (120 beds) which are primarily intended for cancer patients; the cost of these additions was defrayed by Sir J. K. Caird. Dr. Fraser gained a high reputation as medical superintendent, and his services were much esteemed alike by the board of directors, the medical staff, and the patients. Dr. Fraser also held the post of honorary medical electrician to the infirmary, and he was the author of a number of contributions on the subject of medical electricity. Dr. Fraser was one of those who can give more than whole time to their own work and yet maintain an active interest in culture. He was president of the local branch of the Franco-Scottish Society, which he accompanied in its tour to France last year. He had been vice-president of the Dundee Branch of the British Medical Association. He was unmarried.

MAJOR-GENERAL GEORGE DOUGLAS HUNTER, C.B., C.M.G., D.S.O., R.A.M.C. (retired), who died at Cadbury, Yatton, Somerset, on April 18th, aged 61, was the second son of the late Brigade Surgeon George Yeates Hunter, Bombay Medical Service; he was educated at St. George's, and took the M.R.C.S. in 1883, and the L.S.A. in 1884. He entered the R.A.M.C. as surgeon in August, 1884, attained the rank of Colonel in 1913, and was temporary Surgeon-General while acting as Director of Medical Services in East Africa; he retired on December 26th, 1917. He had a very long list of war services, extending off and on over almost his whole career: Sudan, 1884-85, Nile column, medal with clasp, Khedive's bronze star; Sudan, 1885-86, operations of Frontier Field Force; Dongola campaign, 1896, mentioned in dispatches, *London Gazette*, November 3rd, 1896, D.S.O., Egyptian medal with two clasps; Nile, 1898, battle of Khartoum, dispatches, *London Gazette*, December 9th, 1898, medal, and clasps to Egyptian medal; war of 1914-18, dispatches four times, *London Gazette*, January 1st, 1916, June 20th, 1916, June 30th, 1916, and March 7th, 1918, medal and star, C.M.G. and C.B. He was seconded for service with the Egyptian army from June 9th, 1888, to January 7th, 1897, and again from February 2nd, 1905, to July 5th, 1908, as principal medical officer. From 1909 to 1913 he was commandant of the R.A.M.C. school of instruction. In the late war he was Director of Medical Services of the East African Expeditionary Force from December, 1915, to March, 1918. He married in 1895 Elfrida, daughter of the late T. W. U. Robinson, of Houghton-le-Spring, by whom he had one son and one daughter. Lieut.-Colonel G. Y. C. Hunter, Bengal Medical Service (retired), is his younger brother.

DR. MURDOCH MACKENZIE, of Stornoway, died on April 10th at the residence of his sister in Bradford, after several months of indifferent health. He received his medical education at Edinburgh University and medical school, and took the diplomas of L.R.C.P. and S.Ed. in 1883. Soon after graduation he commenced practice in Stornoway, and he held the posts of medical superintendent and honorary surgeon to Lewis Hospital, Admiralty surgeon and agent, medical referee to the Ministry of Pensions, surgeon to H.M. prison, parochial medical officer, medical officer of Lewis Sanatorium, and many other public appointments in Lewis. He was a Justice of the Peace for the counties of Ross and Cromarty. For many years he held a commission in the Territorial Force. At the time of his death he was Lieut.-Colonel, R.A.M.C., T.F., attached to the Ross-shire Mountain Battery, and he had been awarded the Volunteer Decoration. Dr. Mackenzie, who was an old member of the British Medical Association, enjoyed the high esteem of his professional colleagues in the western islands of Scotland. He was often called into consultation by the more isolated practitioners in the neighbouring islands, where a visit might require sometimes several days' absence.

We regret to record the death of Dr. J. DAWSON CRAWFORD, J.P., which took place at Swanley, Kent, on April 4th, at the age of 54. Dr. Dawson Crawford was born in co. Monaghan, and received his medical education at Trinity College, Dublin; he graduated B.A. in 1891, M.B., B.Ch. in 1893, and M.D. in 1902. He came to reside at Swanley nearly twenty-five years ago, and built up an extensive general practice there; he held several public appointments, and was a Justice of the Peace for the county of Kent. He had been chairman of the Swanley Unionist Association for some years, and supported many projects for the welfare of the district. He was an old member of the British Medical Association.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE election of a Professor of Pathology, to fill the vacancy caused by the death of Sir German Sims Woodhead, will take place on June 1st. The income of the professorship will be £1,200 per annum. Candidates are requested to communicate with the Vice-Chancellor by Thursday, May 25th.

The plan of examinations for medical and surgical degrees to be held this term has been issued. Part I (Surgery; Midwifery) of the Third M.B. examination will begin on Tuesday, June 13th; Part II (Principles and Practice of Physic; Pathology and Pharmacology) will begin on June 14th. The M.Ch. examination will begin on June 13th. The certificates of candidates, accompanied by their postal addresses, must be sent to the Registrar for Parts I and II of the Third M.B.; and for the M.Ch. examination, by Monday, May 15th.

The following medical degrees were conferred at a congregation held on April 28th:

M.D.—F. N. Sidobotham.
M.B., B.Ch.—J. A. B. Snell, W. B. A. Lewis.
M.B.—E. Donaldson.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examination indicated:

Diploma in Psychological Medicine (with special knowledge of Psychiatry).—Elizabeth Casson, P. J. Fahy, O. P. N. Fearon.

UNIVERSITY OF BRISTOL.

THE following candidates have been awarded honours in the recent Final M.B., Ch.B. examination:

FIRST-CLASS HONOURS.—M. Critchley, P. Phillips.
SECOND-CLASS HONOURS.—Phyllis Beames, Winifred G. Nott.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary Comitia of the Royal College of Physicians of London was held on Thursday, April 27th, at 5 p.m., the President, Sir Humphry Rolleston, K.C.B., being in the chair.

The following were elected to the Fellowship of the College, on the nomination of the Council:

Edwin Hyla Greves, M.D. Edin., Sir Sydney Russell-Wells, M.D. Lond., Even John Maclean, M.D. Edin., Arthur Herbert Hayes, R.A.M.C., Robert Alfred Bolam, O.B.E., M.D. Durh., William Henry Wynn, M.D. Lond., Charles Fagot Lapage, M.D. Manch., Edward Fretson Skinner, M.D. Camb., Owen Lambert Vaughan Simpkinson de Wesselow, M.B. Oxf., John George Porter Phillips, M.D. Lond., Harold Wordsworth Barber, M.B. Camb., Arthur Geoffrey Evans, M.D. Camb., Aldo Castellani, C.M.G., M.D. Florence; Henry Hallett Dale, C.B.E., M.D. Camb. (under By-law xli (b)).

The following candidates were admitted Members of the College:

John Ferguson Chambers, M.B. Melb., William Feldman, M.D. Lond., Hugh Gainsborough, M.B. Camb., Norman Hammond Hill, M.B. Lond., James Gordon Hislop, M.B. Melb., Hugh MacLennan, M.D. Aberd., Charles Titterton Maitland, M.D. Lond., William Gifford Wylie, M.D. Edin.

Licences to practise physic were granted, jointly with the Royal College of Surgeons, to the following 108 candidates who had passed the required examinations and conformed to the by-laws and regulations:

*Edith I. L. Abbott, S. Ackroyd, M. Ahmad, D. R. Ainsworth, Janet K. Aitken, Ruth M. Arkwright, W. F. Attwater, C. W. C. Bain, F. J. Benjamin, L. A. Bennett, H. C. Berlie, H. J. Bhatia, A. M. F. Browne, C. B. Byrd, A. W. Carleton, R. B. Chandrachud, A. J. Chiappa, R. W. Cockshut, Doris B. Collier, Gwendolen C. Cotton, W. L. S. Cox, D. I. Currie, J. G. D. Currie, R. L. Dugger, H. S. Davies, C. C. Elliott, W. C. Faulk, C. E. Fenton, A. C. Fernando, Kna D. Foster, Rowden M. Fry, M. Garfield, F. A. Gaydon, J. E. Ga.
Gibbs, *Dorothy Gibson, Irene M. Griffith, F. J. S. Hall, E. Hardy, B. Homa, A. D. Jones, H. B. Jones, T. E. Jones, B. Kest, J. Kindness, D. Krestin, W. Laing, K. W. Lupprian, D. C. McIntosh, D. W. McMacpherson, *Phyllis M. Manson, *Gladys Mathias, Y. Maximos, F. R. J. Miller, J. K. Milward, A. Muench, W. E. M. Mitchell, Olga M. Naylor, G. J. V. Nelken, R. W. Nichol, M. Nurick, C. P. Oliver, T. C. Oliver, *Hilda W. Page, C. V. Patrick, V. D. Pennfather, *Edith C. Phelps, E. D. Pradie, *Gladys R. Randall, H. Bast, *Sybil M. Rees, B. T. Richards, *Esther Richards, D. Robertson, A. E. Roche, Abd-El-Hakim Sabry, J. W. Sinclair, E. F. Smith, *Dulcie C. Staveley, G. H. T. Stovin, M. L. Sutcliffe, *Mary I. Symons, J. G. Tait, M. Theiler, D. C. Thomas, *Winifred A. M. Thompson, Nils F. Tilander, L. J. Timmins, Eileen M. Turner, K. L. Ward, *Hilda M. Whitfield, F. W. Wickers, H. S. Williams, *Muriel B. Williams, S. J. Woodall, L. S. Woolf, *Lia Young.

* Under the Medical Act, 1875.

Diplomas in Tropical Medicine and Hygiene were granted, jointly with the Royal College of Surgeons, to the following 24 candidates:

R. W. Cilento, C. Clyne, G. C. Dunham, J. J. B. Edmond, M. A. M. el-Kattan, B. Gale, G. Giglioli, W. H. Grace, Mary L. Griffiths, J. M. R. Hennessy, H. S. Hingston, H. C. V. Joy, J. B. Kirk, R. R. Lal, D. R. Mehta, E. A. Mills, M. S. H. Noddy, D. G. F. Moore, G. G. Naoleker, A. Noble, W. H. Pencock, A. R. Razik, C. A. Welch, T. G. Wynne.

The President announced that two gifts have been made to the College: (1) The President's chair, used when the College lectures were in Warwick Lane. This was presented by Dr. F. G. G.

Wallace, with a letter stating that it had been given to Mr. John Charles Hunter, who was Beckett of the College from 1823 to 1829. (2) A malacca with two small glass phials in the shaft, presented by Mrs. Fagg. These gifts were accepted, and the thanks of the College were accorded to the donors.

A communication was received from the Secretary of the National Association for the Prevention of Tuberculosis, dated April 11th, 1922, urging that tuberculosis be made the subject of special teaching in Medical Schools. This was referred to the Committee of Management.

Dr. Sidney Phillips moved for the second time: That By-law LVII be altered so as to read—"The accounts of the College shall be audited by the Finance Committee, with the assistance of a professional accountant. A copy of the audited accounts shall be supplied to the Censors Board." This was carried.

Sir Frederick Andrews was re-elected a Representative of the College upon the Lister Institute of Preventive Medicine.

After some formal College business the President closed the Committee.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

PROFESSOR HAROLD BURROWS'S two Hunterian lectures on "The results and treatment of gunshot wounds of the blood vessels" will be delivered in the theatre of the College, Lincoln's Inn Fields, at 5 p.m., on Wednesday and Thursday, May 10th and 11th. The first lecture will describe the varieties of injuries and their signs and symptoms; the second lecture will deal with treatment in general and the operative measures available.

The Services.

THE WAZIRISTAN CAMPAIGN.

THE dispatch of General Lord Rawlinson, Commander-in-Chief in India, on the operations of the Waziristan Force from May 8th, 1920, to March 31st, 1921, was issued as a supplement to the *London Gazette* of April 26th, 1922. The following is an extract regarding the medical services:

"Waziristan has an unenviable reputation for climate. The extremes of heat and cold, combined with the virulent malaria indigenous to the country, are conducive to a high sick rate.

"That the sick rate has not been higher is directly attributable to the care and forethought of the medical authorities. The medical units throughout the force are mobilized ones, yet they have been expanded and developed so that the sick and wounded receive treatment much in advance of that ordinarily procurable in field units."

The King of Italy has conferred the honour of Commander of the Order of the Crown of Italy upon Surgeon Rear Admiral A. G. Wilkey, C.B., in recognition of services rendered during the war.

Medical News.

THE Court of the University of Leeds has decided to confer the honorary degree of D.Sc. upon Sir C. S. Sherrington, President of the Royal Society and Professor of Physiology at Oxford; Sir Harold Stiles, Professor of Clinical Surgery in the University of Edinburgh; and Sir R. A. Gregory, F.R.A.S., editor of *Nature*.

THE first lecture of the course of eleven post-graduate lectures arranged by the Fellowship of Medicine and Post-Graduate Medical Association was given at the house of the Royal Society of Medicine by Sir Humphry Rolleston, K.C.B., on Monday last, when he dealt with the recent physiology of the liver and its application in practice. The second lecture, to be given on Tuesday next, will be the first of two on fractures, by Sir W. Arbuthnot Lane, Bt. The course will be continued until July 19th. The lectures are given at 5 p.m. The Fellowship has also arranged a course of practical lectures and demonstrations at the Children's Clinic, Western General Dispensary, Marylebone Road, N.W.1 (close to the Edgware Road Station of the Metropolitan Railway). They will be given at 4.45 p.m. on Mondays and Thursdays. The first four meetings of this course will be devoted to a consideration of gastro-intestinal affections in children; the first will be given on May 15th by Dr. Beroard Myers, and the second on May 18th by Dr. T. Jockes; the third and fourth by Dr. Myers on May 22nd and May 25th. On May 29th Dr. H. E. Archer will demonstrate the Wassermann reaction and speak on its importance in general practice, and on June 1st Dr. H. Adamson will give a practical demonstration of skin diseases in children. The fee for the course is one guinea; full particulars can be obtained from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, London, W.1.

A MEETING of the National Baby Week Council will be held at Carnegie House, 117, Piccadilly, W.1, on Tuesday, May 8th, at 3 p.m., with Dr. Eric Pritchard in the chair. An address on "Mortality in the First Month after Birth, and the Possibility of reducing it," will be given by Sir Arthur Newsholme, K.C.B., M.D., and an address on "The Milk Question" by Dr. Janet Lane-Claypon.

THE annual Congress of Ophthalmology of the United Kingdom will be held on May 11th, 12th, and 13th, under the presidency of Mr. J. Herbert Fisher. Papers will be read and discussions held in the house of the Royal Society of Medicine, 1, Wimpole Street, on the morning and the afternoon of May 11th, and the mornings of May 12th and 13th. On the afternoon of May 12th cases will be shown in the ophthalmic out-patient department of St. Bartholomew's Hospital, and pathological demonstrations of tuberculosis of the eye will be given at the house of the Royal Society of Medicine on the evening of May 12th. The business meeting of the society will be held at 5 p.m. on May 11th, and the annual dinner at the Langham Hotel on the same evening at 7.30.

OUR readers are acquainted with the work of the Vocal Therapy Society, which has formed a number of the shell-shock and neurasthenic ex-service patients into choirs known as "The King's Services Choirs." They are giving a massed choral concert to-day (Saturday, May 6th), at 3 p.m., at the Polytechnic Institute, Maurea Road, King's Road, Chelsea. Visitors will be welcomed.

THE North-East London Post-Graduate College, as already announced, will hold a special post-graduate course at the Prince of Wales's General Hospital, Tottenham, N.15, from May 15th to 27th inclusive. The course has been arranged in association with the Fellowship of Medicine and Post-Graduate Medical Association, and a syllabus has now been issued which is obtainable from the Dean. The fee for those who are not members of the Fellowship is £5 5s., or £3 3s. for either week. Those wishing to attend should send their names to the Dean by May 11th. In connexion with the course lectures will be given on several afternoons at 4.30; these are free to medical practitioners.

THE Medical Missions meeting in connexion with the two hundred and twenty-first anniversary of the Society for the Propagation of the Gospel in Foreign Parts was held at the Church House, Westminster, on April 26th, with Dr. J. Auriol Armitage in the chair. Addresses were given on the subject of foreign missions by Dr. A. F. Laws, of Ay-In Hospital, Korea, Dr. H. H. Weir, secretary of the Medical Missions Department of the Society, and Miss M. Taylor, of Tinnevely and Delhi.

THREE HUNDRED cases of typhus fever have recently occurred at Frankfurt on the Oder. All boats coming from Russia are now subjected to quarantine.

THE Board of Trade has appointed a committee, under the Safeguarding of Industries Act, Part II, to report on the importation of optical and other scientific instruments into this country from Germany. It is alleged by associations of manufacturers interested in optical, photographic, and drawing instruments that, by reason of depreciation of the value of German currency in relation to sterling, the prices charged for German goods are below those at which similar apparatus can profitably be manufactured in the United Kingdom.

A MEETING of the National Health Society, with the Duke of Devonshire in the chair, will be held at the house of the Royal Society of Medicine on Wednesday, May 10th, at 5 p.m., when the Princess Christian will present certificates to the society's successful students. Among the speakers on the occasion will be Sir Arthur Stanley, G.B.E., and Professor Kenwood, C.M.G.

THE annual meeting of the American Medical Association will be held this year at St. Louis from May 22nd to 26th.

DR. JOHN MACMILLAN, J.P., of Newburgh, Fife, has been presented by his friends with a number of valuable gifts in recognition of his twenty-five years' strenuous professional services in the north of Fife.

A DINNER in recognition of her twenty-five years' work in the United States Public Health Service was given, on April 20th, to Dr. Sara Josephine Baker, director of child hygiene in the New York Department of Health.

FORTY free clinics for mental disorders are now conducted throughout New York State. During the past year nearly 5,000 persons attended these clinics, an increase of 34 per cent. over the previous year; more than half of those patients had never been under the care of State hospitals.

DR. MURK JANSSEN of Leyden has received the Umberto I prize awarded every five years by the province of Bologna for the best work or discovery in orthopaedics. The previous recipients were Professor O. Vulpius in 1905, Professor W. Schulthess in 1910, and Dr. Vanghetti in 1915.

DURING May the Paris, Lyons, and Mediterranean Railway Co., W.1, will run a special carriage between Paris and Evian-les-Bains, attached to the 8.45 p.m. train from Paris (Gare de Lyon).

IN the week ending April 29th the number of deaths from influenza in the 105 great towns of England and Wales was 75, as compared with 93 in the previous week.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Docillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

SALINE TASTE.

DR. M. P. K. MEXON (Bradford) writes: If Dr. Begg's patient will give up tea or coffee completely for a few days and thereafter indulge in these beverages only sparingly—say two small cups of tea or coffee (weak) a day—she would get rid of the saline taste completely. I have experienced this myself. I consider the taste is due to the excretion of some active principle of these beverages on the gums.

TREATMENT OF PARALYSIS AGITANS.

"E." writes, in reply to a recent inquiry: In some cases—perhaps one out of four—the administration of hyoscine hydrobromide will greatly lessen the shaking. A dose of gr. 1/100 by mouth three times a day is necessary; gr. 1/120 rarely succeeds. The treatment, if successful, can be indefinitely continued. In other cases, parathyroid tablets, gr. 1/10 thrice a day, do great good.

INCOME TAX.

A. W. Q. has been asked by the local inspector of taxes for a statement as to the amount of the professional debts due to him at December 31st, 1921, although he has for some years been assessed on the basis of cash receipts.

* * Unless some special fact (as, for instance, the purchase of an additional practice) enters into the case we see no reason why the cash basis should be abandoned, as would seem to be the intention of the local inspector. This point was discussed with one of the senior officials at Somerset House some short time ago, and a reference to our note in that connexion (December 10th, 1921, p. 1001) may assist our correspondent.

"J. M. M." as an assistant with a fixed salary beginning his fourth year, wishes to know whether he can adopt a three years' average although the first year's remuneration was only for a period of about six months.

* * The ordinary rule is that the average must begin to operate as from the date when the remuneration begins to accrue. Unless there are some abnormal circumstances "J. M. M." will be liable to assessment for his first "paid" year on the income of that year itself. As regards subscriptions to the BRITISH MEDICAL JOURNAL and the purchase of medical books we are of opinion that these are allowable so far as is necessary to maintain the personal standard of professional efficiency.

"R. E. T.'s" private practice expenses exceeded his (first year's) receipts from that work, but he has been separately charged on the amount earned at casual employment at the Ministry of Pensions medical boards under Schedule E.

* * There is, we believe, no justification for putting the assessment under Schedule E instead of Schedule D, in view of the casual nature of the earnings, and for many years the Board of Inland Revenue has acquiesced in the practice of pooling miscellaneous fees from public or semi-public bodies with receipts from private practice. The position would be different if "R. E. T." held a substantial salaried position with a few casual private receipts.

LETTERS, NOTES, ETC.

THE CONFERENCE OF STAFFS OF HOSPITALS.

DR. G. C. GARRATT (Chichester) writes: Mr. Harman (April 22nd, p. 662) fails to meet any one of my objections, and it must by now be obvious, even to him, that they are entertained by a very large number of medical men. His quotation from the SUPPLEMENT is worthless as a reply, because it does not define the term "indigent." The policy of the Association defines an indigent person as one certified as unable to contribute in any way towards his maintenance and treatment. Let Mr. Harman, as a "reasonable man," now approach those "other reasonable men" who manage his hospital, and explain to them that a person who while in hospital can scrape together a penny a week; or who receives eggs, vegetables, or other assistance towards maintenance from home, is "too rich" to receive "free treatment" from a staff that insists on retaining the title "honorary" and rejects paupers. Then let him report in the JOURNAL their comments on the "fairness" and "justice" of this proposal "to all parties concerned." I note that the habit I have contracted of always endeavouring to look ahead before adopting a new policy likely to have serious consequences is distasteful to Mr. Harman. May I be permitted to hope that this attitude of mind is not universal among members of the Hospitals Committee, otherwise there will be a dangerous split in the ranks of the profession, followed by another debacle such as occurred in 1912.

TREATMENT OF CRAMP.

"M. D. EDIN." a retired medical man, writes that he has been ill for nearly two years with rheumatic gout, effusion in the knees and ankles, oedema of the lower legs, and is greatly troubled with attacks of cramp in the legs. He cannot sit or walk without pain, and is relieved only when lying down or asleep. Many drugs and diets have been tried, in addition to electricity, ionization baths at home and at Harrogate, auto-serum, auto-suggestion; massage after baths has always seemed to aggravate the symptoms. His general health is good, the rheumatic symptoms better, but the cramp is worse. He has had much professional advice without relief, and would be grateful for any further suggestions.

"FOLLOWING UP" IN V.D. CLINICS.

MR. C. HEYGATE VERNON, F.R.C.S.E., Clinical Assistant, Bourne-month V.D. Clinic, sends us the following statistics, with the permission of Dr. W. E. Facey, medical officer in charge of the clinic, to publish them. They refer to the period of sixteen months from October 23rd, 1920, to February 21st, 1922:

A printed circular enclosed in a plain envelope not marked "confidential" is posted to a patient who has been absent for a period over a month from the date when the next attendance was advised. In only two or three isolated cases apparently have domestic troubles ensued, the cause being that the letter was opened by a relative from motives of curiosity or because the patient was absent from home. In every case a new patient is told, when his name and address are registered, that the information will only be used in the event of it becoming necessary to communicate personally with him.

Altogether 550 letters were written to patients, with a result that 152 have resumed attendance. Of the letters which did not bear fruit, 65 were returned through the Dead Letter Office, or produced the report that the patient had left the district. Three were reported dead, and 19 wrote reporting transfer to another clinic or doctor. Of the 152 who resumed attendance, 77 were ultimately discharged as free from disease and 51 as attending and within measurable distance of a cure. That a second and even a third letter provides sufficient stimulus to cause resumption of treatment is borne out by the fact that 27 had two letters, 10 of whom have been cured, and 3 have had three letters, 1 being cured. Letters are written even to those whose attendance has ceased before the diagnosis is established, and of these 7 have been discharged as not suffering from venereal disease. Of the remaining 53 who were cured, 32 were men suffering from gonorrhoea.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 36, 37, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35.

THE following appointments of certifying factory surgeons are vacant: Warboys (Huntingdon), Muirkirk (Ayr).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page...	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive postal remittance letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

527. Syringomyelia.

KOOX (*Med. Journ. of South Africa*, February, 1922) reports an early case of syringomyelia on which it was possible to carry out a thorough *post-mortem* examination of the brain and spinal cord on account of the fact that the patient died of pneumonia whilst in hospital. The symptoms had been headache and pain in the left shoulder; all the bones of the left side of the face were thickened and he had almost lost the sight of the left eye, and breathing through the nose was difficult; there was dissociation of sensibility on the left arm, left side of the neck and left half of the face. At the necropsy the frontal, temporal-zygomatic, and maxillary bones were all thickened on the left side, and the various sinuses had disappeared and been replaced by solid bone. Microscopically the ependyma cells round the central canal were thickened, and in the upper dorsal segments the lesion extended into the left posterior horn. For a short distance the glia cell accumulation was found in the left posterior tract, and in the upper cervical segments and bulbus the same process could be traced in the ascending filii. The author is of the opinion that such a case as this throws light on the debated point as to whether the trophic changes which occur in syringomyelia are due to lesions of separate trophic nerves, or whether the trophic influence is a function of the nerve fibres and cells of motility and common sensibility. Since there were so few sensory lesions in the head, no clinical signs of affection of the cervical sympathetic, and the circulation appeared normal, and yet the trophic changes were so marked, the author concludes that these were due to lesion of the spinal filii, the same centre to which pain and thermic stimuli of the overlying skin are conducted. The fact that hyaline degeneration was present in the walls of the blood vessels of the cord in addition to glia proliferation lends support to the possibility that syringomyelia may be due to a chronic inflammation and not merely a congenital glia proliferation.

528. Thrombosis of the Aorta.

AUBERTIN (*Arch. de méd.*, December, 1921), who records two cases in men aged 51 and 45, in addition to 32 cases already published, states that thrombosis of the aorta is sometimes of embolic origin, the embolism following mitral stenosis (Charrier and Apert, Achard), ulcerative endocarditis with cardiac thrombosis (Hijelt), but much more frequently it is due to arteritis, either of the aorta itself or of the iliac or femoral, with extension of the clot to the bifurcation of the aorta. The arteritis was due to atheroma in most of the recorded cases, but was due to syphilis in the cases of Bell, Achard, and one of Aubertin's patients, and to typhoid fever in three of Frison's patients. It may also be caused by an adjacent arteritis, as in one of Aubertin's patients, the subject of hip disease. With a single exception which occurred in one of Aubertin's patients, in whom the thrombosis involved the arch of the aorta, the thrombosis was confined to the abdominal aorta, and never passed above the diaphragm. The condition may be absolutely latent and not be discovered until the autopsy; but, as a rule, pain is present, and is situated, not in the abdomen, but in the lower limbs, especially in the feet and calves. In most cases (18 out of 32) there is a bilateral and symmetrical gangrene of the lower limbs. The gangrene may be of slight extent, being limited to the feet and lower part of the legs, or involve the whole of the lower limbs and reach up to the lower part of the abdomen, as in one of Aubertin's cases. The gangrene does not, as a rule, reach the stage of mummification, but generally consists of a violet discoloration of the skin, associated with cutaneous anaesthesia and a difficulty in carrying out certain movements. The reflexes are lost. The gangrene appears simultaneously on both sides, or there may be an interval of one or two days between its appearance in the two limbs. The circulatory disturbance may be less marked and consist merely of chilling of the limb and a slight degree of cyanosis. Sometimes the clinical picture of intermittent claudication is produced. The relative frequency of paraplegia (in 7 out of 32 cases) justifies its being regarded as a symptom of aortic thrombosis. Recovery through establishment of a collateral circulation has occurred in two cases. When there is bilateral gangrene the diagnosis is possible in most cases, especially when gangrene appears on both sides simultaneously. When the gangrene is confined to one side the diagnosis is possible if a complete absence of pulsation is present on the "healthy"

side, provided this sign is present throughout the lower limb and the pulsation of the two femorals cannot be felt at the crural arch. Aubertin describes two methods of treatment which are only applicable in cases of aortic embolism of sudden onset in which an early diagnosis is possible. The first consists in immediate massage, which, by breaking up the clot, may confine the gangrene to one of the extremities, or even prevent it altogether. The second method is surgical treatment, which was tried in two cases by Bauer and Kojeczny. In one case immediate recovery took place, while in the other death occurred a few days later, but re-establishment of the circulation took place shortly after the operation.

529 Gas Oedema Complicating Typhoid Fever.

EKVALL (*Uppsala Läkareförenings Förhandlingar*, March 15th, 1922) points out that in the course of typhoid fever the blood is often infected with a variety of germs other than the typhoid bacillus. These germs usually invade the blood from the intestines during the stage of ulceration, and have hitherto been identified with the aerobic bacteria. Infection with anaerobic germs is commonly overlooked because cultures are seldom made under anaerobic conditions. The author records a case of typhoid fever in which the sudden appearance of gas phlegmon in the right thigh was followed by rapid extension of the area of crepitation, and by the patient's death in twelve hours. He has collected eighteen similar cases from the literature, showing that this complication of typhoid fever is not very rare. In some cases stimulants injected hypodermically have been suspected of being contaminated with gas-forming bacilli, and though the author does not dismiss this explanation as altogether unsatisfactory, he attaches more importance to auto-infection through ulcers in the intestinal tract. He points out that gas-forming bacilli are normally present in the intestines, and that the most rational prophylactic treatment would be to keep typhoid patients on a lactic acid diet, which would temporarily discourage the growth of gas-forming bacilli. With this object, buttermilk, or food to which lactic acid bacilli had been added, should be given. As in his case the disease began on the outer side of the right thigh, on which the patient had been lying continuously, he recommends shifting the patient from time to time so that no one part of the body shall become devitalized by pressure and thus favour metastatic infection.

530. Dementia Praecox.

SWOLFS (*Le Scalpel*, March 18th, 1922), lecturing on dementia praecox, complains of the great variety of the classification of the psychoses, of the different terminology in different nations, and of the great refinement of differentiation. Dementia praecox is like any other dementia as far as the dementia is concerned, but differs in the age at which it attacks its subjects (15 to 20 years, and mostly males). As a rule there is no hereditary history. The immediate exciting cause is often overwork of the brain. Onanism is more often an effect than a cause. Although there may be temporary improvement, as a rule it is incurable. The four chief modes of onset are: (1) a simple form, without delirium; (2) a delirious form; (3) a katatonic type, characterized by cataleptic attitudes, negativism, and verberation; and (4) a paranoiac type associated with ideas of grandeur and persecution. At the outset it may be confused with neurasthenia, but the course of the disease soon reveals the real condition. Swolfs accepts Desmeth's definition of dementia as the more or less complete and irremediable loss of the psychical faculties.

531. Epilepsy and Marriage.

PARIS and VERNET (*Revue Médicale de l'Est*, February 1st, 1922) discuss the question of marriage in epileptics. They decide that it depends on the family history, the patient's personal history and antecedents. If these are good and show no marked signs of nervous degeneracy, marriage may be allowed. A marked history of alcoholism is unfavourable. But if the man is sober and temperate and the stigmata of nervous degeneration are absent in him and his family, he may be allowed to marry; for epilepsy is not necessarily hereditary, although, as is well known, epilepsy may be substituted in the descendants by other forms of nervous want of equilibrium, not perhaps so disabling as epilepsy, but of importance from the social point of view. Out of 33 epileptics whose family history was known, 18 gave a history of alcoholism in the father.

432. Epilepsy following Skull Injuries: Possibility of Cure by Operation.

TILMANN (*Medizinische Klinik*, March 26th, 1922) states that epilepsy occurred in 10 per cent. of his cases of skull injuries in the war. It is not bone splinters or foreign bodies, but inflammatory and reparative processes around them, which cause epilepsy by affecting the brain cortex. The most important indications of these changes are obtained by lumbar puncture. In normal healing the results of lumbar puncture are normal. But in epileptic cases either increased pressure or increased percentage of albumin, or both, are revealed by lumbar puncture. All cases presenting increased pressure of cerebro-spinal fluid, or increased percentage of albumin in the same, are in danger of becoming epileptic. In traumatic epilepsy a localized area is affected—bone, subarachnoid space, or brain, usually all three. The good results of operation in lesions affecting the bone only are in favour of operation in all cases of traumatic epilepsy, immediately after the first fit; the best results are then obtained. When a fistula is present and the cause of suppuration cannot be removed, Tilmann opens the dura mater freely at the trephining. In the meninges one finds frequently obliteration of the subarachnoid space, thickening, cysts, localized or associated with adjacent brain foci. The best results are obtained by removal of the brain foci, opening of cysts, and removal of brain abscesses. Usually surgical treatment is late and the results are not brilliant. The mortality of trephining is 4.4 per cent.; in 41 per cent. no results follow; 38.2 per cent. are temporarily cured; 16.4 per cent. are considerably improved. In the military cases it is yet too early to estimate permanent results. In all cases of injury to the skull in which the results of lumbar puncture indicate the probability of chronic inflammatory or reparative processes there are prospects of good results through operation at the seat of the injury or at a spot localized by the clinical symptoms. The earlier the operation the better are the results.

433. Pleuro-pulmonary Fistulae.

ACCORDING to Professor BARD (*Ann. de Médecine*, January, 1922), pleuro-pulmonary fistulae are much commoner than is the consequence of artificial pneumothorax treatment. The simplest way of demonstrating this communication is to determine the intrapleural pressure with a water manometer in a thin glass tube and then to make the patient cough several times. Immediately after this the pressure falls several centimetres, but after a few minutes' quiet respiration the pressure regains its original level in two or three minutes. Pleuro-pulmonary fistula is frequently followed by effusion into the pleural cavity, which may be hard to detect by physical signs but can be diagnosed by the shadow revealed by x-rays. The low content in oxygen of the gas contained in the pleural cavity does not indicate, as has been maintained, that no fistula exists, for the pleural fluid alone rapidly absorbs oxygen and liberates carbon dioxide. Bard is of the opinion that the current view is incorrect that pulmonary perforation is attended by grave symptoms; this only applies to the perforations which accompany the breaking down of inflammatory lesions. Simple pleuro-pulmonary perforations are usually valvular in type and can be detected most easily by the test above described.

434. Facial Contracture of Central Origin.

NOICA (*Bull. et Mém. Soc. Méd. des Hôp. de Bucarest*, October 19th, 1921) remarks that though contracture of half of the face is fairly frequent as the result of peripheral facial paralysis, facial contracture of central origin caused by a lesion of the pyramidal tract is very rare. On superficial examination it is impossible to say whether the contracture is of peripheral or central origin, but if the patients are asked to show their teeth, open their mouth, close their eyes, whistle, or put their tongue out, it will be seen that in the patient with peripheral paralysis the affected side of the face becomes extremely distorted, whereas in the patient with central contracture the face on the affected side behaves like that of a normal person, except that as regards the execution of movements requiring the play of muscles on both sides the muscular action predominates on the healthy side. Another symptom of diagnostic value is the following: Each of the patients is made to squeeze a dynamometer, when it will be found that the patient with peripheral contracture will keep his face motionless, while the patient with central contracture has an increase of wrinkles on the affected side, on which a pleasant smile appears, the normal side remaining serious. Lastly, electrical examination is decisive. In contracture of central origin there is no reaction of degeneration, whereas this is the rule in peripheral contracture.

SURGERY.

435. Fracture and Dislocation of Cervical Vertebrae without Paralysis.

HARTSHORN (*Boston Med. and Surg. Journ.*, February 2nd, 1922) records a case of fracture of the second and third cervical vertebrae with anterior dislocation of the first, second, and third vertebrae, as the result of a railway accident. The patient, beyond some swelling locally, showed no signs of paralysis or sensory disturbance or other lesions. He was treated by rest in bed and slight extension applied to the head, no forcible extension being considered advisable. Six months later the patient reported with no paralysis or neuralgias, but marked stiffness of the neck. In discussing the case he points out that injuries of the cervical vertebrae are fatal in a large percentage of cases. The spinal canal in this region is larger than in other parts of the column, and so there is greater range of mobility for the cord. Hence the patient may escape death sometimes in injuries of this region. Two types of case may be considered—those with paralysis and those without paralysis. Injuries to the spinal cord may be classed as (1) concussion, perhaps with a temporary paralysis; (2) trauma, with haemorrhage and paralysis present in some muscles which gradually disappears; (3) injuries to the cord from bony fragments, with pressure symptoms or laceration of the cord; (4) pressure on the cord due to dislocation of the vertebrae without fracture; (5) fracture and dislocation without injury to the cord; (6) compression fracture of the vertebrae. Any of these lesions, if recovery takes place, may show a later stage with painful neuralgias due to pressure from scars and callus and actual deformities which have been called "Kummel's disease." The prognosis depends upon the degree of paralysis—if extensive, the outlook is poor; if not extensive, recovery is probable. Removal of bony fragments is always advisable, and if dislocation alone is present extension of a forcible character should be tried. A number of cases have been recorded of a successful result after reduction. The greatest care must be exercised and all unnecessary trauma avoided.

436. Osteitis Deformans.

LEWIN (*Journ. of Bone and Joint Surgery*, January, 1922) reports three cases of this disease. This condition was first described by Sir James Paget in 1876. Its origin is unknown, and it causes deformities chiefly in the skull and long bones. The average age of onset is 49½ years, and males are rather more frequently affected than females. Syphilis has been thought to be an exciting cause, but it is now shown that the Wassermann reaction is negative and antisyphilitic treatment is of no avail. The gross pathology consists in the deformities, the most common being an outward and forward bowing of the tibia. Later other long bones are affected, and the skull and clavicles increase in size. The cranium is composed of finely porous bone substance, with a thin inner and outer plate on bone. The diploë is lost. In the long bones the normal relation of compact and cancellous structure is destroyed. The condition appears to start as an osteomalacia, when the deformities occur; this disappears and is replaced by an osteo-sclerosis, when the cortex of the bone assumes a hardness typical of osteitis deformans. The onset of the condition is slow and starts with vague pains in the extremities. Then a gradual decrease in height is noticed, associated with the bony deformities; the head becomes flexed and the chin approaches the sternum, and there is a marked cervico-dorsal kyphosis. The patient assumes a resemblance to the anthropoid ape. The diagnosis in the late stage is easy. Earlier, x-rays show the bone changes, and in syphilis other signs will be present. Bone tumours again are shown by x-ray examination. In rickets the bone changes occur on the concave side; in Paget's disease on the convex side. The prognosis as to life is good. Death occurs from intercurrent affection or sarcomata in the bones. Treatment is of little avail; the best hope is offered by phosphorus internally. After fracture the broken bone appears to heal with normal rapidity and firmness.

437. Naevus of the Meninges.

GREIG (*Edinburgh Med. Journ.*, March, 1922) records the case of a male, aged 18 years, with a vascular meningeal tumour associated with that peculiar skin condition known as adenoma sebaceum. The patient had been subject to fits for fifteen years and had a right-sided hemiplegia for eleven years. The fits started with an aura, and then twitching commenced in the right hand and involved all the right side; consciousness was not lost. The boy was fairly intelligent and between the fits lay peacefully in bed. His face presented a symmetrical papular naevoid eruption over the nose and cheeks. At the operation an osteoplastic flap was

turned down to expose the left cortical motor area. The Rolandic area was seen to be covered by an enormous number of large veins forming a vascular tumour. As removal was impossible the whole area was under-run with catgut and the vessels ligatured. He made a satisfactory recovery. The hemiplegia improved, but did not pass off, and he had some power in the right arm and could walk with assistance. Subsequently, after nine years he began to act strangely and had to be removed to an institution for observation. The writer points out that the condition was congenital and was liable to increase in size; as it later did. The focal nature of the convulsions and the retention of consciousness were the points in favour of operation. The result was surprisingly satisfactory, there being freedom from fits, and he regained strength in the affected limbs. His life was prolonged for nine years, and during eight of these he was able satisfactorily to carry out useful duties. The association of the cutaneous condition, if it be regarded as a vascular one, with the meningeal venous angiectasis is interesting. Adenoma sebaceum is known to be more common among congenital mental defectives and is often associated with convulsions. This condition itself is practically always congenital.

438. The Treatment of Prostatic Hypertrophy.

CARISI (*Ref. Med.*, March 13th, 1922) points out that the full examination of the hypertrophied prostate is an elaborate process, and the selection of the best method of treatment not as simple as is sometimes said. The selection depends mainly on the condition of the patient and the course of the disease. The method of Bottini (either open or closed) and its modifications still find favour—for example, out of 435 cases Bottini records 92.4 per cent. functional improvements, 3.7 per cent. failures, and 3.7 per cent. deaths. It is credited with simplicity and ease of execution, with very little danger to the patient, and not requiring narcosis. The results of galvanocautery are not immediate; it takes three or four weeks for the scarring to heal. The operation is not, however, as simple as is said; haemorrhage, partial cure, and relapses are not uncommon. It is contraindicated in lesions of the kidney, in purulent cystitis, and where the detrusor muscle is inactive. It is useful in complete chronic retention, in young subjects where it is desired to maintain the sexual power, and in weak old men with circulatory trouble. The rectal route has been abandoned. As regards prostatectomy Giordano speaks favourably of the perineal route, especially where it is desired to interfere as little as possible with the sexual functions, and his statistics give a cure of about 50 per cent., with a mortality of 15 per cent. But the hypogastric route is now more commonly used. Remote complications, such as persistent urinary fistula and urethro-rectal fistula, occasionally occur. As regards sexual power after the Freyer operation, of 23 people aged about 60 years, 12 remained unchanged, 6 kept the power of erection but no ejaculation of semen, 1 who before operation was impotent recovered sexual power afterwards, and 4 became impotent after operation.

439. Treatment of Elephantiasis.

PIGNATTI (*La Chirurgia degli Organi di Movimento*, February, 1922) records a case of elephantiasis of the leg of a young woman, successfully treated by the Kondolèon method. This consists in the free removal of an elliptical section from each side of the leg, comprising not only the skin and subcutaneous tissue, but the deep aponeurosis, so as to establish free communication between the deep and superficial lymphatics. The incisions are sown up without drainage. In the case recorded, seeing that rest in bed and ordinary incisions only gave partial relief, the Kondolèon operation was performed some months later. Before treatment there was an average difference of 10 cm. between the right and left legs; after the first operation this difference was slightly reduced, but after the Kondolèon operation, except in the lower third of the thigh, where there was a difference of 6 cm., there was hardly any difference between the two limbs, and the patient had been able to get about and do her work as usual; when seen eighteen months after the second operation she remained in good condition. Photographs of the legs before and after treatment show the marked improvement. The elephantiasis seemed due to chronic venous obstruction.

440. Fracture of the Anterior Superior Spines.

JAULIN (*Journ. de radiol. et d'électrol.*, November, 1921), who records an illustrative case in a youth aged 18, states that fracture of the iliac spines is usually due to muscular effort. It may occur as a separation of the epiphyses in the child and adolescent up to the age of 16 or 17, when the epiphyses become firmly united to the bone. Emmert observed a case of fracture of the anterior superior iliac spine after a violent extension backwards of the trunk; and Reverdin published a similar case in a young man who made a violent effort to save himself from falling backwards. Tellier reported a case

in a man aged 60. Similar cases have also been seen in young racehorses. In Jaulin's case the patient felt a violent pain in both anterior superior iliac spines while running as fast as he could. Abnormal mobility and crepitation were found on examination of the right anterior superior iliac spine, while on the left side there were only swelling and tenderness. The patient was unable to walk without the help of two persons.

OBSTETRICS AND GYNAECOLOGY.

441. Treatment of Cervical Carcinoma.

ACCORDING TO SCHWEITZER (*Arch. f. Gynäk.*, 1921, cxiv) a primary mortality of 5.8 per cent. occurred in 281 cases of cervical carcinoma operated on at the Leipzig clinic during ten years by Zweifel's modification of Wertheim's hysterectomy. After the uterus has been widely freed from the remaining pelvic organs, with the exception of the vaginal cuff, three sutures are placed in the posterior portion of the vesical wall, their free ends being attached to the myometrium. After suture of the pelvic peritoneum and closure of the abdomen the vaginal portion of the operation is commenced: the uterus having been removed by cutting around the vaginal cuff, the latter is attached to the bladder with the sutures which were made to descend with the uterus. The abdomino-vaginal operation has the advantages that the bladder receives an attachment which facilitates micturition and is protected from extension of infection from the vaginal wound, and that the duration of the abdominal manipulations is shortened. It is claimed that its primary mortality is less than one-half that of the unmodified Wertheim operation, and that the ureter and other neighbouring structures are less frequently injured. In about 4 per cent. of cases Zweifel's operation is not feasible on account of difficulties of haemostasis, and it is unsuitable for cases in which there is a small senile vagina.

442. ADLER (*Wien. Klin. Woch.*, 1921, xxxiv), while conceding that operative treatment of cancer of the cervix has probably attained its maximum curative possibilities, still holds that easy operable cases should be operated on whether by the abdominal or vaginal method; the operation should be followed by radium and x-ray treatment. The vaginal operation has a lower primary mortality than the abdominal, being 3.5 per cent. during the last ten years in the Sebasta clinic, where five-year cures are 22 per cent., a similar figure to that attained in the Wertheim (Weibel) clinic. The chief therapeutic advances to be anticipated lie in successful combination of radium treatment, x-ray treatment, and operation. The writer has found five or six years' freedom from recurrence in 59 per cent. of cases subjected to prophylactic radium treatment four weeks after operation, as against 42 per cent. of those not so treated. In eight cases operated on from three to four years ago 30 to 35 mg. of radium were placed in the parametrium on each side and left there for five to eight hours; of these patients six are still living, whether with recurrences or not is not stated. Lately the writer has combined the operative and radium treatment with intensive x-ray applications during the eight to fourteen days following operation.

443. Indications for Radium Treatment of Myomata.

PETT-DUTAILLIS (*La Gynéc.*, January, 1922) agrees with many French observers in preferring radium to operative treatment for most cases of uterine myoma, and from personal observations is inclined to the view that radium therapy is permissible even in certain classes of myoma for which it has usually been conceded that surgical is the only treatment. In three cases of submucous myoma the writer has had after radium therapy results which were ultimately successful. He points out that the surgeon should remember and the patient be told that in cases of myoma encroaching into the uterine cavity radium applications are immediately followed by a prolonged increase of metrorrhagia. In his first case haemorrhage and pain continued for six weeks, but in the end ceased altogether; the second was cured after a temporary set-back at the end of four weeks; the third had to have the application repeated seven months later. Small doses are preferable, and at any rate if there is risk of an intrauterine application causing ulceration and therefore infection of the myoma vaginal application is advisable; it is admitted that if the tumour lends itself readily to enucleation this is the best course to adopt. A success is recorded also in radium treatment of large subperitoneal myomata, causing pressure symptoms, but not characterized clinically by excessive haemorrhage. It has been said that radium treatment is contraindicated in large myomata—for example, cases in which the uterine sound passes more than 15 cm.: the writer, however, has subjected to radium treatment an

obese dyspnoeic patient with a giant myoma giving rise to continuous metrorrhagia, with sequelae which so far have been satisfactory. He has also treated by radium application a patient, aged 40, suffering from retroverted pelvic myoma, giving rise to dysuria, constipation, and bilateral pain in the legs. In spite of the accepted opinion that myomata causing grave compression symptoms are beyond the scope of radium therapy, the patient has since been free from pain, haemorrhage, and dysuria for seventeen months, and the tumour has been arrested in its growth. Petit-Dutaillis controverts the view that there is no indication in cases of grave haemorrhage; this, he says, can always be stopped for a time by tamponage combined, if advisable, with curetting, and in such cases an immediate application of radium is followed by a definitive improvement of the symptoms. In cases of early carcinomatous metaplasia of a corporeal myoma, radium treatment alone may occasionally suffice; in more advanced cases it may be a useful adjuvant means, leading to an improvement in the patient's general condition, so that later she becomes better able to support operation. With regard to coincident adnexal complications, the writer concedes that acute inflammatory disease of the adnexa constitutes a formal contraindication to radium therapy, and, although Chéron has reported 171 chronic cases subjected to radium emanation he has himself hesitated to essay this; nevertheless he sees no barrier to it in cases where the adnexal inflammation may be regarded as extinct.

444. X-Ray Treatment of Fibroids.

LABEAU (*Gaz. hebdomadaire des Sci. méd. de Bordeaux*, February 19th, 1922) is of opinion that x-ray treatment of uterine fibroids is justifiable in the following circumstances only: (1) In women with small fibroids approaching the menopause in whom irradiation of the ovaries may produce a somewhat earlier menopause, after which retrogression of the tumour is the rule. Irradiation of the ovaries only should be undertaken, as irradiation of the fibroids may produce gangrenous lesions. Labeau deprecates irradiation of the ovaries in young persons whose sexual life is not yet over. (2) In patients on whom competent surgeons refuse to perform any operation on account of the state of their cardiovascular system, lungs, or general condition. Even in such cases benefit may be obtained by Apostoli's method, which Labeau has seen produce an arrest of the haemorrhage in a large number of cases, with so much general improvement that a successful operation could be carried out later.

PATHOLOGY.

445. A Synthetic Medium for Growing Tubercle Bacilli.

BORREL, COULON, BOEZ, and QUIMAUD (*C.R. Soc. Biologie*, February 18th, 1922), with a view to preparing a tuberculin free from peptones and other noxious products, state that they have succeeded in producing a synthetic medium for the culture of tubercle bacilli, which is constant in composition and of a suitable hydrogen-ion concentration. This medium is glycerinated, and contains carbohydrates, glucose, and mannite. As sources of nitrogen they use asparagine, ammonium carbonate, and sodium nitrate. The full formula, which seems to have been carefully elaborated, is as follows: acid potassium sulphate 0.25 gram, potassium monophosphate 0.5 gram, magnesium sulphate 0.25 gram, sodium nitrate 1 gram, ammonium carbonate 1 gram, asparagine 4.5 grams, glucose 5 grams, mannite 5 grams, glycerin 20 grams, potassium silicate 0.02 gram, iron sulphate 0.03 gram, distilled water 1 litre. Generally the hydrogen-ion concentration of such a mixture is 6.9—the most favourable for the growth of tubercle bacilli. If such a medium is inoculated, with a large surface, up to 1 gram of dried bacilli may be obtained in twenty days. The simplicity of composition of the culture medium, its constancy in results, the abundance of yield, and the possibility of obtaining by its use a tuberculin free from peptone, are noteworthy points. The further communication on the action of the tuberculin promised by the authors will be awaited with interest.

446. Pandey's Reaction for Differential Diagnosis between Meningitis and Meningismus.

PANDY'S reaction is performed as follows: In a small tube is placed 1 c.cm. of a 1 in 15 solution of phenol; to it is added a drop of the cerebro-spinal fluid to be examined. If the reaction is negative, no change takes place. If on the other hand it be positive, a bluish-white opacity is formed at the junction of the two liquids which sinks slowly to the bottom of the tube. It is seen best against a dark background. It is due to a precipitation of the albumins. WEIL, DUFOURT, and CHAHOVITCH (*C. R. Soc. Biologie*, February 25th, 1922)

have made use of this reaction in 18 cases of tuberculous meningitis, 2 of acute syphilitic meningitis of congenital origin, 1 of aseptic meningitis following stovaine anaesthesia, and 12 of meningismns. In no case other than one of true meningitis was a positive reaction obtained. The authors conclude that this is a highly serviceable test for differentiating functional from organic cases of meningeal disturbance. However this may be, these results must be accepted with caution, as no figures giving the number of times in which the reaction was positive are provided. In the absence of such data no opinion can be formed of the accuracy of their conclusions.

447. Observations on the Epinephrin Hydrochloride Test in Normal Individuals.

A SERIES of fifty normal individuals have been submitted by VAN WAGENEN (*Journ. of Indust. Hyg.*, March, 1922) to the epinephrin hydrochloride test introduced by Goetsch for the detection of hyperthyroidism. The test is dependent upon the fact that an increase in the active principle of the thyroid gland enhances the pressor action of epinephrin. For its performance the patient is required to lie quiet till the pulse rate, blood-pressure readings, and the respirations are constant for at least fifteen minutes. An injection of 0.5 c.cm. of adrenaline hydrochloride, 1 in 1,000 solution, is then given subcutaneously in the deltoid region. The pulse rate and blood pressure are taken every five minutes for the next hour, while all general symptoms, such as twitching of the platysma muscles, lachrymation, drowsiness, throbbing of the vessels, and a desire for micturition are carefully noted. A positive reaction consists in the rise in pulse rate of at least ten beats per minute, a rise of blood pressure of from 10 to 15 mm. Hg, together with a train of general symptoms and a local blanching of the skin at the point of injection. The results obtained in this series of normal students showed a positive reaction in 20 per cent. A study of the composite curves given in the text is sufficient to show that the distinction between a positive and a negative reaction is of a very arbitrary nature, and leads one to agree that the test is unlikely to be of value in cases in which careful clinical examination is unable to detect the usual signs of hyperthyroidism.

448. Differentiation of Pfeiffer's Bacillus.

CALDAROLA (*Annali d'Igiene*, January, 1922) says the true Pfeiffer's bacillus has the following characters: It is small (0.2 to 0.5 μ wide, and two or three times as long), it is immobile, and never forms spores or capsules, stains slightly, and is Gram-negative. It never causes septicaemia in animals, but is very toxic for the guinea-pig and rabbit, causing death by the action of its endotoxin. Inoculated into the brain it provokes an acute encephalitis fatal in four or five days. It has great affinity for the blood of pigeons, and none or very little for that of other animals. It ferments levulose, glucose, and maltose, but never decomposes arbutin. Organisms resembling Pfeiffer's bacillus will not conform to the above tests. The author says he has found two varieties of the true Pfeiffer bacillus, separated by serological criteria.

449. Pfeiffer's Bacillus and Influenza.

GOSIO and MISSIROLI (*Annali d'Igiene*, January, 1922), experimenting on animals with Pfeiffer's bacillus, found they could produce marked toxic symptoms (congestion, haemorrhage, and inflammation, especially in the lungs and lymphatic glands). All the various cultures possessed this pathogenic power, the determining element being the toxin of the bacterial cell. Fatal toxic symptoms also followed after eight to ten days from inoculation of the virus. In addition to the true Pfeiffer's bacillus other associated germs could be isolated from cases clinically described as influenza. The relation of Pfeiffer's bacillus to influenza still remains where it was. It is certainly sufficient to cause influenza, but not essential; for other organisms beside Pfeiffer's may open the way for what clinically is influenza. The hypothesis of provocative germs may explain the great infectiousness of the disease.

450. The Staining of Spirochaetes in Films.

PUENTE (*C. R. Soc. Biologie*, February 18th, 1922) gives the following method for the demonstration of spirochaetes in smear preparations: Fix the films in a mixture of formaline 2 parts, acetic acid 1 part, water 100 parts; complete the fixation in alcohol-ether. Heat in a test tube the following fluid, which has been recently filtered: 5 per cent. tannin 3 parts, 3 per cent. aniline hydrochloride 1 part; pour the boiling solution on the film and allow it to cool. Wash off in running water. Stain for a minute in boracic methylene-blue. The *Spirochaeta pallida* stains blue.

A Post-Graduate Lecture

ON

THE HUMORAL SYNDROME OF GOUT.

BY

PROFESSOR A. CHAUFFARD,
OF THE FACULTY OF MEDICINE OF PARIS.

In addressing you to-day I wish, in the first place, to thank you for the honour you do me in inviting me to take part in this conference. I see in it a promise of excellent relations of friendship and scientific intercourse which will unite our two countries more and more. But you must allow me to say also that it is not without hesitation and apprehension that I have made the choice of the subject with which I propose to deal. Am I not a trifle overbold to come and speak on gout here in England, where Sydenham wrote his immortal description of the acute attack of gout—a description always copied or imitated, but never equalled; where Bright taught us to recognize the gouty kidney; where Scudamoro and Gairdner wrote their classical dissertations; where Garrod inaugurated the scientific study of gout in demonstrating the pathogenic rôle of uric acid; and where so many eminent clinicians have since proclaimed the results of their investigations of this disease? My excuse is that in science nothing is final or perfected, and I shall have achieved my object if I awaken your interest in the new researches which for nearly two years I have conducted in my clinic at Saint-Antoine with my two co-workers, P. Brodin and A. Grigant.

It is necessary in every study of gout to return to Garrod; his book has not passed out of date, and is rich in information, in clinical experience, and in personal ideas. It was Garrod who first defined the humoral state in gout and recognized and proved its essential character—excess of uric acid in the serum. I am bound to recall the delicate test of the thread, with its crystalline deposits of uric acid. In spite of the fact that this technique seems not to be exact, since we cannot say that all the uric acid of the serum becomes deposited on the thread, Garrod was able to estimate the quantity found in 65 grams of serum, which in the five cases he quotes, when expressed in terms of 1,000 grams of serum, give the figures 50 mg., 125 mg., 30 mg., 175 mg., and 110 mg. A little farther on, for the blood of patients suffering from albuminuria or gout, he gives an average quantity of uric acid varying between 44 and 173 mg. per 1,000 grams. He is careful, however, to add that in all these analyses the quantity of uric acid obtained is undoubtedly less than the real figure. The limit of sensitiveness of the method is fixed at 24 mg. per 1,000 grams of serum.

It is very curious to note how Garrod's technique gave him results near to the figures which we obtain at present with improved methods. Results of absolutely the same order are obtained in both cases.

These ingenious researches of Garrod's are classical, and all clinicians have made use of the thread test. But this obviously imperfect process did not allow fresh progress, and whilst researches on the uric acid of the urine were multiplying we relied on the initial researches of Garrod for the uric acid of the blood. A new technique was necessary, and it came to us from America with the work of Folin and Denis, and the employment of the reagent phosphotungstic acid, which gives a blue colour with solutions of uric acid. The estimation, which was gravimetric in Garrod's method, has thus become colorimetric, and the researches of Lough, Fine, and Myers have brought new and interesting deductions.

According to the American technique the normal content of the serum in uric acid is estimated at 2 to 3 centigrams per 1,000 grams, rather a low figure on account of the solubility in water of the precipitate of urate of silver and magnesium, which diminishes the real figure of the uric acid of the serum.

In the technique modified by A. Grigant this cause of error no longer operates, and we believe ourselves to be able to say that the normal figure of uric acid per litre of the serum varies between 4 and 5 centigrams; hyperuricaemia commences above this.

Grigant's process estimates the uric acid without including the xanthin bases, and only alloxan and alloxanthin, derived from the immediate oxidation of uric acid, are included with this substance in the figures of the estimation. Setting out

in this way we were able to begin the study of gouty uricaemia, and the researches we have published¹ were carried out in the first place on thirteen gouty individuals, and we studied for each the level of the blood urica, of the uric acid, of the cholesterinaemia, and determined the uric secretion constant of Ambard, which is the most delicate means we possess for appreciating the degree of renal permeability. Our results are summarized in the following table.

TABLE I.

Diagnosis.	Blood Urea.	Ambard.	Uric Acid.	Cholesterolin.
Chronic gout ...	0.40	0.10	0.127	2.95
Acute gout ...	0.40	0.80	0.115	2.15
Chronic gout ...	0.33	0.10	0.122	2.25
" " ...	0.30	0.13	0.118	2.85
" " ...	0.33	0.03	0.118	2.07
" " ...	0.43	0.03	0.11	1.85
Acute gout ...	0.34	0.09	0.10	2.10
Chronic gout ...	0.35	0.13	0.10	1.65
" " ...	0.45	0.10	0.10	1.50
" " ...	0.45	8.12	0.09	2.15
" " ...	0.40	0.11	0.087	2.70
" " ...	0.40	0.11	0.078	1.80
" " ...	0.72	0.11	0.072	2.03

To this first series of cases I am able to add fourteen new cases, some observed at Contrexéville by M. Schneider, with estimations performed by Grigant, the others derived from my hospital or private practice. Here are the results:

TABLE II.

Diagnosis.	Uric Acid.	Cholesterolin.
Gout and uric acid lithiasis ...	0.10	2.67
Chronic gout ...	0.095	2.25
" " ...	0.035	2.13
" " ...	0.075	3.69
" " ...	0.069	3.25
Mild gout ...	0.055	1.85
" " ...	0.070	3.50
Biliary lithiasis and mild gout ...	0.05	2.70
Chronic gout ...	0.17	2.60
" " ...	0.10	1.83
" " ...	0.73	—
" " ...	0.11	1.80
" " ...	0.06	2.40
" " ...	0.07	1.98

The average for all these figures gives for 27 cases 0.094 of uric acid, and for 26 cases 2.25 of cholesterolin in the serum. On the other hand, in a case of juvenile hereditary gout studied during the crisis and immediately afterwards, we have found a lower series of figures—namely, 0.24 for urica, 0.023 for uric acid, and 0.82 for glycaemia. Only the cholesterinaemia was increased to 1.95, and the bilirubin of the serum was in excess. In this case Ambard's constant stood under the normal at 0.06, and perhaps the exaggerated permeability of the renal filter was the cause of the low figure for uric acid. Hyperuricaemia was not present, but the participation of the liver was evidenced by the high level of the cholesterinaemia and by the excess of biliary pigment in the serum.

Thus the hyperuricaemia, discovered by Garrod, is confirmed and made more precise by modern researches. But whence arises this excess of uric acid?—a very complex question, and one still beset with uncertainty. In the first place let us differentiate between endogenous and exogenous uric acid.

For the endogenous uric acid we must distinguish two sources. On the one hand there is a disturbance of nitrogenous metabolism—and this is the factor we know least

¹ One of a series of exchange lectures between the Faculty of Medicine of Paris and the University of London. Delivered at the Royal Society of Medicine, March 23rd, 1922.

about in spite of the number of researches which have been devoted to it. There seems no doubt that uric acid is derived from nucleo-proteins and purins of the tissues by a series of degradations, due probably to the action of proteolytic ferments, the uric acid, according to Lambing,² "representing in man the end-product of the metabolism of purins—that is to say, a waste product which the organism does not further simplify." But the endogenous origin of the purins in the gouty, and their nature and manner of variation, still remains a mystery—as, for example, in cases of early hereditary gout, where the exogenous cause plays no part.

On the other hand, there is a second cause of endogenous hyperuricaemia of which the frequency and significance are easily understood—namely, renal retention. We know by clinical experience how often the kidney is damaged in the gouty, not only as a contracted and sclerotic kidney, but almost from the commencement of the illness there may be a functional defect betrayed by the elevation of Ambard's constant, as in our cases. This is only a secondary effect in the morbid process; but it ought never to be lost sight of without clinical consideration of hyperuricaemia. The retention of uric acid may even precede the retention of urea, and we believe ourselves able to say with P. Brodin and A. Grigaut that the detection of the former constitutes the most delicate test of commencing renal hypo-permeability.

Probably side by side with renal retention we ought to give a place to tissue retention, the gouty depositing uric acid in the tissues in excess, and being able to liberate it and return it to the circulation under the influence, for example, of causes producing acute attacks. This process does not appear to me to participate except in special cases, and its importance is not comparable to the uric acid retention of renal origin.

With regard to exogenous uric acid, for a long time the results of clinical observation have borne witness, and all are aware of what a large share in the causation of gout is attributable to errors of diet, to food in excess, too protein in constitution, too rich in spices, and to alcoholic beverages, notably burgundy and champagne.

The determining factors of the hyperuricaemia of alimentary origin are probably to be attributed directly to the excess, together with the secondary modifications in the nutrition and metabolism of the tissues and hepatic activity dependent thereon.

But here arises a question which cannot be separated from this discussion—namely, the rôle of the liver in gouty hyperuricaemia. The clinicians have for a long time admitted the capital importance of the part played by the liver, and the work of Scudamore and of Garrod on gout, and of Murelison on the functional disturbances of the liver, had led to the supposition that the liver manufactured uric acid when, on account of illness, its urea-forming function failed. On the other hand, the physiologists admit that in mammals uric acid and purin bases are destroyed whilst passing through the liver by uric-acid-splitting ferments. We have turned to experiment, in order to elucidate this point, by taking samples from the portal and hepatic veins of dogs for the estimation of uric acid during digestion and under various dietetic régimes. The following table illustrates our results:

TABLE III.

No. of dogs.	Régime.	Blood.		Coefficient of retention in liver.
		Portal.	Hepatic.	
1.	Fasting.	gr. 0.087	gr. 0.007	0
2.	"	0.011	0.011	0
3.	"	0.015	0.015	0
4.	Milk	0.005	0.006	0
5.	Varied	0.007	0.003	0
6.	Brain	0.010	0.003	20
7.	Calf's sweetbread	0.0118	0.009	23
8.	Varied	0.034	0.025	27
9.	Calf's sweetbread	0.031	0.022	30
10.	Varied	0.018	0.011	29
11.	"	0.015	0.010	34
12.	Liver and spleen	0.014	0.007	47
13.	"	0.013	0.006	53

Studying the details of these experiments we see that five dogs received a varied diet, two were fed on calf's sweetbread, and two with liver and spleen. The results obtained were all similar, and in eight of the nine dogs the quantity of uric acid in the hepatic blood was markedly less than that of the portal vein. Once only was the hepatic content a trifle higher than the portal—9 mg. in place of 7.

The proportion of uric acid retained varied between a minimum limit of 20 per cent. and a maximum of 53 per cent., with an average of 33 per cent.

The variability experienced in the retention coefficient must be attributed to many and special causes for each case: differences in the anatomical and functional condition of the liver in dogs of varying kinds; different stages of digestion; the nature of the food given.

The two highest figures of retention—47 and 53 per cent.—were obtained in animals fed exclusively with liver and spleen, a diet rich in uric acid. On the other hand, in three dogs maintained in the fasting state for three days, with as much water as desired, the content in uric acid was exactly the same in the portal and hepatic blood. The same result was obtained in a dog fed on milk, a diet which contains only traces of uric acid. Thus in the dog during the digestive period a greater or less proportion of the uric acid substances brought by the portal vein is retained by the hepatic cells, the liver playing the part of a regulating organ, designed to prevent the passage of excess of uric acid into the blood during the very frequent variations of the human dietary. We are ignorant of the fate of the uric acid thus retained, and we can only suspect that there occur in the hepatic cells complex chemical transformations of which we know one—the formation of urea. It is very probable that the fabrication of urea, the "protéopexie" of F. Widal, and the uricolysis are only different episodes, fragmentary evidences of the manifold action of the liver on protein material, all the stages of which we are far from knowing completely. This uricolytic function is periodic and only exercised under special circumstances, and it is very striking to observe the failure of this retention action in dogs in the fasting state, when the liver, no longer exerting any digestive control, allows itself to be traversed like an inactive gland. A milk diet which only supplies to the liver minimal traces of uric acid, and which throws least work on the liver, consequently acts in the same way as fasting, and the difference in the uric acid content of afferent or efferent liver blood.

But it is a rule in general that the physiological function has its counterpart in the pathological, and that the disturbed function can be deduced from the normal. Thus it appears permissible to state, in spite of the fact that direct proof cannot be given, that in the hyperuricaemia of the gouty the arresting function of the liver may prove insufficient, being incapable of retaining uric acid brought from the alimentary canal, and we might find in this the physiological explanation of the capital importance of diet in the gouty. Thus would also be explained the connexion which clinical experience has so long demonstrated between disturbances of the general nutrition, of the nitrogenous and carbohydrate metabolism, and functional disorders or lesions of the hepatic gland.

The uricolytic insufficiency of the liver thus appears to me to be one of the most important factors in the causation of exogenous hyperuricaemia of alimentary origin, and perhaps it may be passed on by inheritance—a possibility which would enable us to understand these cases of early hereditary gout, cases which cannot be explained as due to the life of the individual, and which can only depend on the transmission of an inherited defect.

Doubtless this is only an hypothesis of which one can show no direct proof in gout, but, as we have seen, it finds support in experimental physiology and in the other unmistakable signs of hepatic origin such as the hypercholesterinaemia and the hyperbilirubinaemia. Does not the same apply to other pathogenic theories in which one reasons more by deduction and analogy than by direct experiment, which is so difficult to carry out in clinical practice?

What becomes of the uric acid stored up in the tissues of the gouty, and what is its ultimate fate?

A part is eliminated in the urine according to the general law of the concentrating power of the kidney which Ambard formulated. When once the kidney is injured in structure or function then the elimination of uric acid is affected and may not suffice for its task. Another part, by a process of vicarious elimination, is deposited in the diseased joints as sodium urate,

in the tophi, in the urate incrustations of slow atrophic nephritis, and these local deposits once formed are not capable of being moved; they remain in ineffaceable witness of gout.

In the blood the circulating uric acid is more accessible to our therapeutic resources, and it is this which we wish to influence by diet or by our remedial agencies. It is difficult to say exactly in what chemical form the circulating uric acid occurs, but it is probable that it is in a state of colloidal solution as sodium urate, and we shall see what is the interest of the question in relation to the pathology of the acute attack of gout.

Finally, it seems that in chronic gout there is a uric acid infiltration of the tissues which is capable of modification, particularly by spa treatment. Schneider, Bricout, and Grigaut² thus explain the curious facts they have observed at Contrexéville. The blood uric acid of the cases of gout treated at this station instead of diminishing actually increases, as if the excess of uric acid in the tissues was mobilized, liberated, and returned to the circulation by the lavage, and then gradually eliminated by the kidneys. One or two months later there is found a remarkable reduction in the hyperuricæmia.

In order to complete the study of the serological nitrogenous metabolism of the gouty we must add that the level of the blood urea is generally slightly raised, although not often passing the physiological limits; this is illustrated by the figures in Table I. This is all that can be said at present of the origin and fate of uric acid in the gouty, and if many of the details are still hypothetical or obscure, perhaps the outlines of the main processes can be distinctly discerned. It was interesting to study the uric acid content of the blood cells at the same time as the serum. With the assistance of P. Brodin and A. Grigaut⁴ we have attempted to carry out this investigation, although we recognize that many of the associated factors are but ill understood. The same holds for the blood cells as for the serum; we are still unaware in what form the uric acid exists, for the chemical combinations must be very complex and perhaps variable and of colloidal constitution. In the healthy individual and in patients suffering from various diseases the average level of cellular uric acid appears to be 20 to 25 cg. per 1,000, though not indicating any definite connexion with the figures for the uric acid of the serum. The inconstancy and variability of the figures obtained only permit us at present to assign to the cellular uric acid a value doubtful and of secondary importance. It is otherwise in the gouty, and in the five estimations which we have had the opportunity of practising in the course of chronic gout we have found the level of the uric acid markedly raised, giving an average of 36 cg. per 1,000—that is to say, almost double. The proportion is the same for the serum, with an average figure of 9 to 10 cg., as compared with the normal average of 4 to 5.

Patients with gout are thus suffering from a double hyperuricæmia, both in the cells and in the serum, and the two surcharges of uric acid seem to be associated and proportional. The cellular hyperuricæmia is probably only a particular localization of the more or less diffuse impregnation of the tissues in the gouty.

This question of the supposed presence of uric acid in the tissues helps to solve another problem—namely, that of the clinical diffusibility of uric acid. Since uric acid passes into the urine by way of the renal filter it is therefore diffusible; but little was known of the conditions under which this occurred. Our experiments, carried out with P. Brodin and A. Grigaut,⁵ have shown us that in ascitic and pleural effusions, uric acid, like urea, is found in the same proportions as in the blood. On the contrary, it only passes in minute traces or minimal quantities into the cerebro-spinal fluid, in marked distinction from urea. Similarly, in experiments conducted with artificial dialysis it is found that uric acid passes much more slowly than urea. The diffusibility of the two substances is not therefore absolutely the same, neither clinically nor experimentally.

It was supposed that the hyperuricæmia was the only modification of the blood serum in gout. In reality the humoral syndrome is more complex, and, working with P. Brodin and A. Grigaut, we have added a new element, hypercholesterinæmia. It will be sufficient to refer to Tables I and II to see that this is the rule, and in fact in 26 cases in which the cholesterolin has been estimated the average level of cholesterolinæmia is 2.25 grams, a figure considerably higher than the physiological average of about 1.70.

Undoubtedly this hypercholesterinæmia may be due, in part at least, to suprarenal origin, when the kidney is more

or less affected in its eliminating function or in its structure. But the hypercholesterinæmia may be an initial fact and precede the renal lesion, since, as is demonstrated in Table I, we have shown it to coincide with a normal or only slightly elevated Ambard's constant, and consequently with physiological kidney function. In view of numerous experiences of this kind there is no necessity to presuppose an increased production of suprarenal cholesterolin, and the hypercholesterinæmia seems to be of hepatic origin. This is confirmed by the fact that the albuminous coagulum obtained by the action of trichloroacetic acid on the serum often shows after some hours a blue coloration more or less well marked, a reaction which betrays excess of bilirubin in the serum.

This double evidence of hypercholesterinæmia and hyperbilirubinæmia discloses the injury inflicted on the hepatic functions in gout, and only verifies the special state of nictolytic insufficiency which we have described as the result of our comparative estimations of the uric acid in the portal and hepatic veins. And thus the capital rôle which the liver plays in the pathology of gout is confirmed.

On the other hand, in the course of our researches on hypercholesterinæmia, it seemed to us possible to evolve a law—the law of the local deposition of cholesterolin when the serum cholesterolin is increased in a definite and permanent fashion. In this way we have explained the pathogenesis of xanthelasma, of biliary lithiasis, and of the white plaques of the retina in patients with Bright's disease. Shall we find in the gouty a new confirmation of this law?

Note first of all that biliary lithiasis is far from rare in the course of gout—6 per cent. according to Bouchard—and this clinical affinity, which it is classical to emphasize, has only been explained up to the present by vague theories, such as Bouchard's hypothesis of retarded nutrition. On the other hand, it adapts itself very well to the theory of the origin of cholelithiasis from the hypercholesterinæmia, the theory which I have formulated. Hutchinson observed a case of xanthelasma on the eyelids in a patient suffering from chronic and hereditary gout; Dyce Duckworth reported on palpebral tophi very similar to xanthelasma in a case of gout, and in another case multiple tophi of the scrotum, the chemical and microscopical examination of which showed the presence of sodium urate and crystals of cholesterol. Loeper, in many cases of gouty hygroma, has demonstrated the presence of cholesterolin. What is lacking in these early records is the chemical estimation of cholesterolin and uric acid in the tissues or tophi examined, and, above all, the determination of cholesterolinæmia. One cannot interpret the source and significance of the deposition of cholesterolin without ascertaining the quantity of cholesterolin in the serum. We have therefore searched for the presence of cholesterolin in the unfortunately very rare tophi which it has been possible for us to examine. In three cases of gouty deposits in the helix we have only been able to carry out Liebermann's reaction on account of the small quantity of material we had at our disposal; it was strongly positive, almost of the same order of intensity as that obtained with the xanthomatos nodules. The murexide reaction was also positive in the case in which it could be carried out. In a case of tophus of the finger, removed for diagnostic purposes, from a young man of 22 suffering from hereditary gout, and showing typical acute attacks since the age of 13, the cholesterolin content of the fresh material expressed per 1,000 grams was 8.30 grams and for uric acid 2.90 grams. This case was also peculiar owing to the fact that the tophi of the finger had really undergone a fibrous change. I have published the clinical history and histology with J. Troisier.⁶

At the autopsy of a patient who died of acute uræmia following renal tuberculosis typical deposits of sodium urate were found at the level of the articular surfaces of the metacarpophalangeal joints, but no cholesterolin was present. In a case of tophus of the heel estimation gave the enormous figures of 85.80 grams per 1,000 of uric acid and 21.30 grams of cholesterolin. Cholesterolin therefore appears to be a constituent element of gouty tophi, and this new fact might have been suspected from clinical examination alone. Nothing is more dissimilar in appearance than the pulp of a tophus and the gouty incrustation of a joint. The articular deposit is white as snow, whilst the pulp of a tophus is yellowish, the colour of pale fresh butter. Even viewed through the skin this butter colour of the tophus is easily seen. Chemical analysis accounts for this difference of colour, showing pure sodium urate at the level of the joints and a mixture of sodium urate and cholesterolin in the tophi.

Thus in gout the liver contributes largely to the typical double adulteration of the serum, hyperuricæmia and hyper-

holosterinaemia, and the tophus is only the external reflection of the humoral syndrome. It seems as though the tophus represents an effort of liberation on the part of the organism, a local deposit assisting in the elimination from the circulation of the excess of uric acid and cholesterol.

In all that has preceded we have described gout in the static stage when compensation is complete; but what happens when it passes to the dynamic state as evidenced by an acute crisis? At the moment we can only reason by analogy, and we are reminded of the suddenness of onset of similar acute attacks of asthma, migraine, urticaria—all paroxysmal illnesses and allied to gout by certain clinical affinities.

Since the researches of Vidal, Abrami, and Lancoveseo we have come to look on these morbid crises as precipitated by a disturbance of the colloidal equilibrium, very similar to anaphylactic reactions, with special modification in the number and percentage of the leucocytes, of the blood pressure, and albuminoid content of the plasma. All these crises can cause local lesions such as the oedema of the skin in urticaria and eosinophilic excretion in asthma. I think that it is along these lines that we must search for the explanation of the acute crisis of gout. Perhaps in the first place, as suggested by the researches of M. P. Weil and Guillaumin,⁷ the uric acid is in the free state in the plasma, or the greater part at least, and in the combined state in the blood cells. Guillaumin's technique seems to permit this differentiation.

In whatever ill-defined and colloidal form it exists the excess of uric acid places the gouty in a state of unstable humoral equilibrium, which may at any time be imperilled or destroyed under the influence of divers disturbing causes—errors of diet, traumatism of joints, in particular of the great toe, by fatigue or an ill-fitting boot, dampness and cold; and the seasonal changes to which the gouty are so sensitive.

Every gouty patient is sensitive to some disturbing agent or other, and there are those who cannot take a glass of champagne or burgundy without their having almost immediately an attack of pain in the toe. To the general sensitiveness must be added a local sensitiveness which causes the inflammatory process to light up always at the same point, creating thus true centres of uric acid crystallization.

If the disturbance of the humoral equilibrium is sufficiently intense the acute attack of gout flares up, and we can look on it as a true local shock, comparable to the shock of a migraine crisis. Latent sensitiveness of the gouty, provocative cause, and sudden shock in the affected area—these are the three periods of the course of gout, and we can compare the third of these to the local serological shocks which reproduce true local anaphylactic reactions, recently studied by G. Bouché and A. Hustin.⁸

In both cases there appears an active local vascular dilatation—vascular or sympathetic phase, "vasotrophic shock" of Bouché and Hustin—to which is added the painful reaction of the sensitive nerves. But in the gouty the process is complicated by a specific local reaction, the deposition, or rather the local flocculation, of sodium urate in the region of the inflamed joint. Does there exist at the commencement of the attack the haemoclastic reaction so well described by Vidal and Abrami? We do not yet know, and it would be very interesting, although in practice very difficult, to investigate the point.

However that may be, if this explanation of an attack of gout be accepted we are led to consider the uric acid present in excess in the serum of the gouty as a potential exciting cause, capable under the action of the provocative agent of determining a local and elective shock with urate flocculation; a process of this kind recalls the curious experiments of A. Lumière⁹ on barium sulphate, which in the molecular state of dispersion can be injected into the circulation without causing shock, whilst in the flocculated state it invariably gives rise to the symptoms of shock.

If one day the existence of this process could be demonstrated in gout we should have made a great step towards the explanation of the symptoms of an acute attack of gout. This will be the progress of to-morrow, the counterpart of the admirable work of Sydenham and of Garrod, who will always remain our guides in clinical gout, our undoubted masters in the study of this great humoral disease.

A British Medical Association Lecture

ON
PYELOGRAPHY.*BY
FRANK KIDD, M.Ch.CANTAB., F.R.C.S.ENG.

[With Special Plate.]

LITTLE time was lost after Roentgen had discovered the penetrating power of x rays in applying them to the detection of concretions in the urinary tract; but it was not until 1906 that it occurred to Voelcker and Liechtenberg to take advantage of the cystoscope and ureteric catheter so as to fill up the pelvis of the kidney with a fluid opaque to x rays and thereby obtain a photographic outline of the shape of the ureter and pelvis of the kidney. The paper published by these workers received scant notice for a considerable time, and it was not until some years later that their idea was taken up seriously by a number of workers in various countries and developed to its full possibilities. From 1910 onwards I worked at this subject extensively at the London Hospital, and in 1913 I published a full account of what I had been able to achieve on the clinical side, accompanying this with an account of experiments on sheep's kidneys, showing what happened to colloid suspensions when injected into the renal pelvis under varying degrees of pressure, and pointing out certain dangers and difficulties and how to avoid them.¹ I also produced evidence that the injection of such fluids under proper safeguards does no serious or permanent damage to the kidney.

During the last decade the method has been employed more and more until it has become recognized universally amongst urologists as an essential factor in their work. Pyelography was one of the chief subjects for discussion at the 1921 Congress of the Société Internationale d'Urologie held in Paris; at that Congress it was agreed that the method had come to stay and was one that had been developed to a high degree of safety in the hands of competent urologists. Dangers which were at first encountered by too strenuous workers have been gradually eliminated, and in the course of time improved injection fluids were discovered that cast deep shadows without irritating the kidney substance. At first various preparations of colloid silver were used, and later such substances as silver iodide, thorium nitrate, and potassium iodide, but none of these proved to be ideal. The silver preparations did not always cast a clear shadow, except in very strong suspensions, and the other substances sometimes gave rise to toxic symptoms. In 1918 Weld introduced sodium bromide, a 20 per cent. sterilized solution for the kidney and a 10 per cent. solution for the bladder. This though not an antiseptic is non-toxic and has the merit of casting a very distinct shadow. Nevertheless, it is sometimes very irritating if injected into a bladder the victim of a chronic cystitis, and in such cases I find it better to use a 10 per cent. suspension of colloid silver.

Pyelography enables us to study exactly the surgical anatomy of the kidneys, ureters, and bladder before proceeding to operation or treatment in a way which has been compared to the giving of opaque meals in the x-ray diagnosis of disorders of the alimentary tract. In practice it is found to yield a more accurate account as compared with the opaque meal or enema, which are frequently open to doubtful interpretations, the surgeon often failing to find what he has expected after a study of the opaque meal pictures. In dealing with the urinary tract it is seldom that we fail to find the exact condition revealed by the pyelo-radiogram or cystogram, though considerable experience is needed in interpretation of

* Delivered before a joint meeting of the Nottingham Medical Society and the Nottingham Division of the British Medical Association on March 15th, 1922.

the plates. Before the introduction of pyelography great strides had already been made with the introduction of the cystoscope and the ureteric catheter in the accurate diagnosis of the physiological and pathological state of the kidneys and bladder. Pyelography supplied a means of studying the surgical anatomy and completed the chain of evidence needed to secure a full diagnosis in any particular case. These methods taken together have made urinary surgery one of the most accurate lines of surgery at the present day. It is seldom that a urinary surgeon is obliged to cut down for exploratory purposes. If he has made a complete study of his case he should know exactly what he is cutting down for and know any variation in the anatomy that may be present in any particular case, so that he can go straight to the diseased point and correct it. Recently Carrell² and others have introduced a method wherein they pass a hollow needle into the perirenal fat and fill up this fat with carbon dioxide or oxygen. X-ray pictures taken under these conditions will often show up with extraordinary clearness, not only the outline of the kidneys but the suprarenal capsules as well. At first sight this might seem to be a very great advance, and as regards the suprarenal capsules it is undoubtedly a great advance, but as regards the kidneys I do not think the method adds very much to what we can already obtain without it. With a good modern x-ray outfit it is usually possible to show up a clear shadow of both kidneys if the patient has been properly prepared—not quite as dense, it is true, as by Carrell's method, but quite dense enough for practical purposes. If we wish to make a further study of the anatomy of the kidneys we can get more information by filling up the pelvis with sodium bromide through the ureteric catheter than we can by the method of Carrell. The former method shows up the anatomy of the ureter, pelvis, and calyces, and also the outline of the kidney, whereas the method of Carrell only gives the outline of the kidney. When in addition we consider that the passage of a ureteric catheter is probably less painful and less dangerous than passing a hollow needle and filling up the perirenal fat with gas, then we shall conclude that pyelography will continue to hold the field. Carrell's method will be chiefly reserved for a few exceptional cases where we suspect a tumour of the kidney, and where it is not possible to show this up by means of pyelography.

I will not detain you now with the history of the development of the method, but will content myself with stating clearly the technique which I at present employ as a result of eleven years' experience.

1. I consider it absolutely necessary to possess an x-ray plant of my own.

I often have need to apply this method to several patients in the course of a single day, and I soon found that it was quite impossible to arrange to take the patients round to a radiographer's house, get ready for cystoscopy, and clear up everything afterwards. The whole thing was time-consuming and wearing to a degree. I therefore resolved to put in my own x-ray apparatus, and I have never regretted it. I planned my x-ray room so that I could carry out cystoscopy without any waste of time on the same table on which I take my x-ray photographs. Catheterizing cystoscopes and ureteric catheters are ready at hand. In suitable cases, having taken ordinary x-ray plates, I proceed to catheterize the ureter, a process which does not take more than a few minutes, and I am then ready, with the patient on the table, to take as many further x-ray photographs as I require. I make use of a tungsten target tube, worked by a mercury interrupter and a 16-inch coil. I use an Albers-Schoenberg compressor, diaphragm, and air-pad, with the tube above and the film underneath the patient's back. The patient's legs are flexed so as to abolish the lumbar curve, and I employ on an average an exposure of two to three seconds, using up to 12 milliamperes and a 6-inch spark-gap. I use a double intensifying screen and duplitized films. I endeavour to take as short an exposure as possible. The essential point in taking kidney radiograms is to use tubes which are capable of giving a picture with a very short exposure. The patient is then able to hold his breath for the second or two during which exposure lasts, and there is no movement. If there is no movement then a clear shadow is thrown; if there is movement the kidney outline becomes obscured. Needless to say, the patient must have been properly prepared beforehand to ensure that the bowel is clear.

2. No anaesthetic should ever be used in taking pyelographic radiograms.

If the patient is under an anaesthetic it is possible to over-distend the pelvis of the kidney and so to damage the kidney. If he is conscious and the matter has been explained to him beforehand he will know at once if there is the slightest over-distension of the pelvis, as he will feel a sudden dull pain in the back of the loin. He is, therefore, asked to state at once if he notices any such pain. If he says he feels this pain, not only is the injection at once stopped but a little of the fluid is at once sucked out through the catheter before a pyelographic radiogram is taken. I cannot too strongly warn you against the use of an anaesthetic. This factor prevents those who are not very expert in the use of the cystoscope from employing the method. You need to have long practice in passing a cystoscope and passing ureteric catheters, especially in the male, if you are to avoid causing pain. It can only bring discredit on medicine when men try to employ methods in which they are not expert, and this is how damage gets done and methods fall into disrepute. The method is essentially one only to be carried out by the professed and trained urologist.

3. Only one kidney should be done at any one sitting.

At one time I used to try doing both kidneys, and in America it is, I believe, a common custom to do both kidneys at one sitting; but for a long time I have taught that it is not wise to pass ureteric catheters on both ureters at one sitting except under exceptional circumstances. It is far better, if you wish to get a picture of both kidneys, to bring the patient up again a few days later and do the other ureter and kidney. If you confine yourself to doing one kidney at a time you seldom, if ever, get rigors or any constitutional upset, whereas if you do both kidneys at a time you are liable to get vomiting and fever and the patient may have to go to bed for a day or two. For a long time now I have had no trouble of any serious kind after pyelography, and the patients are able to go home straight away. I always advise them to remain indoors and rest for the remainder of the day, but they are able to return to work the next day without any drawbacks.

4. I consider it is a mistake to employ too large a ureteric catheter.

This is sometimes done with the idea of blocking the ureter and preventing reflux, an idea that has been adopted by many authorities. In the average case I make use of a gum-elastic ureteric catheter with an olive end of a size No. 5½ Charrière. No. 6 is a little too large, No. 5 is a little too small, so that I select catheters of an intermediate size, picking them out by means of a gauge. Catheters with an olive tip pass more readily than those with a conical end. The catheters are placed in silk petticoats and are sterilized in a hot formalin vapour sterilizer specially made for me by the Genito-Urinary Manufacturing Company of London. By means of this sterilizer hot formalin vapour can be blown through the lumen of the catheters as well as around their surfaces. By sterilizing my catheters in this manner with meticulous care I have been able to avoid implanting infection in the kidney. If I employ a catheter for a tuberculous case I always destroy it afterwards and never use it again. In the case of a male patient I inject 2 drachms of a 5 per cent. solution of storaine into the urethra with a urethral syringe and hold it in place for ten minutes. I wash out the urethra with a pint of 1 in 4,000 mercury oxyganide solution, then pass a No. 9 English scale "Marshall" gum-elastic catheter, sterilized by boiling and lubricated with "lubalax," and empty the bladder. I wash the bladder clear and fill it with 8 oz. of a 1 in 4,000 mercury oxyganide solution. Then I pass the catheterizing cystoscope, sterilized in formalin vapour and armed with a catheter, catheterize the ureter, and leave the catheter *in situ*, removing the cystoscope. The cystoscope I am accustomed to employ is one specially made for me by the Genito-Urinary Manufacturing Company. It is nowhere larger than 24 Charrière, an exception to most catheterizing cystoscopes. It is specially rounded and smoothed off so that the lever when lowered does not project at all, and so that its passage is as easy and painless as that of the ordinary inspecting cystoscope. Very little attention has been paid to this point by most makers of cystoscopes, and this is one of the chief reasons

PYELOGRAPHY.

for difficulties experienced in passing the catheterizing cystoscopy on the conscious male. The cystoscopy is a single catheterizing cystoscopy. I never employ a double catheterizing cystoscopy, which is a clumsy and painful instrument and quite an unnecessary adjunct to the armamentarium of the urologist. I warn my younger readers to resist the blandishments of the instrument makers, and when starting to buy an outfit to refuse to purchase a double catheterizing cystoscopy. If by any chance I need to catheterize both ureters at a sitting, a practice I try to avoid, I remove the cystoscopy, rearm it, and pass it afresh, and so catheterize the other ureter. Having passed a catheter up the ureter selected for examination I place its end in a sterile glass test tube and collect a specimen of urine for bacteriological and cytological examination. In some cases little if any urine comes through at all for some minutes, in others a lot of pale urine comes away at once; but whatever happens depends entirely on the reflex effect the catheter has had upon the kidney. Usually it produces no effect, but it may produce a temporary oliguria or a temporary polyuria. It is quite a useless procedure to measure the amount of urine coming away, with the idea that this will give information as to whether the renal pelvis is a large one or a small one, and as to how much fluid has led to most of the accidents. Failure to appreciate this fact has led to many a picture. If you find a lot of pale clear fluid has come away in a short time and therefore think that you can inject your patients severe pain. This is the bed-rock difficulty in pyelography, in that you do not really know in any particular case how much fluid the pelvis will take. How this can be got over will appear in the sequel. The patient now lies on his back with the knees and hips bent so as to abolish the lumbar curve. The plate is placed behind the kidney area and the compressor and x-ray tube placed in position, the radiographer standing ready to give the exposure at the word of command. I now take my syringe and fill it with sterilized 20 per cent. sodium bromide. I instruct the patient to tell me at once if he feels the slightest dull ache or pain in the back of the loin, as this is the best guide to overdilatation. Then very slowly and with the utmost gentleness I begin to press the piston of the syringe and fill it with warmed fluid which it goes. It usually goes quite easily up to 6 c.cm. At this point I ask the patient if there is any pain; if not and if the piston is travelling easily, I usually let in one or two cubic centimetres more and then give the word for the exposure. Immediately I suck out the fluid from the kidney means of the syringe until I have sucked out the exact amount I have put in. This is a most important and helpful point. I then remove the syringe for a few minutes while the plate is being developed. When the plate has been developed I examine it, and if it shows that there is a velvety adequately filled I take no more pictures. If, on the other hand, there appears to be merely a faint and irregular shadow, this suggests that there is a hydronephrosis full of fluid which has diluted the sodium bromide solution until it no longer throws a dense shadow. When I know that, I can proceed to take a further picture. This time I fill up the pelvis first with 10 c.cm.; if no pain is felt I go up to 20 c.cm.; if no pain is felt I go up to 30 c.cm. (I seldom go beyond 30 c.cm.), and I then take another plate, and in this way get the pictures I show you to-night of congenital hydronephroses holding a large quantity of fluid. By thus taking the pictures in two stages of normal size, and it is a technique that I have worked out for myself and can recommend to others.

At one time I made use of a burette, letting in the fluid by pressure from a height. But I find that by using a syringe with a perfectly smooth and easy-running piston I get much better results, and the advantage of the syringe is that it also enables one to withdraw the fluid at once. I use a graduated all-quartz syringe made of infected I usually finish by washing out the kidney with 4 c.cm. of 5 per cent. colloidal silver,* but if not I do not wash the kidney out at all. Sodium bromide

is not in itself an antiseptic. I am therefore accustomed to add 1 c.cm. of a 1 in 1,000 mercury oxycyanide solution to every 9 c.cm. of 20 per cent. sodium bromide solution. This makes a weak antiseptic solution and one which in practice in my hands has been found to prevent infection of the kidney. I am indebted to Professor Leguen for the idea of adding the mercury oxycyanide, which acts as an additional safeguard.

Until recently one of the chief difficulties in this work was that when one used a syringe or burette one had to pass the fluid into the ureteric catheter through a very fine nozzle, finer than the internal lumen of the ureteric catheter; but for the last two years I have used a most ingenious piece of apparatus brought to my notice by the Genito-Urinary Manufacturing Company, which originated, I believe, from Paris. It consists of a small tube of rubber about an inch long. This, instead of having a cylindrical lumen, has a lumen consisting of two inverted cones. At each end the lumen is wide, but it narrows rapidly towards the centre of the tube, where it is quite small and less than the size of a No. 5 ureteric catheter. One end of the rubber tube is fitted on to the large nozzle of the syringe, the other end fits over the ureteric catheter, which is pushed up until it is firmly lodged in the narrow end of the cone. In this way fluid passes quite easily from syringe to ureteric catheter and back again. It has made just all the difference to me in case of manipulation.

A great deal has been made of the dangers of this method of examination. Abroad and in America one or two deaths have been reported, mostly in the early days, when great force was often used, so that kidneys were overdistended, and in one or two cases the pelvis was actually ruptured. One fatal case occurred recently in America, caused by poisoning from stale thorium nitrate. It is to be remembered that when drugs are injected under too great tension into the renal pelvis they may be absorbed into the lymphatics and even into the blood stream. It is, therefore, not wise to inject poisons into the renal pelvis, and it has lately been proved that stale thorium nitrate and potassium iodide are poisonous in large doses, but that sodium bromide and colloidal silver are not poisonous. I have never seen any fatal result, than the two latter, and I have never had to cut down on the kidney, as has been reported in the literature. Once or twice in my early days the patient has experienced considerable pain afterwards for some hours, has vomited, and has even had a little fever, accompanied by a rigor; but for the last two years, since I have used the improved technique described above, I have not seen any of these complications. Occasionally the patient suffers with a mild pain for a few minutes after the examination is finished, but this is quickly recovered from and yields readily to a dose of aspirin and rest in the recumbent position for half an hour. I do not meet even with this in one case in thirty, and it is never more than a mild and quickly passing phenomenon. If the patient does complain of slight renal pain after the injection it is an additional help in the diagnosis. He can then say the pain is exactly similar to the pain from which he has been suffering, or he can say it is quite different; in other words, an artificial renal pain has been created and enables the patient to distinguish between that and the usual pain of which he complains. Nevertheless I always ask the patient to drive home at once and go to bed for the rest of the day; or if he comes from a distance I persuade him to go into a nursing home for the night, though many reject the advice as they say they feel quite normal, and usually they are none the worse for it.

It is necessary by men who have trained themselves as experts in the use of the catheterizing cystoscopy and in the use of this method. It needs several years of careful practice before one can carry it out without producing pain and discomfort. It is also necessary to exercise wise judgement in selecting cases for this examination. This method is not to be used routinely for all renal cases, as is commonly done abroad; it is only to be used when it is impossible to make a full diagnosis without its use, and when all other methods have been previously tried. There is no doubt it has been used too extensively by certain workers as a routine method. If you can make a full and accurate diagnosis by simple methods, do not strain at a gnat and insist upon carrying out all the full paraphernalia of possible urological research. Thereby you may swallow a camel and your patient be worse rather than better.

* Five per cent. and 10 per cent. suspensions of colloidal silver are now prepared for me ready for use by the Crookes Laboratories, 22, Chenies Lane, W.C.1.

The lecturer then exhibited a series of lantern pictures illustrating a large number of pathological conditions. A selection has been made from these for publication as a Special Plate. The following notes are descriptive of the conditions shown.

Normal Kidney.

Fig. 1.—Showing the normal appearances of a normal kidney. Note the axis of the ureter running upwards to the upper portion of the pelvis, the necks of the calyces arranged in an upper, middle, and lower group (anterior and posterior), and the outline of the nipples of the pyramids opening into each calyx.

Congenital Abnormalities.

Figs. 2 and 5.—Showing a large solitary kidney on the left side, with the ureter on the right side ending blindly, or congenital absence of one kidney, by no means an uncommon phenomenon. The patient complained of aching in the left kidney, which was too heavy and had dropped considerably, and asked for its removal. Needless to say the request was refused and a belt brought relief.

Figs. 4 and 5.—Showing a case with four ureters opening into the bladder, all of which were catheterized. There is a double kidney on the left side and a double kidney on the right side with an early tumour of the lower pole. The patient complained of haematuria. The double kidney and tumour on the right side were removed.

Fig. 6.—Showing a horseshoe kidney. The upper part of the kidney is above the limits of the plate.

Fig. 7.—Showing an early hydronephrosis associated with a large aberrant renal artery pressing forwards on to an S-shaped kink of the ureter. The patient complained of renal colic. The artery was divided and a plastic operation performed on the kink. The kidney was saved, with complete relief of the symptoms.

Dilatation of Renal Pelvis associated with "Dietl's Crises."

A. Congenital Hydronephroses.—The lecturer said: I am not dealing now with large cystic hydronephroses of the kidney, which are quite obvious on abdominal palpation, and which are usually operated on for pain, bleeding, or infection, without any need for pyelo-radiography. I am dealing now with people who are born with congenital strictures, kinks, or valves in their ureters, or with abnormal renal arteries and bands pressing on their ureters, and who later on in life develop gradually increasing degrees of hydronephrosis. These patients complain of intermittent attacks of renal pain, and though it is sometimes possible during an attack of pain to feel a certain amount of enlargement of the kidney, yet as soon as the pain has passed the kidney returns to its normal size as it empties itself of any excess of fluid. These are the cases where the pyelo-radiogram comes as help to the diagnostician. Ordinary x-ray examination reveals no stone; a ureteric catheter is passed, and such pictures are obtained as are shown in the series of pyelo-radiograms. In these cases dilatation always falls primarily on the renal pelvis, and to a far greater extent in the early stages than on the substance of the kidney. The kidney substance is also thinned out, it is true, but the kidney lies like a cap on top of the dilated cystic pelvis—exactly the reverse to what usually happens when the pelvis is blocked by a small stone; then the pelvis shrinks on to the stone, and the kidney substance itself becomes a large distended cyst.

Fig. 8.—This shows the earliest degree of ballooning of the pelvis. The necks of the calyces are not yet distended at all. The patient complained of left renal colic.

Fig. 9.—This shows a higher degree of ballooning, and now a distinct dilatation or clubbing of the neck of the upper calyx can be seen. This illustrated another rule which I have observed—namely, that in hydronephrosis the stress always falls on the upper and lower calyces long before it falls upon and dilates the middle group of calyces. Attacks of pain. Kidney removed.

Fig. 10.—This shows a further stage in the development of hydronephrosis. The ureter is strictured at its junction with the pelvis and is inserted in a valve-like manner high up on the wall of the pelvis. There is advanced dilatation or clubbing of all the calyces. Attacks of pain. Kidney removed.

In none of these cases could the kidney be felt to be enlarged.

Fig. 11.—Showing the final stage of hydronephrosis. This was a large cystic kidney that could be felt on abdominal palpation. It took 40 c.cm. of fluid and even then was not nearly fully filled. It shows the extreme dilatation of the necks of the calyces. Attacks of pain. Kidney removed.

B. Movable Kidney.—Another form of dilatation of the pelvis of the kidney is seen in cases of movable kidney. A true hydronephrosis of the congenital type is never produced by mere excessive mobility of the kidney. Movable kidney can only produce a certain amount of ballooning and hollowing of the renal pelvis and calyces associated with

intermittent kinking of the ureter. The process can be followed in a series of pyelo-radiograms here shown.

Fig. 12.—The earliest degree is a kidney too low and too movable, with slight bending rather than a kink of the ureter, and with only the slightest ballooning. Fig. 13 shows an increase in the ballooning; and finally Figs. 14 and 15 exhibit a corkscrew-like kinking of the ureter.

Personally I always endeavour to avoid operating on movable kidneys. Those that are due to slack abdominal muscles can usually be relieved by abdominal exercises and strapping or a belt. Those that are due to a congenital narrow chest are often simply tender spots, the reflexes of an overwrought nervous system. If the nervous system can be rested and treated the kidney ceases to be tender. Nevertheless in this class of case patients are met with who get occasional attacks of most violent colic associated with anuria and followed by polyuria, "Dietl's crises." In between the crises they are often quite free from pain and do not complain of an aching kidney. It is in these we get pictures such as I show (Figs. 14 and 15) with marked kinking of the ureter and dropping of the kidney. I am willing to operate on such cases, as anchoring the kidney in its proper position does relieve them of these attacks of colic. Nevertheless the operation is a difficult one to perform satisfactorily. Far too often the surgeon cuts down and fixes the kidney either too low or else too high, and the condition is not relieved. In Fig. 16 I show an example of a kidney which has been fixed in too low a position by a surgeon. The colics were not relieved, and were so severe that I had finally to remove the kidney.

C. Sometimes inflammatory strictures of the ureter arise either from long-continued infection of the kidney or from the previous passage of a stone. In these cases there is usually an associated fibrotic thickening of the pelvis of the kidney, or you get a shrunken pelvis with an irregular outline (examples of which were shown).

Renal Tumours and Painless Haematuria.

In a certain number of cases where we can detect bleeding coming from one kidney, we are still in doubt as to whether we are dealing with a renal tumour, because we may not be able to feel a very large kidney on that side. In such doubtful cases pyelography is often of great service, as it may show the tumour projecting into the pelvis and altering the shape of the pelvis. Fig. 17 is an example of this. Here a tumour is growing from the lower pole of the kidney and has obliterated all but the upper portion of the renal pelvis.

From Other Abdominal Tumours.

Cases are often brought to me with a diagnosis of renal tumour and very often one is in doubt as to whether one is dealing with a renal tumour or a tumour of the liver, gall bladder, or other abdominal organ. Pyelography soon settles the question. If it shows up a normal kidney the tumour must be something other than a renal tumour.

Renal Pain.

Other cases are sent up to me with a diagnosis of renal pain or renal colic. X-ray examination fails to reveal a stone and the urine is free from pathological elements. In these cases I am accustomed to obtain a pyelo-radiogram. In many cases I can say definitely that the kidney is normal in size and position and cannot be the cause of pain, and such information is of considerable value. In other cases I find some cause for the pain in the kidney, such as a too movable kidney with a kinked ureter.

Stones.

A certain number of stones are of such composition that they fail to show up well on ordinary x-ray examination. In these cases it is sometimes possible to show up a stone by injecting colloidal silver or sodium bromide into the renal pelvis and taking two plates, one at the time, the other five or ten minutes later. Very often one can see the alteration in a calyx or pelvis caused by the stone, and some of the colloidal silver may adhere to the stone and show up in the picture taken five or ten minutes later.

Infections of the Kidney.

In some cases of obstinate chronic pyelitis due to the colon bacillus I find this method of value. In some of these cases the ureter has become narrowed by the disease, in others there is a chronic abscess present in the kidney. If one of

these cases fails to react quickly to renal lavage then I am accustomed to take a pyelo-radiogram to see if I can detect narrowing of the ureter, fibrosis of the renal pelvis, or even an abscess in a portion of the kidney.

Ureterograms.

In most cases it is possible to show up the anatomy of the ureter by this method and exclude phleboliths, glands, etc. In a certain number of cases of uroteric calculus the calculus does not appear on the x-ray plate, especially if the stone is lying in front of bone. A catheter is passed and is found to stop four to six inches up the ureter. A film is then placed beneath the pelvic portion of the ureter, sodium bromide injected, and an x-ray picture taken. This may then show up a stone impacted in the ureter, the ureter dilated below the stone, the catheter running up to the stone, and very often some of the bromide will run past the stone and show up the dilated ureter above the stone and a stricture at the site of the stone. Fig. 18 illustrates this particularly well.

Fig. 19 provides another interesting example. The patient came to me suffering from pyelitis of pregnancy which persisted after the child was born. I catheterized the right ureter and filled it up with colloid silver. It shows very well the dilated condition of the whole ureter. As I have pointed out before,³ the ureter in pregnant women undergoes dilatation due to loss of tone in the muscle of the ureter rather than to pressure of the uterus. This tone returns very slowly after pregnancy. This is the first time I have been able to demonstrate this fact by the ureterogram in the living subject.

Cystograms.

From time to time it is of value to take x-ray pictures of the bladder when filled with opaque solutions. I find that sodium bromide, even in strengths of 10 or 15 per cent., is apt to be very irritating to the bladder and cause great pain, especially if the bladder is inflamed. I therefore prefer to employ 10 per cent. colloid silver. This does not cause any pain in the bladder, and shows up quite well enough for practical purposes. Pictures should be taken in the antero-posterior and also in the lateral positions. The method is useful chiefly for showing up the extent of bladder pouches. One can see the openings of the mouths of the pouches with the cystoscope, but very often one can have no idea as to how large the pouches are until one takes a cystogram (Fig. 20).

Another use for this method is to study the outline of the bladder and prostatic cavity after prostatectomy, and it is also possible to determine by this method whether the ureters are allowing fluid to run from the bladder into the kidney in cases of back pressure. The bladder is filled with colloid silver, and the patient is placed with the head down. In some cases the colloid silver is found to run back from the bladder into one or both kidneys in cases of back pressure, also in some cases of tuberculosis and other infectious of the kidney with dilated ureters.

Finally, Fig. 21 shows a case of recto-vesical fistula in a man following on a fractured pelvis. I was able to cut down, excise the fistula, and cut off the rectum from emptying its contents into the bladder.

Conclusion.

Pyelography has established its position as a valuable method of clinical research in urology. It is indicated particularly in cases of severe abdominal pain of doubtful origin, to determine also the nature of abdominal tumours, and to complete the diagnosis in many cases of haematuria and pyuria.

THE Fifth Congress of French-speaking Paediatricists will be held in Paris on July 10th, under the presidency of Professor Weill of Lyons, when the following subjects will be discussed: (1) The place of pituitary and pineal glands in infantile dystrophy, introduced by Dr. P. Lereboullet. (2) Infantile diabetes mellitus, introduced by Dr. Rohmer of Strasbourg. (3) Congenital scoliosis, introduced by Drs. Mouchet and C. Roederer. (4) The rearing of children outside the family, introduced by Drs. H. Méry and Ribadeau-Dumas. (5) Infantile hygiene in Switzerland from the social standpoint, introduced by Dr. A. D'Espiné and Dr. Reh of Geneva. Further information can be obtained from the general secretary, Dr. Péhu, 24, Place Bellecour, Lyons.

The Milroy Lectures

ON THE

INFLUENCE OF INDUSTRIAL EMPLOYMENT UPON GENERAL HEALTH.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON ON MARCH 9TH, 14TH, AND 16TH, 1922,

BY

MAJOR GREENWOOD,

READER IN MEDICAL STATISTICS IN THE UNIVERSITY OF LONDON; FORMERLY STATISTICIAN TO THE LISTER INSTITUTE.

LECTURE III.

So far we have investigated the hygienic importance of industry by the topographical and historical methods; the result has been to show that some conditions of industrial life are correlated with factors of excessive mortality; we have failed to establish a causal nexus—to pass from correlation to causation. We have now to consider whether other methods of study lead to more precise conclusions. We might, in the first place, retain the topographical method and adopt another unit—for instance, the physique of the inhabitants of different towns. But unfortunately such data as exist are quite inadequate, so I pass to another line of inquiry—namely, occupational comparisons, the unit of comparison being a rate of mortality.

Occupational Mortality in General.

In this region Dr. Farr was, as in so many other regions, the pioneer, and decennial evaluations of occupational mortality in England and Wales go back fifty years; in any compilation of industrial rates of mortality the English statistics are predominant, and they have done duty in arguments and influenced legislation in all parts of the world. It was therefore to be expected that their value would be frequently criticized. The criticisms to which such statistics are exposed fall into two classes: (1) It is doubted whether the rate of mortality shown in a particular occupation does in fact represent the "real" mortality of that occupation; (2) it is doubted whether, even if the former question is answered affirmatively, an excess of mortality in a particular occupation is really cogent evidence that such occupation is unhealthy.

The weaknesses which authorize the criticisms under (1) are: (a) That the basis of classification has not only been changed from census to census, but is still (I am speaking of the census of 1911) "only truly occupational in parts, being as regards manufacture for the most part frankly industrial. Thus the driver of a motor car is classified as a chauffeur—his occupation; but the workman engaged upon its manufacture is classed either as a motor-car chassis maker or as a motor-car body maker—headings which indicate merely the industry in connexion with which he plies his trade, whether it be that of tinsmith, moulder, fitter, sandblast-man, painter, or what not" (General Report of Census of England and Wales, 1911, Cmd. 8491 of 1917, p. 12). (b) That there is no guarantee that the occupational description in virtue of which an individual contributes to the total years of life lived, to the denominator of the fraction measuring the rate of mortality, will be the same as that upon the death certificate which admits him to the numerator.

The occupational complexity of our own profession is not greater than that of most industries, but it sufficiently illustrates the point. The industrial description of all persons admitted to the Medical Register since 1886 would be, I suppose, physician, or surgeon, or accoucheur, any one of the terms implying both the others. Consider the troubles that would await a statistician who wished to determine whether the rate of mortality of physicians in the occupational sense differed from that of physicians in the industrial sense. It is quite as much for these reasons as for the desire to base rates upon large numbers that the statistical grouping of occupations is a coarse one.

There is a further point: although the method of inquiry which we are discussing formally renounces geographical or topographical differences, for some of the largest industries of the country the renunciation is purely formal. In 1911 83.2 per cent. of the total number of persons engaged in cotton manufacture were enumerated in Lancashire and nearly all the remainder in the adjoining counties of the West Riding of Yorkshire and Cheshire; 88.7 per cent. of those engaged in wool and worsted manufacture were enumerated in the West Riding of Yorkshire. When we compare the rates of mortality of cotton manufacturers with those of, say, printers,

we are comparing the conditions of persons concentrated in one part of the country with those of workers distributed all over it.

One sees, then, that the returns must be used with great care, even when we wish to answer the simple question whether such or such an occupation experiences a high rate of mortality. When we go on to ask the further question, Is the occupation itself responsible for that high rate of mortality? the difficulties are very much greater, because of occupational selection and the movement from one occupation to another, which may be due to a deterioration in health.

To seek fine shades of meaning in the statistics of the many scheduled occupations, to subject them to the meticulous analysis which modern statistical artists have devised, is often to waste time. But there is something of value in the data, and even the severest critics have not spared themselves in the search for gold amongst large quantities of quartz. I shall restrict myself to a very few broad comparisons.

Special Occupations.

I shall speak of twelve industrial groups, including the clergy, commercial clerks, agricultural labourers, printers, cotton manufacturers, wool and worsted manufacturers, tailors, and shoemakers. The selection has not been made at random. In the first place the numbers of lives exposed to risk—that is, thrice the enumerated census populations—are large, more than 100,000 in each instance. In the second place the groups illustrate different phases of industrial life. The clergy, whose mortality I take as a standard, typify a sober, clean-living, educated, but not wealthy, group under highly diversified environmental conditions. Commercial clerks typify the less successful lower-middle-class population of cities; agricultural labourers are, in the main, very poor persons living in the country, whose sons and brothers swell the ranks of the industrial townsmen; cotton and woollen manufacturers are examples of skilled workers localized in a particular area; printers are skilled artisans not concentrated in any one part of the country; tailors are heterogeneous;

Cotton manufacturers ...	169	416	250	503

while shoemakers can be divided, very roughly, by a geographical test into factory and non-factory operatives. In the tables are shown the rates of mortality in four decennial age groups from all causes, from phthisis, from pneumonia, and from bronchitis—all expressed as percentages of the rates upon clergymen. I have also inserted in these tables the combined results for the textile industries, for textile dyers and bleachers, also the rates peculiar to one class of printers, hand compositors, and those appertaining to boot and shoe or slipper makers enumerated in the counties of Northants and Leicester, the most important concentration of factory boot manufacture in England and Wales.

Let us begin with a general survey of mortality in age groups. At 25 to 35 agricultural labourers experience a mortality of some 50 per cent. excess over clergy; the skilled industrials of the north-west show a greater excess, but shoemakers—whether the factory operatives of the Midlands or shoemakers as a whole—are the worst off, having two and a half times the death rate of the clergy. The principal assigned cause is phthisis, which amongst the operatives of Northampton and Leicestershire is five times as fatal as amongst clergy and twice as fatal as amongst textile workers. Is this attributable to (a) climatological differences, (b) differences of recruitment, or (c) differences of factory environment? Answers to these questions cannot be much better than guesses. But if—and the speculation is plausible—the nearest area of recruitment is that most usually drawn upon to feed an industrial centre, one might suppose that the supply of unsalted youth, of genuine rustics, to be found within fifty miles of the great Midland boot factories is very much greater than that available for the cotton mills; but, as said before, this is only a speculation. Such little direct evidence as we have respecting immigration into the boot-manufacturing centres does not suggest any large inward movement.

In the decennium 1881-90, indeed, Northampton gained considerably by migration (854 males and 1,030 females in the age group 15 to 35, but in the following decennium both age groups show a small outward balance (Welton, 357). In a paper contributed to

the *Journal of the Royal Statistical Society* in 1912 Mr. Welton summarized the changes (all ages) shown by the census of 1911 both in Leicester and Northampton. Each showed an *outrand* balance—Leicester of 7,103 males and 3,680 females, Northampton of 2,476 males and 2,040 females. These results do not of course prove that there has not been a considerable inward movement from the country compensated for by emigration of the town born, but clearly they are not evidence in favour of the hypothesis suggested, and must therefore be specially emphasized.

Another way of testing the hypothesis is to examine whether the ratio of mortality rates, using the clergy as a standard, has increased over the last sixty years, since the transformation of the shoe manufacture from a home to a factory industry has been largely effected in that period, especially during the last twenty years. As a matter of fact, the relative mortality at the earlier ages has increased.

Thus, combining Dr. Farr's 1860 and 1870 enumerations, one has for the age group 25 to 35 per mille rates of mortality of 4.7 (clergy) and 9.52 (shoemakers), giving a percentage ratio of 203 for the shoemakers; in the enumeration of 1890-92 the rates are 4.2 and 7.66—ratio 182; in 1900-2, 2.7 and 6.33—ratio 234; while, as we have seen, for 1910-12 the ratio is 249 for the Leicester and Northants shoemakers and 247 for all shoemakers. The ratios in the next age group are 180, 218, 240, and 250; at 45 to 55, 126, 189, 179, 163; at 55 to 65, 135, 139, 128, 120. These figures are consistent with the view that the change from home to factory industry—despite the notorious objections to the former—has not been *relatively* favourable at earlier ages, and are therefore consistent with the hypothesis. But they do not constitute a strong argument.

The rate of mortality of commercial clerks should be a source of painful reflection; in this age group it is exceeded by shoemakers alone; at 35 to 45 it is the highest of any in our table, and holds the same place in the decennium 45 to 55. No doubt this group bears much the same relation to middle-class industries as the group general labourer does to the hand-working classes—it includes, that is to say, a sensible proportion of weaklings in the lower and of failures in the later age groups. But if we admit any other factors of mortality than those assignable to selection we shall not doubt that the hygiene of what used to be called the black-coated labourer needs as much attention as that of the industrial worker. Next to clerks come printers, whose mortality from phthisis is far beyond that of any group save the shoemakers; their mortality from bronchitis and pneumonia is above the average, but less than that of the textile workers, who experienced a much smaller mortality from phthisis. The two great textile groups show some difference one from another: the cotton manufacturers have the lower general mortality, and the lower mortality from each special cause named.

In the age of industrial maturity, 35 to 45, the position relatively and absolutely has changed; all our employed groups except agricultural labourers and the Midland bootmakers stand worse in terms of the mortality of the clergy than they did. The shoemakers still have the highest mortality from phthisis, but their relative mortality is no worse than before; both the textile groups have deteriorated, and the tailors have deteriorated a great deal. If the bad showing of the Midland shoemakers in the earlier ages as compared with the cotton and woollen operatives was due to the larger proportion of unsalted rustics, then a selective mortality has just enabled them to keep station while the textile workers are beginning to falter. Agricultural labourers, despite the winnowing out of the ambitious fit who have passed into the towns, show no appreciable deterioration.

In the next age group all our industrials have improved relatively to the standard, but this fact must not be made the subject of too comfortable reflections. There are weaknesses in every method of statistical comparison, and the weakness of the particular one here used is that arithmetical necessity imposes upon the percentage ratios some degree of convergence.

It were too ambitious to speak of a "law" of mortality as a function of age, but if we suppose that the force of mortality is compounded of an element independent of age and an element increasing in geometrical proportion with age—the hypothesis of Gompertz, or, as it is usually termed, the Makeham-Gompertz hypothesis—it is plain that with advancing age two formulae of mortality having different constants will converge nearer and nearer one to the other. So that if we find the ratios in my tables growing larger we may certainly infer a deterioration, but if they grow smaller we cannot infer an improvement without special examination (which the data do not justify).

The order of the groups is now quite different: the Midland bootmakers, although still afflicted with a high rate of phthisis, have the next lowest mortality from all causes to the agricultural labourers; tailors are almost as bad as

commercial clerks, but very little worse than cotton manufacturers, who stand higher than printers and appreciably higher than woollen goods makers. In this age group the cotton workers begin to be seriously troubled by pneumonia and bronchitis, responsible for 8.7 and 5.8 per cent respectively of all deaths, and at rates 77 and 60 per cent, in excess of those upon woollen and worsted workers. You will remember that the mortality from these respiratory diseases is above the average both in Westmorland and Cumberland, so that part of this excess may be climatological, not industrial.

In the age period 55 to 65, the textile workers have reached the worst place, while the Midland bootmakers stand best amongst the industrially employed; bronchitis, responsible for 10.7 per cent of all deaths in the industry, is much more than twice as fatal to the cotton makers as to the shoemakers, and more fatal—in the proportion of 8 to 5—than to woollen and worsted makers. Printers, although still liable to an excessive mortality from phthisis, stand better than the textile operatives.

Let us concentrate our attention still more closely upon these particular groups of contrasting workers—the cotton manufacturers of Lancashire, the woollen workers of the West Riding, the shoemakers of Northants and Leicester, and the printers of all England. In which of these groups of skilled artisans is the largest number of maximally productive years available? Using the life table method, we find that the average number of years lived from 25 to 55 is 27.58 for cotton manufacturers; 27.39 for woollen manufacturers; 27.23 for printers; 27.17 for the boot and shoe makers in Leicestershire and Northamptonshire. No practical importance attaches to the small differences between these figures; we may take it that in each occupation some 91 per cent of the theoretically possible term of years is enjoyed. It is, however, instructive to see how quite different courses of mortality have led over this period to substantially the same final result. The textile workers with their low adolescent mortality counterbalance, in this comparison, the increasingly unfavourable effects of later adult mortality. Had we carried the calculation over another decade we should have found an advantage amongst the shoemakers, who were left at 55 with substantially the same number of survivors of entrants at 25 as the cotton manufacturers—namely, 7,719 cotton makers and 7,716 bootmakers out of an initial 10,000 in each case.

These results admit of certain deductions and prompt certain speculations. The deductions are these. Although phthisis is by far the most deadly of the causes of mortality in early adult life, it does not follow that an industry of which phthisis takes a heavy toll is an unhealthy industry, if we use as our measure of healthiness the proportion of years lived in maturity. We can hardly even suppose that these are pathologically weighted years, that for instance the 27 odd years lived by printers between 25 and 55 are more smitten by ill health than those of the cotton makers; because after 55 the mortality rates of printers are not worse than, but better than, those of cotton manufacturers. Dr. Tebb and I reached the same conclusion by another path. We found that if a very much larger number of occupational groups were treated by the method of correlation deaths from phthisis as the dependent and deaths from all other causes as the independent variable, both printers and shoemakers (tailors, bookbinders, hosiery makers, and cabinet makers were in the same case) experienced a mortality from phthisis out of proportion to their mortality from other causes. Miss C. M. Thompson (see Greenwood, (1), 336) also found that in the London boroughs there was little correlation between the death rate from tuberculosis and from other diseases independent of that between tuberculosis, overcrowding, and industrial employment. Accordingly we may, I think, conclude that the problem of phthisis-ridden industries is not exclusively a problem of the recruitment of weaklings. Of course this would be a mere truism if my survey included any of the occupations dealt with by Professor Collis in his Milroy lectures, subject to a specific risk, such as that of the Sheffield grinders, but I have entirely excluded these from my consideration. It further appears that the special liability of workers in these occupations is not inherent in the art itself. Thus the whole group of shoemakers, which must include a very large number of non-factory shoemakers, does not at ages under 45 experience so heavy a mortality from phthisis as the Northampton and Leicester group, nor did Dr. Tebb and I find the same excessive mortality from phthisis amongst Dutch shoemakers. Again, the English

cotton manufacturers have relatively little phthisis, but the same class of operatives in Massachusetts (Perry) suffer greatly from the disease.

The Validity of the Statistical Method.

A point has now been reached in our journey at which we may pause and ask ourselves whether any further progress be possible without the aid of other implements than those we have so far employed—namely, general epidemiological and elementary statistical methods. Within the last few months two eminent members of our profession have rated the statistical method low. In a new edition of his *Technique of the Test and Capillary Glass Tube* Sir Almroth Wright expresses his conviction that in therapeutic research clinical experience "unaided by apparatus and technique" is "of infinitely little account," and statistical evaluation (except for propagandist purposes) but "old abasing God's patience."

The name of Sydenham warns us that either "research" or "apparatus and technique" must be understood in what theologians called a non-natural sense before we can accept Sir Almroth's condemnation of clinical experience as an instrument of therapeutic advance. By some such casuistry we might hope to bring the Heberdens, the Jenners, and the Murchisons from under the edge of Sir Almroth's sword. But our charity ought not to reach the "statistical evaluators," since, I gather, their "accepted statistical doctrine teaches that all false judgements are quashed when we collect enough cases." These persons, it seems, have but a single method of procedure—namely, "arbitrarily selecting one particular criterion and counting the exact proportion of cases in each group which satisfy and fail to satisfy it." The doctrine is justly stigmatized by Sir Almroth as false, and the method argues a strange limitation of outlook. Were Sir Almroth able to cite any instance of a statistician who accepted this heretical doctrine and exemplified this erroneous practice, the conclusion he invites his readers to draw would attain the quite respectable rank of a fallacy *a dicto secundum quid ad dictum simpliciter*. No such instance being afforded, Sir Almroth merely prompts a reference to Joh xxviii, 2, and provides one more case of the darkening of counsel.

Sir Arthur Newsholme, who, having a wider experience of statistical methods than Sir Almroth Wright, has no doubt a higher opinion of their value as instruments of research, still seems in agreement with Sir Almroth to the extent of assigning to the statistician a place in the propagandist rather than in the research department of the public health service.

If I have correctly followed Sir Arthur's argument developed in his address to the American Statistical Association, he would assent to the following propositions: If in a particular city, or group of cities, the rate of infant mortality began to decline after the establishment of infant welfare centres, and continued to decline *pari passu* with the extension and development of such centres, it would be proper to use the statistics as evidence that the establishment of the centres had a causal relation to the decline of infant mortality. If it were also found that in some other group of cities where no such centres had been established the rate of infant mortality declined synchronously with that of the former cities and to the same extent, this second group of statistical facts should in no way modify the conclusion attempted to be drawn, and impressed upon the general public by statistical charts, in the former case. Sir Arthur Newsholme is anxious to repudiate an intellectual heresy which popular wisdom has

we say, infant mortality declines
immities, it does not follow that

welfare centres and care committees are useless. But it does follow that infant salvation may be attained in more ways than one, and we may fairly ask whether the appraisalment of these various other causes is not a proper object of scientific research, to attain which the statistical method is a valuable instrument. I believe that Sir Arthur, in his zeal for the repudiation of Sabellins, has not sufficiently guarded himself against the wiles of Arius. It is, no doubt, very wrong of non-medical statisticians to confound the persons of the etiological Trinity; but it is quite easy for the administrator whose zeal for laboratory results may not always be tempered by expert knowledge to divide the substance. "Il existe," said a great physiologist, "toute une école médicale dont les sectateurs n'ont, bien entendu, jamais hanté les laboratoires, mais pour qui le mot 'expérience' tient lieu de tout, comme le 'tarte à la crème' de la comédie" (Bert, *Pression barométrique*, p. 516). This sarcasm is not entirely unmerited by some who assure us that the rôle of the publicity agent of the experimental patho-

philosophy of the administrator is not temporary in the bacteriological department. I suppose many medical officers of health believe that the reduction of sources of direct infection *in vitro* is the most important means of combating the spread of fatal tuberculosis. The segregation of "open" cases of phthisis has been eagerly recommended, statistics correlating such measures with the declining death rate have been widely circulated, and it has been asserted that such measures are the administrative expression of experimental truths.

But the experimental pathologists of our time are not unanimous. Professor Calmette, indeed, seems to regard exposure to an infection held within not very clearly defined bounds to be a blessing in disguise. He dissents from much which was recently orthodox in respect of paths of infection, reducing the importance of milk contamination to a very modest place, although he is quite willing to "considérer comme dangereuse, surtout pour les jeunes enfants, l'ingestion répétée des huîtres crues riches en bacilles" (313). Upon the basis of experimental and observational studies of the last twenty years the etiological problem of tuberculosis has been formulated by men who are certainly not "armchair statisticians" in terms very different from those which inspired the faith of our sanitarians even ten years ago. Colonel George Bushnell of the United States Army Medical Service has recently published a summary of this evidence. Having epitomized the now substantial literature testifying to the havoc wrought by tuberculosis upon a native race exposed to the influences of civilization suddenly, having made it appear that these ravages are largely independent of the goodness or badness of the conditions of life, and having contrasted the extent and clinical evolution of the tuberculosis of the civilized races with that of the savages, Colonel Bushnell writes:

"Civilized man can never escape the dangers of infection with the tubercle bacillus. But if we did escape the danger of infection, we should also lose the benefits of tubercularization. At the time when control of expectoration first bulked so largely in the eyes of the sanitarian the community was divided in his thought into two classes as respects tuberculosis, the tuberculous and the healthy. Very slowly and reluctantly since that time the knowledge of the true facts has been acquired, and still more slowly and reluctantly has it been disseminated—in fact, it still seems incredible to many that tubercularization should be so wellnigh universal as it undoubtedly is. If it seems likewise a terrible fact that conclusion is erroneous. The error lies in the assumption that tuberculosis is necessarily an evil. We fix our eyes upon the advanced case of tuberculous disease, a pitiable sight indeed, and that for us spells tuberculosis, but we forget that such a case is the comparative exception, the illustration of a failure in immunization; we forget that the majority of the population never know that they are tubercularized!" (182). Dr. K. F. Andvord of Christiania, in a very suggestive paper issued a few months ago, has reached conclusions which differ from those epitomized by Colonel Bushnell in one respect, but in others are similar to his. Dr. Andvord holds that in a tubercularized community the source of nearly all fatal tuberculosis of adult life is infection during the first year, the fatal issue being a consequence of auto-reinfection. To support this thesis he relies upon two lines of argument. In the first place, the direct evidence of Bergman of Upsala, who has investigated the after-history of 1,604 children of tuberculous families. Bergman found (I am epitomizing at secondhand—the original is not accessible to me) that all the persons in his sample who died of tuberculosis in childhood or adult life and 90 per cent. of those still alive but suffering from clinically demonstrable tuberculosis had been exposed to infection within the first years of life, but that not a single death from tuberculosis could be found amongst those whose exposure had been deferred until after the fourth year. In the second place, Andvord shows that the age incidence of fatal tuberculosis, and the statistical observations of Dreijer, Bang, Harbitz, and others on the frequency of a tuberculous or "pre-tuberculous" condition, may be reconciled on his hypothesis. Hence he thinks "the most effective prophylaxis would be the protection, by every possible means, of children, notably those in the first three or four years of life, from the more severe infections, either by removing the source of infection from the children's neighbourhood, or, if possible, by the isolation of the children" (115). He also thinks it necessary to obtain more accurate knowledge of the stages which precede pulmonary tuberculosis, particularly in late childhood and adolescence, and "at least as important to attempt to minimize or remove predisposing causes, and thus possibly to prevent re-auto-infection as to protect the individual from the danger of infection by his surroundings" (116). A practical conclusion in harmony with that of my distinguished predecessor in this lecturship, the late Dr. Bulstrode.

I have not cited these results because I hold them to be ascertained truths (the reasoning seems to me loose, and the total neglect of selection strange), still less for the purpose of twitting those who have rebuked the medical shortcomings of the lay biometricians with being themselves somewhat in the rear of the pathological march of mind. But I may fairly claim them as justifications of the standpoints of Professor Karl Pearson, Dr. John Brownlee, Professor Raymond Pearl, and, if I may venture to add my name to this distinguished company, myself. Whether it be true in the more general sense of Colonel Bushnell's argument that the fatal evolution of tuberculosis in members of a tubercularized community is a function of environment in its most general expression; or whether, as Dr. Andvord believes, this pathological accident can only occur to those infected early in life; or, again, whether a change of survival values be not the really significant thing: to discover the intrinsic or extrinsic factors over and above the bacillary infection is an object of the greatest importance. We cannot afford to neglect the intrinsic predisposing factors to which Professor Pearson has devoted attention, the contrasting epidemiological types which Dr. Brownlee has displayed, or the general physiological

ANEURYSMS OF THE THORACIC AORTA INVOLVING THE LUNG.

BY

JAMES FANNING, M.B., B.S. LOND.,

HOUSE-PHYSICIAN, HAMPTSEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.

THE two cases of aneurysm of the thoracic aorta described below present several features of considerable clinical and pathological interest. Both aneurysms ruptured within a fortnight of each other while under observation in hospital, and in each case the aneurysmal sac produced extensive changes in the lung. The second case was particularly interesting in its close simulation of chronic pulmonary tuberculosis.

CASE I.

W. H., widower, aged 53, a commercial traveller, was admitted to Hampstead General Hospital on January 31st, 1922, with a history of four years' gradually increasing dyspnoea on exertion. There were also attacks of more or less severe pain chiefly at night, and lasting from half an hour to one hour. Pain was felt at the back of the shoulders and down the right arm, with a general feeling of tightness in the chest. This was also worse after exertion. He had a chronic slight cough, and at times suffered from palpitation. There had been no dysphagia, no oedema, and no haemoptysis. He did not think he had been losing weight.

Two days before admission he suddenly collapsed after getting up in the morning, and lost consciousness for three-quarters of an hour. On recovering he felt very weak, and complained of pain all over the chest; later he developed a troublesome cough with haemoptysis. He had always been healthy previously.

Condition on Admission.—The patient was a rather thin and anaemic man in a very weak condition. There was very little dyspnoea while at rest. There was a pulsating swelling immediately to the right of the sternum, having an area of about 2½ square inches, and considerable diminution of movement of the right chest. The percussion note was dull all over, back and front, while the breath sounds were very weak and bronchial. Vocal fremitus and resonance were increased. There were no adventitious sounds. The pulse rate was 70, and the rhythm equal and regular. The volume was moderate and tension poorly sustained. There was no inequality of the radial pulses. The cardiac apex was in the fifth space, 1 inch outside the nipple line, and was heaving in character. The heart sounds were normal, and were heard clearly over the swelling. The systolic pressure was 145 mm. and the diastolic 110. The left pupil was slightly larger than the right.

Progress.—The patient remained fairly comfortable in bed for over a month. The cough and haemoptysis continued. There were occasional slight attacks of dyspnoea. The only fresh sign that developed was a slight oedema of both forearms. The temperature varied from 98° to 101° F. On March 7th, at 5 a.m., free haemorrhage took place suddenly from the mouth, and the patient died in five minutes.

Post-mortem Examination.—A small mass of blood clot about the size of a large walnut was found immediately beneath the chest

wall in the region of the swelling noted before death. The left lung was large and emphysematous, and covered the left border of the heart and pericardium. About 12 oz. of dark yellow fluid were present in the right pleural cavity. The right lung appeared shrunken, was dark in colour, and felt solid. It was not possible to distinguish the lobes. The heart was small and appeared normal. The aorta about one and a half inches above its origin opened into an aneurysm about the size of a foetal head. It occupied what appeared to be the right lung, the remnant of which was stretched over the sac as a thin shell. The cavity of the aneurysm was full of laminated clot, which dropped out through the anterior wall of the sac, and was directly continuous with the walnut-like mass above mentioned. The aorta was atheromatous, and showed marked syphilitic arteritis.

CASE II.

Mrs. E. S., a widow, aged 50, employed as a cook, was admitted to hospital on March 12th, 1922, with a history of six months' illness of gradual onset. Her chief complaint was pain round the lower part of the chest, "crushing" in character, coming on directly after food. There was no vomiting, but considerable flatulence. The appetite was poor, and she did not sleep well. She had been getting much thinner recently. There had been no night sweats. There was slight dyspnoea on exertion. For the past month she had been bringing up blood by the mouth; she said she coughed up a little every day mixed with frothy sputum, the blood being sometimes bright in colour and sometimes dark, while at intervals of about a week she brought up larger quantities (about half a pint) in clots. These large quantities she thought she vomited, although solid food was never noted in the vomit.

Condition on Admission.—The patient was a wasted, anaemic woman. There was moderate enlargement of the terminal phalanges of the fingers. The temperature was 100° F., pulse rate 100, and respirations 24. On inspection of the chest there was definite flattening at the left apex with diminished expansion. On palpation there was slight pulsation below the left clavicle. The percussion note over the left apex and subclavicular region in front and over the left apex behind was dull. Towards the outer part of the dull area the breath sounds were diminished, and vocal fremitus and vocal resonance were less than normal, but internal to this loud cavernous breathing was heard. A few fine crepitations were present. The pulse was equal and regular, of small volume and moderate tension. The apex beat was in the fifth space within the nipple line, and there was no enlargement or displacement of the heart. The sounds were normal.

Progress.—For the first two days after admission the patient was continually bringing up clotted blood in small quantities. The blood appeared in the pharynx without effort, and was mixed with sputum or food. There was a slight cough, but the blood did not seem to appear with the cough. No sputum was obtained. On the second day after admission she had a sudden and severe haemorrhage; she became blanched and almost pulseless at the wrist. However, she made a fair recovery from this attack, but the bleeding continued; and at times the blood was undoubtedly mixed with fluid stomach contents. Melæna was a marked feature in the case during this time. Pain in the upper left chest was also complained of. The temperature varied from 99° to 100° F. The patient gradually became weaker and more anaemic, and died quite suddenly, but without external haemorrhage, on March 19th, seven days after admission.

Post-mortem Examination.—An ulcer about 1½ inches by 1 inch in diameter was found in the oesophagus at the level of the bifurcation of the trachea. Through the base of this ulcer a mass of blood clot presented. The trachea was normal. The upper half of the upper lobe of the left lung was heavy, deep red in colour, felt solid, and was adherent to the thoracic wall. An incision showed a mass of dense laminated blood clot of a pale buff colour, around the periphery of which was stretched a thin layer of lung tissue. The mass was about the size of a large orange, and contained a cavity no larger than a walnut, which communicated with the arch of the aorta. The lumen of the aorta itself was scarcely altered. There was slight atheroma and syphilitic arteritis. The heart was small, and the valves were normal. The right lung was quite healthy. The intestines contained a considerable quantity of altered blood.

The way in which, in the first instance, a whole lung, and in the second instance a localized part of the lung, were converted into aneurysmal sacs is one of the most interesting features of these cases. The strength of the sac in each instance seemed to be in its dense lining of laminated clot. As regards the origin of the bleeding, in the first case it probably came from the remains of the bronchioles in communication with the sac, while in the second case it is possible that there was a double source of haemorrhage—from the lung and from the oesophagus. Another observation which is well exemplified is the remarkable pathological changes that can take place in the thoracic aorta without producing any change in the cardiac musculature. In the first case the heart was certainly displaced, and, clinically, appeared to be hypertrophied; but the post-mortem examination showed that in neither case was there any hypertrophy or dilatation.

Clinically, Case II presented an interesting problem in diagnosis. The history of progressive wasting, cough, and haemoptysis, together with the localization of the physical signs to the left apex, pointed to an apparently advanced case of chronic pulmonary tuberculosis with cavitation. The

slight pulsation present suggested the possibility of aneurysm, but this diagnosis appeared so unlikely that it was dismissed; it was supposed that the pulsation was conducted from the base of the heart uncovered by retracted lung. There was also some difficulty in determining the source of the haemorrhage, but this seemed explicable by ascribing the haematemesis and melæna to blood swallowed from the lung. Indeed, the symptoms of pain after food and haematemesis had resulted in the case being sent in as carcinoma of the stomach.

I am indebted to Dr. G. A. Sutherland, under whose care both these cases were, for permission to publish these notes.

THE RADICAL CURE OF HAEMORRHOIDS: MODIFIED WHITEHEAD OPERATION.

BY

SIR JOHN O'CONOR, K.B.E., M.A., M.D.,

SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AIRES.

I wish to invite again¹ the attention of surgeons to a very simple method of performing the only operation for the cure of haemorrhoids which, in my opinion, is worthy of the term "radical." And it affords me intense gratification to be able to state that in 1904 the distinguished originator of the procedure honoured me with his approval of my humble modification²—namely, that primary dilatation of the external sphincter entailed an unnecessary magnification of perspective which might readily induce anatomical obfuscation with disastrous operative results.

Method.

1. Limit primary dilatation to the insertion of the right index finger in quest of concomitant polyp, ulcer, stricture, etc.
 2. Apply a pressure forceps at junction of skin and mucous membrane to each of the four cardinal points of the anal circle.
 3. With adjoining pairs of forceps held in opposing traction make a rapid dissection with a large straight blunt-pointed scissors from "point" to "point" until the skin is completely detached from mucous layer.
 4. Apply another pressure forceps to the cut edge of the latter between each of the four forceps originally placed. This makes the operator master of the situation.
 5. Grasp the eight forceps in the palm of the left hand, insert the left index finger into the rectum, and then cut lightly all around with scissors until the external sphincter appears well in view.
- It is absolutely essential at this juncture to define this muscle and keep it constantly in sight and pushed upwards, always remembering that all cutting must be done below and external to it.
6. Continue snipping round with scissors until the "White-head adit"³ (submucosa) is exposed; then bear Cunningham's *Anatomy* in mind: "The submucous coat is composed of loose areolar tissue, which allows of free movement of the mucous layer on the muscular coat, and which also admits, under certain abnormal conditions, of a prolapse of the mucous membrane through the anal orifice. . . . The haemorrhoidal plexus of veins is contained in this layer."
 7. With the left index finger still retained in the rectum as guide, and the eight forceps in the left palm making traction, continue severance of the attachments to the muscular coat until the haemorrhoidal cylinder can be peeled out of its bed by a few strokes of the back of scissors or other blunt dissector.

8. Then make a vertical slit in the protruded cuff up to the level of the "supra-Morgagnian"⁴ circle; commence a continuous Triollot catgut suture at the apex of the slit, drawing the "red" mucous membrane into accurate apposition with the skin; then proceed, cutting transversely, half-inch by half-inch, at the level just mentioned; carry on, *pari passu*, the continuous suture; stop and forceps every spurting vessel and ligate same at once, so that at the last snip of the scissors nothing remains to be done except to complete the few final loops of the suture.

Abjure the employment of what is fatuously styled by clammers "a continuous haemostatic suture,"⁵ and of what is called by tinkers a soldering iron, in any part of the intestinal tract.

9. Having introduced a morphine suppository and a slender roll of dry gauze into the rectum, apply a dry gauze dressing and change same daily.

10. On the fifth morning give the patient one ounce of castor oil, sponge the part after each evacuation with warm permanganate lotion, add a warm permanganate sitz bath daily, and reapply a dry dressing.

11. On the seventh morning instruct the nurse to insert the right index finger (anointed) into the canal, and to educate the patient to do the same daily for two months. Do not forget, before he departs, to prescribe a pot of zinc and boracic ointment for this purpose. If any tags are in evidence on the ninth day apply a little eucaine and snip them off with scissors.

I have nothing further to state beyond the fact that not once in every fifty operations do I hear of any contraction or any other complication following this method. All the patients are discharged cured by the fourteenth day, and the time⁶ occupied in the actual operation varies from five to ten minutes.⁷

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

AN AORTIC MURMUR.

As early as 1910 I noticed an aortic systolic murmur in apparently healthy persons. I observed it first in my own case, and after that in many infirmity patients, and later in many recruits and serving soldiers.

I was encouraged by Dr. James of Edinburgh to investigate the murmur, and, as mentioned by me in a letter to the *JOURNAL* recently, I had satisfied myself as to its cause and written an account of it before the war. It is heard over the aortic area, is systolic, and has generally the characteristics of an aortic stenotic bruit. The probable explanation was arrived at by a study of the flow of water in a rubber tube with a Higginson's syringe for the propelling force. If the tube be auscultated, the flow of water being kept up by the pressure of the foot on the ball of the syringe, a bruit can be produced by applying pressure to the tube. It is produced either by proximal or distal pressure, but is more audible in the former—that is to say, the sound is propagated against as well as with the flow of the water.

From this experiment I conclude that pressure on an artery such as the carotid produces a bruit which will be propagated both with and against the blood flow.

If the aortic area be auscultated and pressure be made with the finger so as partially to occlude the subclavian artery above the clavicle, a distinct systolic bruit is heard. In the actual patients it was sometimes present and at other times absent. It was found that the drawing aside by the patient of his clothing to permit of auscultation brought the sound into existence, and that with the arms by the side it could not be heard.

The subclavian artery passes over the first rib and under the clavicle, but is separated from the latter by the subclavian muscle, the action of which is to approximate the rib to the clavicle. Other muscles perform the same action—namely, the scalenus anticus, the deltoid, the pectoralis major, and also the pectoralis minor.

It would therefore appear that the artery can be, and is, very easily compressed by muscular action, and that when so compressed a bruit can be heard. Many persons by contracting their muscles can obliterate the radial pulse. The bruit can be obtained in almost any person. I have heard it in children, young adults, and elderly persons, and think it would be obtained in anyone provided the artery wall was compressible and the compressing machine in working order. The bruit would not be heard in a patient who was stripped to the waist and had his arms by his side.

While I do not think the bruit is of clinical importance, as it often occurs in medical examination for life assurance, I think it warrants an explanation.

My conclusions are: (1) That an aortic systolic bruit is very frequently heard over the aortic cartilage in the absence of any diseased condition. (2) That a large proportion of such bruits are due to the position of the arms at the time of examination, or rather the state of contraction of the muscles

760 MAY 13, 1922]

HOSPITALS OF THE FUTURE.

of the shoulder girdle. (3) That such bruises will mostly disappear if the patient is stripped to the waist and has his arms hanging loosely by his sides.

THOMAS LINDSAY.

STREPTOCOCCAL SORE THROAT.

THJÖTTA has reported an epidemic of angina faucium in a Norwegian military camp last July. During the past three months I have had seven cases of what I termed septic sore throats very similar to those described by Thjötta—three in one household and two in two other families. The symptoms were almost identical in all the cases—namely, high fever, general pains, and marked dysphagia; in all the fauces were highly congested; in four the tonsils showed discrete collections of debris which spread and coalesced, covering the entire tonsil but not spreading beyond. In the remaining three cases punctate collections of membrane appeared, and within a few hours covered the surface of the tonsil with a whitish, easily detached membrane. These three cases clinically appeared so much like diphtheria, that in two of them antitoxin was given as a precautionary measure. In five of the cases bacteriological examination during and after the attack gave a pure streptococcal infection. In two there was a diphtheroid bacillus as well.

In the first household the first and second cases each developed quinsy after a week. The third case clinically was so much like true diphtheria that it was kept under observation for three weeks; antitoxin was given as a precautionary measure, although the swabs only showed streptococcal infection. All the cases recovered.

A. MACFETH ELLIOT, M.D.

London, S.W.

Reports of Societies.

HOSPITALS OF THE FUTURE.

The annual oration of the Medical Society of London was delivered on May 8th by Mr. H. J. WARRING, C.B.E., F.R.C.S., who put forward some suggestions with regard to the future of hospitals, public and private. The President, Mr. JAMES FERRY, occupied the chair.

Hospital Provision for the Non-Necessitous.
Mr. WARRING said that during recent months there had been a good deal of discussion concerning the position of medical men in hospitals, mainly with regard to the allocation of money paid as contributions towards maintenance either by the patients themselves or by some public or other body on their behalf. All this discussion appeared to have centred round the rights of the medical staff, while the rights of patients and of the hospitals themselves had been less debated. He proposed to discuss the hospital question on a broader basis. The so-called voluntary system was well established and would continue to have centred round hospitals, to which at all times the necessitous poor would continue to provide funds for the maintenance of the hospitals; and the medical profession also would continue to act as a profession, and would not become a trade, with a trade union to dominate its policy and retard its progress.

Since the establishment of our voluntary hospitals the benefits of those institutions in the investigation of disease and its treatment had been very much better provided with the result that the poor had been very much better provided for than the upper and middle classes. The general public had now realized this fact, and within the last decade there had been an increasing demand on the part of the non-necessitous for entrance as in-patients into voluntary hospitals. These people had come to recognize that the diagnosis and treatment of disease with expedition and success could be carried out better in a large and properly equipped public institution than in a nursing home, which was very often an ill-adapted, second-class, mediocre private residence.

The population from the hospital point of view might be grouped into five classes: (1) The necessitous poor who could make no contribution; (2) The necessitous poor who could make a small contribution towards maintenance, but nothing towards medical treatment; (3) The necessitous, but always poor, who could afford the cost of their hospital accommodation and maintenance, but could not pay for medical treatment; (4) The middle classes, who could pay for ordinary hospital accommodation and maintenance, but could not pay for treatment; and (5) the opulent. The first three of these classes were already provided for, but there was no accommodation in the general hospitals for the other two.

Annexes for Paying Patients.
The solution of the difficulty with regard to the middle classes and the better-to-do, who had hitherto not been able to obtain the standard of institutional attention and treatment open to the necessitous, was to build a separate block distinct from but affiliated with the public hospital. Most hospitals were not built in such a way as to allow of the necessary reconstruction to admit these classes of patients; moreover, in most instances the funds utilized for the building of those hospitals had been given or bequeathed for charitable purposes. On the other hand the special departments, such as the pathological laboratories, the x-ray rooms, and so forth, were sufficiently equipped to serve not only for all the charitable purposes, but for paying patients as well. Mr. WARRING showed plans which he had prepared for a private block adjacent to a public hospital. On the ground floor there were consultation rooms and offices, recreation rooms for patients, and a convalescent dining-room, as well as corresponding departments in the main building. On the floor above there were a number of patients' rooms, provided with bath and lavatory, and in some cases with sitting-room adjoining; others contained two or four beds. On the floor above this similar provision was made for maternity and gynaecological cases, and on the top floor were operating theatres and sterilizing rooms.

The advantages of this scheme to the patients were that numbers of upper and middle class people would be able to obtain institutional accommodation and treatment of the same high standard as that provided for the necessitous poor. To the hospital itself it would bring the advantage that the special departments could be more fully and continuously used than was the case at the present time, while overhead charges for general administration would be shared proportionately increased, and such charges could be shared to a proper extent by the paying department. A hospital he had recently inspected included a separate building in which there was accommodation for a hundred paying patients. This was built and equipped by a generous donor who had himself been a paying patient in the public wards. The new block was managed by the general hospital, and yielded a profit of £10,000 a year, which was available for the charitable operations of the institution. Again, there were advantages to members of the hospital staffs, who would be able to have a certain number of their patients in the paying department, thereby saving themselves time and journeys.

Improvements in Existing Public Hospitals.
Mr. WARRING then made some suggestions for the improvement of the ordinary public hospital. He thought, in the first place, that there ought to be more maternity accommodation. He was told by an eminent obstetrician that the mortality in connexion with maternity was now little different from that which obtained in pre-septic days; no doubt insufficient accommodation contributed to this result. It was desirable also to limit the routine dispensing of medicines and drugs, which was often on too liberal a scale. Another deficiency of the ordinary hospital was lack of accommodation for dental cases. Then the buildings themselves were often unsuitable. There was a widespread notion, not limited to the laity, that any comparatively decent hospital, whenever possible, should be converted into a satisfactory hospital of suitable size could be converted into a satisfactory hospital. Whenever possible hospital buildings should be specially erected for the purpose, and when they became antiquated they should be scrapped. It was a great mistake to patch up old buildings, and it might be wise to scrap every hospital building which had existed for fifty years. He suggested that the King's Fund, in association with the Royal Colleges, should set up a small consultative body to advise upon the building, reconstruction, and modernization of hospitals. In general hospitals there was not sufficient provision of small rooms for the seriously ill and the moribund. It would be an enormous advantage to members of the staff and also to patients if small rooms were provided. Another need was for some clinical laboratories in connexion with hospital wards or clinical units.

He advocated also the standardization of hospital equipment. There was too much tendency in all hospitals for every medical man to think that he was in a position to order

whatever equipment he required for his own particular fads. The same thing applied to the sterilization arrangements. If the hospitals would work on some simple standard plan they would get their plant at half the cost. The accommodation for the nursing staff was often defective. He did not approve of the nursing staff being housed in the attics or any ill-adapted part of the hospital. The nursing staff should have its own special block. Again, the administration of many hospitals was unsatisfactory, due to the multifarious duties of the administrator; the work of the director of a hospital should be separated from that of the head of the appeal department. Medical men as a rule did not make the best administrators of a hospital.

As for private hospitals, many of these were originally private dwellings in which no reconstruction had been carried out and no provision made for scientific investigation. He showed plans of an ideal private hospital, very much on the lines of the private block already described, with special consulting rooms for physicians and surgeons on the ground floor, accommodation for medical and surgical cases on the first floor, for maternity cases on the second, and for the operating theatres and their accessories on the third. It had always seemed to him very curious that English people when on holiday took a suite of rooms at the best hotel they could find, but when they were ill they were prepared as a rule to go to a third or fourth rate lodging-house in a back street.

Lord Knutsford's Criticisms.

Lord Knutsford, who approved of Mr. Waring's suggestion regarding the additional provision for maternity cases, said it was a scandal that in a hospital with a thousand beds only ten or fifteen should be set apart for "the natural disease of having babies." He believed that the dental department should be in a separate hospital. Standardization of hospital equipment was of all things most abhorrent to him; it always meant the stereotyping of the second-rate. The greatest check upon extravagance would be to require that before a medical man could order anything he had got to get three of his colleagues to agree. This would not be difficult, with amenable juniors. He did not see why a paying hospital should be mixed up with a voluntary hospital at all. His idea of a paying hospital was a really well built hospital, with a resident surgeon, and, conspicuously displayed in the entrance hall, a scale of inclusive charges, so that a patient who had to undergo a particular operation would know exactly what it would cost him. He derided the idea that hospital buildings should be periodically scrapped. If they followed changes in architectural fashions the London Hospital might have been entirely rebuilt three or four times, and structurally be out of date even now.

SURGICAL SHOCK.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, on May 4th, with the President (Professor HENRY BRIDGES) in the chair, a paper was read by Mr. JOHN D. MALCOLM on "Surgical shock." He said that surgical shock was attributed to an irritation of sensory nerves. The expression was not intended to indicate an association with surgery so much as a freedom from haemorrhage, crushing of tissues, septic infections, and other complications which often accompanied accidents. Moreover, an accidental uncomplicated stimulation of sensory nerves frequently caused an instantaneous development of all the symptoms of profound shock, whereas during a surgical operation the changes occurred gradually, and their relationship to each other might be defined. The essential sameness of an immediately and a gradually developed shock was assumed. The condition was now rare in surgical work, but the following facts might still be noted if carefully looked for. During a severe operation the heart's action might hasten early, in which case an important feature of developing shock was not recognizable; but in a fair number of prolonged operations, when the patient's heart muscle was strong, the pulse rate for a time hardly quickened. In these circumstances there was at first a full radial pulse, which gradually diminished and might disappear completely whilst the carotid remained forceful and slow. After a time the cardiac action hastened, the pulse became feeble or disappeared everywhere, and the blood pressure fell. The tissues were now absolutely blanched, and medium-sized vessels did not bleed when divided. The vascular system became as depleted as in a case of severe haemorrhage, although little blood might have been shed. The tempera-

ture fell very low, and perspiration was profuse. Recovery used to be slow and to cause much anxiety, but since fluids had been freely administered a return to normal conditions was generally rapid. The improvement thus brought about offered a proof that as shock developed fluid was removed from the body. The clinical evidence was regarded as conclusive that stimulation of sensory nerves caused a persistent vascular contraction in spite of the rise of blood pressure in the large arteries which was created by their contraction and by an augmented cardiac force. But contracted arteries necessarily held less fluid than full-sized vessels, therefore fluid must leave them as they contracted. The escape of fluid was accompanied by a fall of blood pressure, which was compared with the loss of pressure that occurred in any piece of machinery actuated by hydraulic force when a leakage took place.

The effects of haemorrhage during a developing shock were considered. It was shown that in shock as in haemorrhage fluids were transferred within the body so as to correct abnormal relative pressures. This did not necessarily involve a filtration such as occurred through a dead membrane under pressure, and it was not considered inconsistent with Professor Leonard Hill's teaching that imbibition of fluids by living animal cells was a vital process. When the vessels contracted fluid must leave them; it must be taken into the tissues; the necessary imbibition was controlled by the nerves in accordance with the needs of the body. Mention was made of cases in which the sweat glands could not be induced to act, in which, therefore, fluid did not leave the body, and in which the clinical symptoms of surgical shock did not exist. Evidence was quoted that it was difficult to introduce fluids into and retain them in the vessels when shock was severe and profound. This difficulty, and the facility of absorption of fluids during convalescence, were easily understood if the vessels were tensely contracted when shock was fully developed and relaxed as recovery took place. The facts were not readily reconcilable with the teaching that some part of the vascular system dilated during shock, and therefore contracted during recovery. The chief object of the paper was to insist upon the view that a state of shock did arise from an uncomplicated stimulation of sensory nerves. It was considered of supreme importance for the understanding of many surgical developments that shock thus induced should be clearly differentiated from similar conditions which, however exactly they might simulate shock, were produced in other ways. The conditions of spinal anaesthesia were considered an absolute proof that shock was a reaction to nerve stimulation. By anaesthetizing the spinal cord a development of shock from stimulation of nerves arising below the blocked portion of the cord was absolutely prevented.

Dr. LATHROP SMITH said that the paper was very valuable because it embodied the experience of one who had had a great many operation cases and in the early days had seen more of shock than was customarily seen now; in his (the speaker's) own early experience cases of shock were very frequent, but by degrees they diminished in number until they became almost unknown. It was the experience of most surgeons, he thought, that cases of shock were remediable and preventable. Many early cases of supposed shock were not shock at all, but simply prolonged anaesthesia. The length of time taken by the operation had a great deal to do with the occurrence of shock. If the operation was finished within an hour cases of shock were unlikely. The amount of blood lost was a very important factor. He was accustomed to tell his students that the likelihood of shock was greatly reduced in cases in which the intestines were not seen at all in the course of the operation. A very important precaution was to maintain the patient's warmth during the operation, and this he had done by using two pans about 3 ft. long, closed in and filled with water at a temperature of 110° or 120°, and covered with a blanket.

Dr. MALCOLM DONALDSON said that in general his experience supported Mr. Malcolm's conclusions, but he was not quite convinced by his argument that a contracted vessel must lose fluid more quickly than a dilated one. (Mr. MALCOLM said that his statement was that a contracted vessel must contain less fluid than an uncontracted one, and therefore fluid must leave it as it contracted.)

Mr. GORDON LEEKER, who thought that Mr. Malcolm had proved his hypothesis, mentioned the extreme difficulty of separating shock from shock plus haemorrhage. He would be glad of any suggestion for distinguishing between these two conditions, for, of course, a good deal of difference in treatment depended upon such distinction.

Dr. A. E. GILES pointed out that if the arteries were contracted it simply meant that less fluid was passing through them, not that there was less fluid in the system generally. The fluid might have passed into the dilated capillary area, and so be not lost to the body but temporarily lost from the arteries. He spoke with great diffidence on the subject of shock because he had seen so little of it. He came to the conclusion many years ago that deaths ascribed to shock were very often due really to haemorrhage or septic poisoning, and that pure shock after operation was very rare; all that he had seen of surgery since had rather confirmed him in that view. Even in removing a very large ovarian cyst he had never observed anything suggestive of shock, and he believed that any such sequel must be very infrequent if the operation was done with reasonable rapidity.

The PRESIDENT said that the Section was greatly indebted to Mr. Malcolm for the way he had pursued this problem. He emphasized the difficulties of the subject and the need for further scientific work upon it. He believed that the leakage of fluid must pass to the capillaries.

Mr. MALCOLM, in replying, said that he did not think that the largeness of a tumour removed was the cause of shock: he agreed with Dr. Giles that such tumours could be removed without shock. Of course, time was an important factor, and the amount of blood lost was also important. Haemorrhage and shock were two quite different conditions in his mind, although they both created the same condition of starvation of the tissues. It was asked, why not give fluids? But if recent medical research was right, it was out of the question while the vessels were contracted for them to take up fluids. Undoubtedly the procedure was useful when the vessels relaxed. It had been suggested that contraction of the vessels was a means of self-preservation, but the cause of the mischief could not very well be a factor in preservation, and he did not think that in any condition of developing shock the contraction of the vessels indicated this. One absolute distinction between shock and haemorrhage was that in shock there was concentrated blood, and in haemorrhage diluted blood. He believed that this fact of concentration of the blood had been proved by the Special Investigation Committee of the Medical Research Council. As to the escape of the fluid, he believed that this was effected by passing on to the capillaries.

OPHTHALMIC PENSIONERS.

A MEETING of the Sheffield Medico-Chirurgical Society was held in the Medical Library of Sheffield University on April 27th, with Dr. GODFREY CARTER, the President, in the chair, when Mr. HERBERT CAIGER, Chairman of the Sheffield Division of the British Medical Association, read a paper entitled "Ophthalmic pensioners: some points of interest to the general practitioner." Out of 700 cases there were 7 cases of total blindness, about 50 cases of loss of useful vision in one eye, 53 cases of removal of one eye, and only one case of sympathetic inflammation; in this case the injured eye was not removed till twelve weeks after being wounded. Penetrating septic wounds of the eye, with lodgement of a foreign body, had been very numerous in the war; but, thanks to the careful work done in hospitals overseas, sympathetic cases had been very rare. Most cases of loss of vision in one eye had been caused by "concussion changes." These might be compared to the fractures in bones due to indirect violence. Bullets passing through the bones below or at the side of the orbit, without touching the eye, caused haemorrhages or ruptures in the choroid or retina. The macular region was specially affected by these concussion changes. They had been specially studied by Lagrange, who attributed them to violent oscillatory waves transmitted to the fatty contents of the orbit, almost fluid at the body temperature.

It was specially important to examine for errors of refraction in three groups of pensioners: (1) Men who had lost the sight of one eye were, as a rule, obsessed with the idea that any defect of vision that troubled them must be due to "one eye having to do the work of two." In most cases any defect of vision (except the inevitable loss of field on the affected side) was due to error of refraction in the uninjured eye, and could be remedied by glasses. (2) Cases of headache following head injuries: here headaches, very possibly due to eyestrain, were liable to be put down to the head injury, by the doctor as well as by the patient. (3) Neurasthenic cases: such symptoms as depression, or mental confusion, as well as

headache, might be due entirely or in part to eyestrain from astigmatism, etc.

One interesting case of functional blindness was described. The patient had been "blown up" by a shell explosion in 1914. He stated that he lost the sense of smell, taste, and sight, but that taste and smell were soon restored "by hypnotic treatment." More or less complete functional blindness, however, lasted for two and a half years, partial recovery being followed by relapse, especially if he was subjected to worry. In 1917 cure followed treatment by isolation in hospital, blistering, and other methods, including the sudden shock of a bucket of cold water thrown over him unexpectedly in a warm bath. He presented other neuro-pathic symptoms, such as tremor. Complete and lasting recovery followed.

Cases of malingering of every grade had been met with. There were at least 20 cases claiming that the defective sight of an amblyopic squinting eye was due to or aggravated by service. Three cases of conjunctivitis artefacta were described. In one of these deliberately produced abrasions of the cornea were an added feature. In another case the man's documents gave a record of "persistent chronic conjunctivitis liable to acute exacerbations," commencing in 1917 and lasting almost for five years. For three years he had enjoyed a pension of 60 per cent. or more. Minute observation revealed very fine foreign particles in the conjunctival sac; when kept under observation for an hour the acute redness of the eyes diminished greatly; then, after being left alone in a room for a moment, an "acute exacerbation" followed at once, with increased redness and profuse watering of the eyes. The nature of the irritant used was not ascertained.

Only one case had been seen where gassing appeared to have caused serious permanent damage to sight; in this case the whole of the left cornea was opaque, and the lower half of the right cornea; a visual iridectomy had been done above in the right eye, and vision with glasses was 6/24.

Some cases illustrating concussion changes were shown.

In discussing the paper, Mr. P. J. HAY referred to the valuable work done in the war by general practitioners who took up ophthalmic work overseas. Dr. E. F. SKINNER mentioned some cases of conjunctivitis artefacta in school-boys, induced by blowing slate-pencil dust in one another's eyes. Mr. A. CONNELL described a case of extensive rupture of the choroid due to indirect violence, which had occurred in civil practice. Dr. A. E. NASH, referring to functional blindness, pointed out that the cerebral cortex possessed the power of focussing conscious attention on any particular area of consciousness—for example, sight or hearing—or, on the other hand, of completely excluding it.

Mr. GEORGE WILKINSON demonstrated on the epidiascope an apparatus illustrating the resonance theory of hearing as applied to the cochlea.

Dr. GODFREY CARTER, the retiring President, congratulated the society on the valuable series of papers presented to it in the session now brought to a close.

PERHALATION METHOD OF ETHER ADMINISTRATION.

A MEETING of the Scottish Society of Anaesthetists was held on April 15th in the rooms of the Medico-Chirurgical Society, Aberdeen, with the President, Dr. JOHNSTON, in the chair, when Dr. OGSTON read a paper entitled "Notes on the administration of ether by the perhalation method." He pointed out that this system now replaced chloroform as the stock method for abdominal surgery, and that the standard which it had to meet was therefore a high one in respect of abdominal relaxation and quiet respiration. If the points referred to later were attended to there was no difficulty in reaching the required standard. To be effective as an inducing agent as much as 18 per cent. or more of ether vapour was necessary, whereas when given on the ordinary mask Hewitt and Syme had shown that not more than 14 per cent. was available. As much, or possibly more, ether was vaporized by expiration as by inspiration. By a simple device Dr. Ogston demonstrated to the audience that ether vapour did not rise in an appreciable quantity more than half an inch above the mask, whereas it was easily detected, by touch, smell, and sight, many inches below it. The apparatus used by him provided for the conservation of this ether vapour of expiration. It consisted of an ordinary Bellamy Gardner mask, upon which was erected a secondary frame composed of six uprights,

joined at their distal extremities by a metal ring; a towel pinned round the uprights furnished a cylinder, at the bottom of which the ether vapour collected. The aperture was as wide at the top as at the bottom, so that all the gauze was available for the reception of drops of ether. Personally, he preferred to keep the head in the mesial position even during deep anaesthesia, so that the apparatus was suitable both for induction and maintenance. Some twelve to sixteen layers of gauze were used on the mask itself and great care exercised as to the fit between face and facepiece. Another point on which he laid great emphasis was the even distribution of the ether. If all drops fell in one spot freezing took place, and the ether percentage was lowered; dropping must, of course, be continuous. In favourable cases induction took six to ten minutes. With the use of the cylinder the temperature in front of the mask did not fall below 50° or 60°. After anaesthesia is established and less ether is being used the temperature within the cylinder rises to 70° or over. The economy of ether was such that overdosage was quite possible. No doubt there was also some concentration of carbon dioxide, but rarely of such a degree as to do any harm. Occasionally one saw shallow breathing and duskeness which might be attributable to this cause. Such symptoms passed away at once if the mask was withdrawn for a few respirations and was turned upside down to empty the gaseous contents of the cylinder. A free airway was essential. He believed greatly in Hewitt's airway; when necessary he even put a gag or prop between the teeth before beginning induction. He believed in going very slowly at first; this really saves time in the end, as it caused less mucous and respiratory embarrassment. In order to secure this result he often started with the apparatus upside down, having the aperture of the cone adapted to the face and dropping the ether upon the inside of the mask. Before the operation was started he abolished the corneal reflex and obtained medium dilatation of the pupils. Later, he allowed the corneal reflex to reappear. He regarded sighing as rather a favourable sign, showing sufficiently deep anaesthesia; moaning indicated too deep a level of anaesthesia.

Dr. J. S. Ross thought the method really provided for induction of even powerful subjects by ether alone. Frankly, he personally used a little chloroform—not more than a drachm—during the induction stage, but the lecturer evidently did not find this necessary.

Dr. LAMM thought induction by ether alone was rather slow, and would like to hear some more details of Dr. Ogston's experiences in this respect. He did not agree with Dr. Ogston as to the meaning of moaning, which he considered indicated a light, not a deep anaesthesia.

Dr. BARRAS doubted whether corneal reflex was very valuable if morphine had been given. Dr. FAIRLIE preferred the lateral posture for the head when deep anaesthesia had been obtained; otherwise he agreed with most of Dr. Ogston's views.

Dr. FREW was interested in the simple design of Dr. Ogston's apparatus. He had tried a towel in front of the mask to condense the vapour, but without much success, and had adopted the apparatus, described some time ago in the *BRITISH MEDICAL JOURNAL* by PICTON, which had the advantage of maintaining a somewhat higher temperature of the inspired air than did the ordinary method.

Mr. G. H. COLT, speaking as a visitor, wished to thank the society for inviting a surgeon to attend, a course which might be to the mutual advantage of anaesthetist and surgeon. He drew attention to the difference between open ether given by the expert to a prepared patient, and by the novice to a patient who had not had morphine and atropine; the latter condition was one of the drawbacks of the method in outpatient practice, notably in the reduction of fractures. The expert anaesthetist rendered the performance of difficult operations comparatively easy. Some form of muscle tonometer might be an advantage during the different stages of an operation, especially for teaching purposes.

The PRESIDENT thanked Dr. Ogston for his valuable contribution and gave personal testimony to the great success of the method. He believed that to those who had not made use of some such assistance to the ordinary open ether method, the facility with which Dr. Ogston induced by the use of his method would be a great surprise.

Dr. OGSTON, in replying to questions, stated that he used 1½ oz. to 2 oz. of ether for the induction and completed the first half-hour, as a rule, by 4 oz., including the induction stage. Those quantities were for average cases. In debilitated cases 1 oz. may suffice for induction, while in robust alcoholics as much as 2 or 3 oz. may be required.

Nitrous Oxide and Oxygen.

Dr. HOLME HENDERSON read a paper entitled "Some considerations on gas and oxygen." He said that this combination had as yet been little used for prolonged anaesthesia on this side of the Atlantic, and few of us had sufficiently long experience to enable us to speak didactically. From America, however, we had such statistics as those of Lakeside Hospital, Cleveland, in which Teter and his assistants had given 34,964 administrations without a fatality. Statistics, as a rule, had value to a coroner only; they left out the personal factor. The general public believed that of all anaesthetics nitrous oxide and oxygen had the smallest mortality, but this belief was not necessarily correct. As regards its administration, there could be no question but that long administration with the older apparatus often led to very alarming symptoms, such as pallor and faint breathing, which might or might not be due to the conditions now recognized as acapnia. The modern apparatus provided for complete control of the flow of gases and of their relative proportions, and also for rebreathing. This had made an immense difference, and by the use of such plant beautiful results could be obtained. There was perhaps in America, however, a tendency to place too much reliance upon mere mechanical perfection. One read accounts of a single lady, not possessed of a medical qualification, looking after six patients to whose faces the mask had been attached, but one must receive such stories with caution. At the same time he did not wish to throw any doubt upon the accuracy of American figures. Evidently their results were obtained with a degree of brilliance which did not appear to be easily attained in this country. One could only suppose that there were some factors different in the two countries. He thought the American subject was more open to the power of suggestion, and possibly less addicted to the use of alcohol, which made him a better subject for anaesthesia. He thought we should be wise not to spoil the case for nitrous oxide and oxygen by overrating its claims or underestimating its possible dangers. The main object of his paper was to urge members of the society to record their own impressions of the method, and in doing so to indicate their views upon the most appropriate drugs and dosage for preliminary medication, and the combination of other adjuvant anaesthetics during the operation. Such aids to nitrous oxide and oxygen were undoubtedly necessary, as the anaesthesia by the gases themselves was of a very light degree. No account of administrations was of any value unless these helps were clearly recorded. So far as the general public was concerned, he thought they should be made to grasp clearly this point, that while nitrous oxide and oxygen was the safest of all anaesthetics in the hands of an expert in the technique of its administration, it was perhaps the most unsafe in the hands of the inexperienced, and it should, therefore, never be administered except by an anaesthetist specially trained in its use. It was interesting to learn that the first gas-oxygen administrator at the Lakeside Hospital had to become proficient in anaesthetizing dogs by the method before being allowed to use it on his fellow men.

Coming to his own personal experience, he found that it was no use working with anything but a first-class machine, which gave real control of the two gases and of any auxiliary anaesthetics. The one that he used was as versatile as any: it was the Gallagher Model, U.S. Army. Previously, he used a small model U.S.A. Gwathmey machine, and though quite pleased with it he saw that the other had some additional advantages. He was sure that the time was not far off when the anaesthetist dare not run the risk of having no means to give gas-oxygen when called on, and he thought, therefore, it was wise to have a spare apparatus in reserve. It was necessary to understand every detail of the mechanism one was using. As to the class of case, he had used it for all branches of surgery, even in eye work—extractions, iridectomies, etc.—and he had found it very satisfactory. In abdominal work, undoubtedly, it was the severely toxic cases in which the advantages of the method were most marked. From experience in such difficult cases as gall-bladder operations and removal of the prostate, he had formed the conclusion that any case might be done under gas oxygen if it were absolutely necessary.

The PRESIDENT thanked Dr. Henderson for a most interesting paper, and said that he considered the time at the disposal of the meeting was too brief for an adequate discussion. It was therefore resolved that a summary of the paper should be circulated to the members and the discussion put upon the agenda for the autumn meeting.

Reviews.

INJURIES OF THE HEAD.

THE death of the author unhappily coincided with the publication of Professor Duret's life-work on cranio-cerebral injuries. For fifty years Professor Duret had proceeded with his investigations, amassing clinical material, performing experiments, and publishing from time to time papers by his own hand or by those of his assistants. The final reviewing of a life-work of acute observation was greatly embarrassed by the capture of Lille and the cutting off of the author from the civilized world. In spite of this handicap, which the author did not unduly stress, he succeeded in producing one of the most remarkable works of our time. His book, *Traumatismes cranio-cérébraux*,¹ consists of two volumes, the first of which has already been noticed in our columns (June 19th, 1920, p. 830); it was concerned with the mechanism of cranial fractures, with their anatomy, and their gross results.

The second volume is divided into two parts. The first deals with cerebro-spinal fluid in reference to cerebral injury, the second with the pathogenesis, diagnosis, and treatment of cerebral commotion. At first glance it might be thought that the part played by the cerebro-spinal fluid in injuries to the head is a subject briefly to be dismissed. The influence of this fluid on cerebral injuries is, however, one of the late Professor Duret's most notable discoveries. He regards cerebro-spinal shock as the most important factor in cerebral commotion; he believes that it is through the agency of this fluid that the forces of injury applied, say, to the vertex are transported to the vital structures in the posterior cranial fossa. His experiments of 1878 on dogs led him to this conclusion, for he found it possible to produce severe lesions, from punctate hæmorrhage to cerebral bursts of the floor of the fourth ventricle, by injuries to the top of the animal's head. These posterior fossa lesions, which Koehler classified as the "Duret'schen Läsionen," he was later able to find in man. Several chromographe plates illustrate these points. It is easy to recognize here the contrecoup injuries of so many authors. Duret believed that the cerebro-spinal fluid had an important regulating action within the skull, and there is much to be said for this view.

The subject of cerebral compression receives long and skilful attention at his hand. Duret favoured the theory of a vasomotor sympathetic action on the cerebral vessels, but was unable to produce incontrovertible evidence on this point. The work of Koehler, Cushing, and Leonard Hill receives adequate exposition, as, indeed, does that of most authorities. Innumerable histories, not only of the author's own cases, but very largely those gathered from the world's literature, are given, together with a profusion of illustrations of the injuries found at operation, or more often at necropsy.

The diagnosis, prognosis, and treatment of commotion in its various forms is thoroughly discussed. Duret believed in lumbar puncture, not only to assist in diagnosis and to relieve hypertension, but to lower the intracranial toxæmia of hæmic origin which he thought played a part. He also believed in the value of ice applied to the head, a custom which was a little time ago considered old-fashioned, but is likely to be revived. His sections on the operative treatment of cranial injuries are very sound indeed, and he did well to call attention to the fact that hæmorrhages into the white matter and into the ventricles may be traumatic in origin. Duret was no doubt right in thinking that concussion in men is the resultant of forces acting on many structures, diverse, but infinitely valuable in function. Space and time have had no curtailing influence, and the views of writers are given fully, together with their most important diagrams. This greatly enhances the value of the work for purposes of reference, a value which is greatly diminished by the absence of an index. The analysis given beneath each chapter heading and the "Table des matières" are, of course, totally inadequate advertisements of one's wares. It is a thousand pities that we have nothing more orderly than these, because these volumes are encyclopædic. To them surgeons are going to turn as to a treasure house for many years to come. The paths to this house are obscured by weeds.

¹ *Traumatismes cranio-cérébraux*. By Professor H. Duret of Lille. Paris: Félix Alcan. Tome II, Parts I and II. (Roy. 8vo, pp. 1357; 272 figures. Fr. 50 the two vols.)

FOTHERGILL'S "MIDWIFERY."

THE appearance of the fifth edition of Professor W. E. FOTHERGILL'S *Manual of Midwifery*² carries the reviewer back to the end of last century when, as a student, he studied the first edition with the aid of tobacco and the midnight oil. The book was then regarded as being an epitome of the late Sir A. R. Simpson's teaching, and for that reason, amongst others, was popular in Edinburgh at that date. Its essential excellence has, however, made it popular in other schools as well, and it is gratifying to see that it retains so much vitality. The book is still the same in all essential characters, and the reviewer cannot wish more for it than that the present generation of students may find it as satisfactory as did their predecessors. There are, however, nowadays other and newer books competing for the favour of the student of midwifery, and one cannot but feel that Professor Fothergill's book might have been improved by an attempt to present the subject on rather more modern lines. In his preface Professor Fothergill says that in revising the book he has been "impressed by the trifling nature of the advances made in the ancient art of midwifery." The reviewer confesses to feeling similarly impressed with the trifling nature of the advances and changes made in this book since the appearance of the first edition in 1896. He observed that no criticism is offered as to the soundness or modernity of the teaching (except as indicated below), but it smacks a little of the archaïe to see the old terms "reflexa" and "scrotina" still applied to the decidua; is it not waste of space in a student's textbook to explain the misconception which led to the establishment of that nomenclature by John and William Hunter? This is only one example of what is meant. Another point which the reviewer noticed is that occasionally the writer's meaning is obscured by tautology. What, for example, is to be made of the following: "It is desirable to measure the patient's waist over the skin. This measurement is usually less than the measurement taken over the clothes at the same place. The measurement over the clothes should really be a little larger than that taken over the skin"? Statements like these make one feel that the revision of the book has been somewhat perfunctory.

Professor Fothergill says that "the spread of Caesarean section has been accompanied by some loss of interest in the abnormalities of the bony pelvis, the mechanisms characteristic of them, and the 'obstetric' methods of dealing with them." This, if true—and we fear that to some extent it is true—is deplorable; it is disappointing; therefore, to find Professor Fothergill dismissing the important subjects of the mechanism and treatment of labour in a flat pelvis in rather less than two pages. Furthermore, he recommends the early application of forceps after the dilatation of the cervix is complete, "as this saves exhaustion to the mother and risk to the child, and causes no danger if extraction is not hurried." There is no suggestion in this of the enormous value of giving the head plenty of time to mould. We wonder if this represents the deliberate teaching of the Manchester school of obstetrics. It is true that the recent report of St. Mary's Hospital presented positively startling statistics in regard to the treatment of contracted pelvis, the great majority being treated by Caesarean section, while the forceps operation had been relegated to a position of very diminished importance. Unfortunately, the data in that report were hardly full enough to enable a proper judgement to be formed, and one must recognize the great frequency of bad degrees of rickets in Manchester. But it is just possible that this enthusiasm for Caesarean section may prove to be a passing phase, and, if so, one feels doubtful as to the wisdom of inculcating it as accepted teaching in a book of this sort.

A TEXTBOOK OF PATHOLOGY.

THE seventh edition of the *Textbook of Pathology*,³ by Drs. ALFRED STENGEL and HERBERT FOX of Philadelphia, has been extensively revised: new sections have been added and some sections have been rewritten. The book, which is of over 1100 pages, endeavours to be comprehensive, and deals not only with the morbid anatomy and histology of disease, but also includes chapters on bacteria, methods of transmission of disease, and animal parasites. It also includes the discussion

² *Manual of Midwifery*. By W. E. Fothergill, M.A., R.Sc., M.D., Professor of Obstetrics and Gynaecology, Victoria University of Manchester. Fifth edition. Edinburgh: W. Green and Son, Ltd., 1922. (Cr. 8vo, pp. 488; 103 figures, one double coloured plate. 10s. net.)
³ *A Textbook of Pathology*. By Alfred Stengel, M.D., Sc.D., and Herbert Fox, M.D. Seventh edition, reset. Philadelphia and London: W. B. Saunders Company, Ltd., 1921. (Roy. 8vo, pp. 1111; 509 figures, 15 plates. 42s. net.)

of the anatomical lesions associated with diseases of the nervous system, the eye, the skin, and the ear. Gout, diabetes, and acidosis are only lightly touched upon in a short chapter headed "Disorders of nutrition and metabolism," in which also "feret," "beri-beri," and "pellagra" are included. The two latter conditions are stated to be due to the absence of substances to which Funk has given the name "vitamins." This, except for one line at the beginning of the chapter, is the only reference made to substances which recent investigations have shown possess considerable importance. They are not even mentioned in discussing the etiology of rickets. The book, however, hardly touches throughout on the chemical side of disease.

One of the sections rewritten is that on nephritis; the classification adopted is, it is stated, based on clinical grounds, but the account leaves the reader with a rather bewildered impression. A short account of modern views on the anatomy and physiology of the organ is given, in which the authors state that the glomerulus secretes a dilute plasma, and that the function of the tubules is reabsorption. The description leaves the question of any secretory activity of the tubular epithelium entirely indefinite; in fact, it is hardly mentioned. Great faith appears to be placed in the picrosulphonic-phthalcin test to determine whether a renal lesion is present or not. The basis of classification is that tubular changes are characterized by pronounced albuminuria, low blood pressure, and oedema, which may become chronic and form the large white kidney, while glomerular changes are characterized by little albumin, high blood pressure, and uraemia. This position is a difficult one from which to form an understandable classification, for cases of nephritis at times are met with which can be observed to pass from one group to the other.

The section on influenza also has been rewritten. Pfeiffer's bacillus is considered, on present evidence, to be the most likely cause of the infection. The difficulties attending the culture of this micro-organism are rightly insisted on as an important factor in the value of evidence of its prevalence in any particular outbreak. Great stress is laid upon the bacillus as the prevalent organism in a type of chronic bronchitis which tends to form bronchiectatic cavities; this contention is based on work done by the authors. They also maintain that a vaccine of the organism has curative value in chronic cases of this nature. They, however, allow that such lung conditions are almost always accompanied by other infective organisms, so that the specificity of the relation between Pfeiffer's bacillus and the lesions is not proved. They state that influenza is a "toxaemia" in which the "virus" spreads rapidly through the body, and not a simple upper respiratory tract infection; they describe lesions in many other parts of the body, but fail to explain why the usual view that the "toxaemia" or general clinical reaction is due to an infection of the upper respiratory tract as primary cause does not afford a satisfactory explanation of the pathology of the condition. It is also not clear what is implied in the use of the term "virus" in such a condition, whether it refers to the organism itself or its toxic products; a search in Chapter VIII, on "Bacteria, their nature and action," does not remove the difficulty. In this chapter Ehrlich's side-chain theory is described at length; it is held to explain the phenomena of immunity; but this is a position difficult to maintain at the present day.

From the above examples it will be seen that controversial matter is easy to find in the volume, and that the views given are not always easy to follow or necessarily those most widely held by pathologists in general.

The book is profusely illustrated, but many of the illustrations are far from satisfactory; certain of the photographic reproductions are only decipherable with much difficulty, and almost all the illustrations suffer from the absence of any detailed description of what they represent, or any lettering to indicate the important points intended to be shown. One feature of very doubtful value is the modification of illustrations from other textbooks, especially when such illustrations were originally drawn from actual specimens. The absence of any form of authors' index or any system of references diminishes the value of the book as a work of reference. There is, however, a fairly complete subject index which enables the authors' views to be arrived at. Regarded as a student's textbook, the attempt to include an account, often involving much detail, of all sides of pathology in a single volume must lead to the inclusion of a large number of statements open to criticism, and to a volume somewhat indigestible for the average reader.

PUBLIC HEALTH CHEMICAL ANALYSIS.

There are already so many standard works on chemical analysis suitable to the needs of public health officers that there hardly seems room for another volume on the subject unless it has an outstanding individuality, and this cannot be said to characterize *Public Health Chemical Analysis*, by FREDERICK and FORSTER. It is not quite clear for whom the work is intended: if for public analysts, it does not contain enough information; and if for medical officers of health, who do not do much actual analysis, though they are expected to be able to interpret results, it is not sufficiently explanatory and presumes more knowledge in the reader than most of them possess. Almost on the first page the authors, when describing the manner of using the chemical balance, say, "the balance must be at rest during the moving of weights or objects on the pans." This would be understood by a trained student, but one who is untrained should be told that "the balance beam must be removed from the agate knife edges during the moving of weights," etc.

The best portion of the book is that which deals with the collection of samples of air and of water, and in this respect medical officers of health may find it of value. Haldane's apparatus for the estimation of carbon dioxide in air is recommended in preference to Pettenkofer's or the Lunge-Zeekendorf method. The description of Haldane's apparatus is clear and concise. The directions for the collection of water samples are those which are usually sent out from public health laboratories, and the particulars it is recommended the collector should be asked to submit are fairly complete. Half a dozen pages are devoted to sewage, trade waste, and effluents, and there are chapters dealing with milk, butter, bread, and other foodstuffs. The illustrations are carefully selected, and help in elucidating the text, while the tables and formulae given in the appendix will no doubt be found useful.

A NEW REACTION FOR SYPHILIS.

Since the introduction of the Wassermann reaction for the detection of syphilis many other so-called colloidal reactions have been introduced, with special reference to the examination of the cerebro-spinal fluid in cases in which syphilitic disease is suspected in the central nervous system. Of these the colloidal gold reaction of Lange, the gum-mastic test of Emmanuël, and the Berlin-blue test (Kirchberg) are the best known. These are described with some detail in a book² which has newly appeared in Paris. The imperfections of various methods are pointed out in it, but the main purpose of the authors, MM. GUILLAIN, LAROCHE, and LEEHELLE, is to urge the importance and infallibility of their own similar test with colloidal benzoïn. The details for carrying it out and evidence of its value clinically are set out at length. If it should prove to be what they state, observers will be provided with a simple and trustworthy means of diagnosis. In this country no doubt a body of investigators would have been content to publish their results and anticipations in a paper read before some medical society, and would hardly have considered a whole book (albeit not a big one) necessary for the purpose.

NOTES ON BOOKS.

IN *The Clinical Examination of Surgical Cases*¹ Mr. J. REXFREW WHITE, of Dunedin, New Zealand, outlines in tabular form a series of systematic methods for the examination of different types of surgical cases. The book is difficult and depressing, if not impossible, to read—in the study—but it will be of value to the medical student at the bedside by helping him to train himself in habits of careful and systematic examination of cases and case-taking. As hospital records suffer greatly from the lack of uniformity in the methods by which they are kept such a volume as this might also be of considerable value in serving as a basis for the systematization of case records. The author gives sixty-seven different tables of methods of investigation in different types of surgical cases, based upon his simple general method. The volume may be commended to teachers of clinical surgery.

NATIONAL COUNCIL FOR MENTAL HYGIENE.

A MEETING was held at the house of the Royal Society of Medicine on May 4th in connexion with the formation of a National Council for Mental Hygiene. Sir Courtauld Thomson, K.B.E., C.B., was in the chair, and there was a very large attendance.

The CHAIRMAN said that the platform was fortunate in having upon it so able an exponent of the views of the promoters of the Council as the President of the Royal College of Physicians (Sir Humphry Rolleston). A most sympathetic message had been received from the National Council of Mental Hygiene of America, and he trusted one of the results of that day's proceedings would be that Great Britain for the first time would be able to take her proper place in the international conferences on this subject. The Minister of Health had assured him of his sympathy and support.

Aims of the Movement.

The objects of the National Council, continued Sir Courtauld Thomson, were for the benefit of the whole country; all the skill, devotion, and energy of the medical profession would be of little avail without the whole-hearted support of the general body of the public. Laymen on the Council might relieve their medical and scientific colleagues of much of the work in connexion with organization and propaganda. He made an earnest appeal for the support of laymen, to whom the institution of this Council offered an opportunity for co-operating with the medical profession in helping forward the health and mental soundness of the nation.

Sir HUMPHRY ROLLESTON then explained in more detail the aims of the movement. After a reference to the present-day emphasis upon preventive medicine and to the amount of careful study which was being directed to the detection of the early symptoms of functional disorder, he pointed out the difference between bodily and nervous derangement. The man whose lungs or stomach were not up to the mark was still able to take his part in the work of the world, whereas the man who suffered from mental disorder, however slight, was to a much greater extent incapacitated. It was true that much had already been done in the direction of study of mental hygiene, but as compared with America, where they seemed to have a special genius for combining for action, the workers in this country on the subject had been less successful. The American Council of Mental Hygiene, founded in 1908, had done much good work; in 1918 a similar council was started in Canada, and in December, 1920, the French League of Mental Hygiene was inaugurated. It was important that a National Council on the same lines could be called into being in this country to confer with the national Councils, pool and disseminate the information thus obtained. In the work of preserving healthy minds in healthy bodies there was a crying need for helpers in other branches than those of medicine. The objects of the proposed British National Council would include organized co-operation with societies and associations engaged in promoting the study of mental disorders, the welfare of the insane, the various aspects of mental deficiency, and the problems of industrial psychology. The etiology of minor mental disorders, which were multiple and included heredity, environment, the influence of alcohol, syphilis, and the poisons met with in trades, such as lead, would be studied. The somewhat neglected subject of mental hygiene would be advocated for a more prominent place in the medical curriculum. Assistance would be given towards the establishment of psychological clinics at the mental hospitals for the treatment of early cases of mental and nervous disorders. A judicious propaganda would be carried out, putting forward the principles underlying mental health and disease, so that parents and teachers could realize that in their hands lay the making or marring of their children's and pupils' lives; and conferences would be held with the National Councils of other nations engaged in the same kinds of study.

Appointment of Council.

It was then unanimously agreed that a National Council for Mental Hygiene be formed, and on the proposition of Sir FREDERICK MOTT, seconded by Dr. FARQUHAR BUZZARD, Sir Courtauld Thomson was elected President. Lord SOUTHAMPTON proposed, and Lady DARWIN seconded, that the following should comprise the provisional committee, with authority to act for one year:

Sir Humphry Rolleston, President of the Royal College of Physicians of London; Sir Charles Sherrington, President of the Royal Society; Sir John Goodwin, Director-General, A.M.S.;

Sir George Newman, Chief Medical Officer, Ministry of Health; Sir Walter Fletcher, F.R.S., Secretary of the Medical Research Council; Dr. C. Hubert Bond, President of the British Medical Psychological Association; Dr. Bedford Pierce, President of the Section of Psychiatry of the Royal Society of Medicine; Professor George Robertson, President-elect of the British Medical Psychological Association; Dr. C. S. Myers, F.R.S., Director of the National Institute of Industrial Psychology; Sir Norman Moore, Dr. G. Ainsworth, Dr. Helen Boyle, Dr. Edwin Bramwell, Dr. Farquhar Buzzard, Sir Maurice Craig, Lord Dawson of Penn, Sir Bryan Donkin, Dr. Elliot Smith, F.R.S., Dr. Edwin Goodall, Dr. Henry Head, F.R.S., Dr. Crichton Miller, Sir Frederick Mott, F.R.S., Dr. W. H. R. Rivers, F.R.S., Dr. T. A. Ross, Dr. Tredgold, Dr. W. Worth.

Dr. H. B. BRACKENBURY doubted whether it was a wise thing to give the Committee power for as long as twelve months. He thought it very important also that the Council should have a representative character and not merely consist of eminent persons: societies which had been doing very good work along similar lines ought to be represented. Another speaker supported Dr. Brackenbury, and stated that too many of those proposed as members of the Committee had been responsible for what he termed "the bad old days." The atmosphere of the asylum was contrary to all their ideas of mental hygiene, and he would not have the Committee include any ex-superintendents of asylums.

The CHAIRMAN said that the names suggested were those mentioned in his recently published letter (BRITISH MEDICAL JOURNAL, April 1st, p. 538). He would be very glad to receive suggested names of persons whom the Committee might co-opt, but that meeting was not the proper place in which to discuss the merits of any particular individual. He hoped that there would be no hostile amendment. Dr. BRACKENBURY said that he had not the slightest intention of being hostile. The name he had in mind was that of Sir Leslie Scott, and he urged that the Solicitor-General should be put on the Committee straight away. This amendment was accepted, and it was also agreed that the Committee should be elected for six months. The CHAIRMAN remarked that the constitution of the Council had not yet been drawn up, but this would be done by an eminent firm of solicitors.

The Study of Mental Hygiene.

Dr. HENRY HEAD then delivered an address, in which he said that mental hygiene was the application to the life of the community of highly specialized scientific work, the results of which belonged to the most diverse categories of knowledge, and were gathered by workers in widely different fields. He pleaded for the co-ordination of the results of these multifarious activities in so far as they had a bearing on the mental health of the community. By mental hygiene was meant the maintenance of that state of health in which the human being could respond normally to the calls made upon him by daily life. It was as important to every man as the sanitation of his home. Every year we were learning more and more how inextricably mind and body were intermingled, even in the simplest mechanical acts. The evil effect of repression was one of the most important therapeutic lessons learned from the war. When he (the speaker) was working for the Royal Air Force, a pilot would be sent for examination because he was making bad landings, and would complain that although he always carried out the manoeuvre in the same way, it no longer came off with certainty: something had happened to destroy his skill. On closer investigation the cause of this loss of mechanical aptitude would be found on the physical or on the mental side: either he had some definite bodily ailment or was suffering from one of the many forms of anxiety. Moreover, this want of skill was usually accompanied by disturbed sleep and unpleasant dreams, which revealed the anxieties and fears so commonly accompanying what seemed to be a purely physical disturbance. The hard and fast line so commonly drawn between organic and functional conditions was grossly fallacious. No structural disease was free from its mental concomitants, and every mental state had its bodily equivalent. So-called "nerves" produced more individual and corporate misery than cancer. The condition was an evidence that something was wrong beneath the surface of the mental life, for subconscious processes were the link between the body and the mind. Dr. Head went on to say that had a knowledge of mental hygiene been more prevalent we should have been spared the crazy exhibition of suggestion to which the public had recently been exposed. We were advised, when the drain was obstructed, not to clear the effluent, but to say "Ça passe," in the hope that thereby the noxious effluvia would be dissipated. How widely the study of

mental hygiene entered into the life of the community was shown by recent research on industrial fatigue. Many years ago it was discovered, mainly by work in America, that the output in certain laborious occupations could be increased by eliminating unnecessary movements. This study had already grown enormously, but the aim of the investigator had changed. He was concerned no longer with the commercial aspect, but was now attempting to increase the efficiency of the worker by removing unnecessary causes of fatigue, and some striking results had been obtained, which Dr. Head described in detail. He considered that there was little doubt that much industrial unrest was due to the worry and fatigue induced by unsatisfactory working conditions, and while the State insisted on physical hygiene of the strictest order, they that day were pleading for an equivalent mental hygiene. True education was also, after all, but a branch of mental hygiene. If mental hygiene was of such universal importance in the conduct of daily life, how much more must knowledge of its laws be imperative for all who attempted to give advice in disease. Every medical man should be aware of the morbid mental states which were liable to accompany any organic disease or disturbance of function. He should be able at once to trace to their sources those ideas and feelings which occurred in persons who were not insane. Nurses also should have a knowledge of morbid psychology. Another class for whom knowledge of mental hygiene was profoundly important was ministers of religion, for depression in an early stage not uncommonly assumed a religious form. "The known is no longer terrible," said Dr. Head in conclusion, "but we dread and shudder before what we do not understand, particularly if it is something mental. We accept a physical disability, like a broken arm or an injured knee, and take our measures accordingly, but we are paralysed before things of the mind. Complete understanding abolishes fear and restores freedom of action. In the name of mental freedom I plead with you for the wide distribution of that most potent knowledge we know as mental hygiene."

Sir LESLIE SCOTT, the Solicitor-General, said that bad cases of mental deficiency were very easy to deal with. Institutional accommodation was effective and was the only satisfactory treatment. The difficult cases were those on the border line, such as cases in which conduct bordered on the criminal, and it was most essential here that the different bodies dealing with mental hygiene should be brought into close touch by some unifying organization. Persons who committed crimes because they were wrong mentally should be dealt with medically, and those who had to administer criminal justice should have the assistance of experts in such matters. There was in the public mind a tendency to fear that the medical officers of mental hospitals were overriding the rights of the lay public. That was a bogey; yet the fact that such a tendency existed should make it necessary to strengthen the lay side of such a council as was being brought into existence. If the doctors would welcome the co-operation of laymen and laywomen of sense it would have a great influence in bringing about a reaction of public feeling.

Sir JOHN GOODWIN spoke briefly of the matter from the point of view of the army. He insisted upon two points: the earliest possible detection and treatment of any mental aberration, and the careful and thorough treatment during convalescence of every case that had been through mental illness in order that recovery might be permanent and complete.

Sir MAURICE CRAIG said that for as long as he could remember this branch of medicine had worked under two important disabilities—the legal restrictions surrounding it, and ignorance on the part of the public as to what was meant by "mental disorder." The term "mental" always conveyed something uncanny, unhappy, and formidable to the lay mind. The wrong conceptions which were popular with regard to mental disorder must be eradicated, and the barrier which separated mind from body removed. Instruction would be one of the aims of this new council. It was well known that a very large amount of mental disorder could be prevented. It was bad medicine and poor economy to build vast institutions for the care of the mentally afflicted, when more money, time, and thought might be spent in preventing the bad conditions which caused the trouble. The public had awakened only recently to the fact that there were no real facilities for dealing with functional nervous disorders in this country at all, with the exception of such an institution as

the Lady Chichester Hospital, whose promoters deserved all credit. If anyone asked why one more council should be added to the many bodies already in existence, his reply would be that it might have made its appearance long since.

The proceedings then terminated. The address of the honorary secretary of the National Council is 51, Green Street, W.1.

NOTIFICATION OF VENEREAL DISEASE.

CONFERENCE AT THE LONDON GUILDHALL.

At the request of the Corporation of London, a conference was called at the Guildhall on May 3rd by the National Council for Combating Venereal Diseases to consider how infected persons could best be retained under treatment until free from infection. Lord GORELL, and at a later stage Sir MALCOLM MORRIS, presided over the conference, which was attended by a large number of medical officers of clinics and representatives of public health committees from various parts of the country.

The Lord Mayor of London, in welcoming the members, said that the idea of a conference arose out of the experience of the Sanitary Committee of the Corporation that the results of the arrangements for dealing with venereal disease left much to be desired. The expenditure was £3,000 a year, and last year, out of 1,391 people under treatment, 831 left off attending the clinic while still in an infective condition.

For and Against Legislative Measures.

The proposal for fresh legislation was put forward by Dr. C. J. MACALISTER, who thought that some public measures must be taken to impress upon the people the fact that the authorities took a really serious view of the effects which might follow promiscuity. Public opinion was prepared for legislation, and much less importance might now be attached to secrecy than at the commencement of the anti-venereal campaign. Control, both for the sake of the individual concerned and the community, should be exercised throughout the period of treatment. Legislation would necessarily be on the lines of notification. At present there was no obligation for the infected person either to be treated or to remain under treatment. If these diseases were brought out into the open, classified among the other contagious, and dealt with accordingly, they would be brought into proper perspective in relation to morals. Notification itself would be a great means of public education; it need not involve aggressive action any more than in the case of other notifications.

Lady BARNETT pleaded for education rather than compulsion as a means of attaining continuity of treatment. Apparently the anxiety of those hitherto responsible for educative measures to assure the public of the possibility of cure by early treatment had led to a false sense of secrecy. It was not understood that the quick cessation of symptoms in syphilis did not mean cure; that injections of salvarsan could not be relied upon without prolonged treatment by mercury as well; and that when the reaction became negative it did not necessarily mean an absence of sequelae. The serious dangers of gonorrhoea, especially in women; also were not appreciated. Most medical men found less difficulty in ensuring continuity of treatment with private patients than with patients at clinics, probably because the former received a more complete education as to the necessity for continuance, and also because people valued more highly that for which they had to pay. It was impossible to compel people suffering from venereal disease to go to a doctor, for no patient could be expected to diagnose his own case, and presumably no one could be said to have venereal disease until he had been seen by a doctor. Again, any penalty for non-continuance could only follow upon evidence given by a doctor, and this would tend to erode confidence between doctor and patient. If the threat of force influenced some patients to continue treatment, it would deter others from seeking treatment at all. It would also be extremely difficult to prosecute a person said to be suffering from syphilis for not attending until the completion of treatment if in the meantime he showed a negative reaction. She suggested that a more real conception of the nature of the disease should be placed before those attending the clinics; that treatment should be paid for by patients according to their ability; and that the medical profession should consider whether etiquette could not be relaxed so as to allow the doctor after due warning to take measures to prevent the marriage of an infected person.

Mr. CHARLES GIBBS said that the follow-up system had failed. At the London Lock Hospital 908 follow-up letters were written in 1921, but treatment was resumed in only 53 cases in consequence. If a patient received free treatment for a voluntarily contracted disease he incurred some liability to the State which treated him, and this liability could be crystallized into some measure of notification on cessation of treatment. Such notification would involve a report to the medical officer of health, who would be given powers to warn a patient that if he did not continue treatment he would be ordered by a competent legal authority to do so. The clinics as at present constituted were doing such excellent work that they could withstand the taking of such measures.

Dr. J. H. STOWERS said that the principle of notification as applied to zymotic and other infectious diseases had been too long established for its efficacy to be questioned. The time had arrived for a discussion of modified notification of venereal disease. Every possible assistance should be given by the members of the medical profession, but he did not think that they should be the prime movers in the matter.

Liverpool—West Australia—Ontario.

Dr. WILLIAM HANNA said that at the Liverpool clinics in 1921 the number of new cases was 4,800, and of attendances 73,000, but 50 per cent. of the patients gave up treatment before they were free from infection. The annual cost was approximately £16,000. The Liverpool City Council had approved certain proposals to ensure an adequate return on their money, and the proposals had also received the unanimous approval of the Merseyside boroughs.

These suggested regulations provided that every person suffering from any form of venereal disease, as soon as he was aware or had reason to believe that he was so suffering, should consult a medical adviser, and continue to attend his medical adviser until he was deemed free from infection. The doctor should direct the patient's attention to the infectious character of the disease and to the necessity for continuing treatment; he should also arrange for the transfer of the case to another medical adviser when the patient desired. If the patient discontinued treatment without adequate reason the doctor should report to the medical officer of health, who would make inquiries, and, unless satisfied, would cause information to be laid against the patient in a court of summary jurisdiction.

It was also laid down in these regulations that no person should knowingly or wilfully infect any other person, or do or permit any act likely to lead to such infection, the penalties being those provided in Section 1 (3) of the Public Health Act, 1895.

Dr. L. STEWART SANDENAN said that the returns made by officers of clinics already amounted to a form of notification (of cases, not of names), and the notification of ophthalmia neonatorum had been compulsory for some time, and no exception had been taken. If the necessary powers to compel persons to continue treatment were granted to local health authorities it would no more lead to a breach of professional secrecy than the present system, except in the case of those who deliberately refused treatment after repeated warnings, and public opinion would agree that such persons had put themselves outside sympathetic consideration. She referred to the legislation in Western Australia, where notification was made compulsory, without publication of name and address, and any proceedings were heard *in camera*. She favoured a measure which would compel persons who knew or suspected that they were suffering from venereal disease to place themselves under treatment and to continue it until the infectious stage was passed, and would also call upon every medical practitioner to report cases treated by him. It must be a basic principle of any legislation to make it an offence knowingly to infect another person, or do or suffer any act likely to lead to infection of any other person; and legislation must be under public health, not police, administration.

Lieut.-Colonel ARCHIE (late director, Venereal Diseases Section, League of Nations and Cross Societies) gave an account of the system of notification and compulsory treatment adopted by the Provincial Government of Ontario.

This Canadian system provided for notification to the medical officer of health of every case of venereal disease as soon as it came under treatment; the notification was anonymous, serial numbers being used. Every person infected must seek treatment from a practitioner or apply to the medical officer of health, and was bound to continue treatment until pronounced non-infective. Should he fail to do so, he became liable to fine or imprisonment.

The medical officer of health was empowered to require any person who he had been credibly informed was infected with venereal disease, and had infected or was liable to infect other persons, to consult a medical man, and to produce a certificate that he was or was not so suffering. If such a certificate was not

forthcoming the officer was empowered to order an examination of the person so reported, and, if considered necessary, the officer could order his detention and isolation.

The Ontario health officers were confident that their administration of the Act had not led to the concealment of the disease, nor to blackmail, nor to sex discrimination. But the adoption of compulsory measures would make it necessary to establish some standard of non-infectivity, particularly in regard to chronic gonorrhoea in women, and some standard minimum course of treatment and standard of cure in syphilis.

Mr. E. B. TURNER said that one of the objections put forward against notification was that it would drive people to have recourse to quacks or to forgo treatment altogether. But in places where a scheme of notification had been adopted this had not been the experience. From the replies to the questions sent out by the National Council it appeared that the very large majority of the persons consulted were in favour of some form of modified notification and continuous treatment. If compulsion was to be brought about it would be far better to do this by amending legislation than by an order of the Minister of Health.

General Discussion.

About twenty other speakers took part in the general discussion. The majority were in favour of some measure of notification. The feeling in favour of notification appeared to be less marked among the laymen who spoke than among the medical men. Dr. MARGARET RORKE (Blackfriars) said that, in spite of every effort at education and persuasion, a large number of patients at her clinic stopped short of treatment long before they were non-infective, and she believed the time had come for notification of such recalcitrants. Dr. LOUIS PARKES (M.O.H. Chelsea) pointed out that it would not be necessary to have fresh legislation, for the Ministry of Health was already empowered under the Public Health Acts to make the necessary regulations. Dr. DAVID NABARRO suggested that when the health authorities got hold of a syphilitic family by detecting a congenitally syphilitic child they should mark that family and endeavour to induce the mother, should she become pregnant again, to submit herself to treatment. Dr. CHARLES FRANKS (Durham) was inclined to think that legislation would not be beneficial; in any case 95 per cent. of the work must still be done by persuasion. Dr. HAMILTON WOOD (M.O.H. Warwickshire) thought that it would not be just to introduce legislation enforcing continuous treatment on those who had already voluntarily submitted to treatment without at the same time insisting upon all infected persons submitting themselves for treatment. Further, until facilities were complete, power should be given to county councils to adopt compulsory measures only in those areas where proper facilities were available.

Dr. MARY STURGE thought that before a definite decision was arrived at all possible evidence relating to the working of compulsory methods in other countries should be studied. There was still room for educational methods before resorting to compulsion. Dr. LYDIA HENRY (Blackburn) also was of opinion that the resources of education were not exhausted. Dr. WANSEY BAYLY (honorary secretary, Society for the Prevention of Venereal Disease), speaking personally, advocated a scheme which insisted on the immediate notification of primary and secondary syphilis to a special medical officer of health, and the infliction of heavy penalties for omission to notify. Dr. LETITIA FAIRFIELD reminded the conference of the greater responsibility which would be thrown on social workers by the adoption of compulsory methods, for such workers must necessarily play an important part in the machinery necessary for carrying out any system of notification. She suggested that it might be advisable to make syphilis notifiable first, and when that had proved a success to go on to gonorrhoea.

Among the laymen who spoke, the MAYOR OF FELHAM was adverse from compulsory notification, which, he thought, would prevent persons from seeking medical assistance. A representative of the Association for Moral and Social Hygiene was also strongly opposed to legislation; and others spoke in the same sense. On the other hand, the Chairmen of the Paddington and the Battersea Propaganda Committees of the National Council favoured a modified scheme of notification, and the same view was urged by the Chairman of the Scottish Committee. In reply to a Scottish representative, who suggested that the National Council should form a Committee of Inquiry to go publicly into the question and see what measures could be taken to make notification effectual, Sir MALCOLM MORRIS said that this suggestion

would be considered, along with all the other suggestions which had been made at the conference.

No resolutions were submitted (other than votes of thanks), but it was understood that the conference came together for the expression of representative opinions to guide the National Council, and not for the passing of resolutions which might bind it. Certainly the discussion was varied in a five hours' National Council

material for consideration. They ranged from proposals for the better education of the public, especially young women and expectant mothers, to a drastic measure, suggested by Dr. JAMES BUSFIELD, for preventing sexual intercourse with a person suffering from venereal disease.

The Lord Mayor and Dr. James Howarth, the medical officer of health for the City, were warmly thanked for the part they had taken in initiating the conference.

THE HUMAN NEO-CEREBELLUM.

PROFESSOR WINKLER'S LECTURE.

AN exchange lecture arranged by the University of London was delivered at the house of the Royal Society of Medicine on May 3rd by Dr. C. WINKLER, professor of clinical psychiatry in the University of Utrecht, who took for his subject the human neo-cerebellum. Sir FREDERICK MOTT, K.B.E., M.D., F.R.S., who took the chair, welcomed the lecturer as one whose neurological work was known all over the world, and who was director of an institution which could be regarded as a model of its kind.

The lecturer, who spoke in English, first paid a tribute to the British school of neurology and physiology for their work on the functions of the cerebellum, and especially to the memory of Hughlings Jackson, whose clear views on cerebellar functions came as a revelation to his contemporaries.

Professor Winkler introduced the subject of his lecture by an account of a case of olivo-ponto-cerebellar atrophy; the account was illustrated by lantern slides showing the condition found *post mortem*. The patient was a man who was under Professor Winkler's observation for five years, and died at the age of 59; one brother was similarly affected and died of the same disease.

When the patient was first seen the regular symptoms of cerebellar ataxy were present. At the age of 50 the patient had complained of dizziness on moving his head up and down, and at the age of 52 he had the staggering gait of a drunken man. In a very short time his speech became affected. At the age of 53 the patient presented the following characteristic signs and symptoms:

1. *Dysmetria* in all his movements was marked. He could not touch a defined spot with his blackened forefinger. He always pointed with his right forefinger above and to the right, and with the left above and to the left. In later years his movements deviated in other directions.
2. *Dysgymeria*.—On moving his trunk backward she fell with extended legs, never making flexion of the knees. Later all his movements became helpless. When put on his legs he moved the trunk to the left, and trampled desperately with his legs in the air.
3. The upper limbs were very atonic, and there was marked *dysidiadochokinesis* on both sides. It was difficult to estimate the tonus in the lower limbs. The knee and Achilles reflexes were exaggerated. Babinski's sign was never observed.
4. He spoke as if a potato were in his mouth, which made the words unintelligible, and a kind of gibberish.
5. Nystagmus was never observed.
6. He responded well to all tests of touch, pain, and temperature.
7. Vision was bad owing to strong myopia caused by staphyloma posticum without optic atrophy.
8. In the earlier stages hearing was good and the vestibular reflexes were normal. During the last year of his life he became deaf.

He died of pneumonia at the age of 59.

At the autopsy the brain weighed 1,353 grams—a good average weight. There was no affection of the vessels or membranes and nothing abnormal noticeable, except a small pons, a failure of prominence of the olivary bodies, and a smaller cerebellum than normal. Serial sections of the pons and medulla with the cerebellum were made and stained by the usual methods to show the conditions of the cells and fibres. A marked abiotrophy of the pontine, olivary, and arcuate nuclei was demonstrated in Nissl-stained sections; the other nuclei were intact. As a result of this neurone atrophy certain fibre systems were seen to be absent when compared with the normal.

These facts were demonstrated by means of Weigert-stained specimens projected by the lantern. Thus the inner portion of the inferior peduncle, which consists of fibres from the inferior olive and arcuate fibres, was sclerosed, and a very great falling out of fibres from the pons to the middle peduncle was obvious. Consequently, there

was compared with the normal a great loss of fibres in the medullary rays of the cerebellum, but around the dentate nucleus the white matter was well stained, showing that the fibres entering this nucleus were not atrophied. The superior peduncle showed no degeneration. Whereas there was great loss of fibres in the plexus of the granule layer of all the lamellae, the fibres around the Purkinje cells showed a well-marked pericellular fibre plexus. The climbing fibres of the spinal tracts of Gowers and Flechsig have their terminal arborizations in this plexus.

Granted, then, that there was a primary systemic abiotrophy of neurones having a definite destination to the whole of the lateral lobes of the cerebellum, it must, the lecturer said, be asked, What was its functional and biological significance? The nature of the problem became more apparent when these facts were correlated with the results of experimental lesions in animals and embryological investigations on the development of the nervous system in the human subject.

Professor Winkler mentioned the effects of experimental removal of the cerebellum in animals, and showed sections in which the flocculus on one side had not been extirpated. He concluded from a study of Marchi preparations that as long as the layer of granules persisted there was no loss of cells in the nuclei connected with it. The argument he adduced was that the loss of cells in the pontine, olivary, and arcuate nuclei was not consecutive to an atrophied cerebellum in which the layer of granules showed only slight alterations, as was found in the case he described. His view was, therefore, that the cerebellar atrophy which he found was due to an atrophy of the medullary rays the result of a primary atrophy of the pontine, olivary, and arcuate nuclei. The lecturer then referred to the researches of Essick upon the human foetus of 24 cm., in which he showed that two bands of neuroblasts (the bands of Essick) exist—the one, distal, surrounding the bulb laterally, and forming later the olivary and arcuate nuclei; and the other, the proximal band which forms the pontine nuclei.

Professor Winkler expressed the view that these olivo-arcuate-pontine cells, being of later phylogenesis, have not the same vital energy to resist degeneration as is possessed by the evolutionally older cell structures, and are therefore more susceptible to abiotrophy. He considers that these cases of primary olivo-arcuate-pontine degeneration support the embryological observations of Essick, which indicate that these structures are of later evolutionary development. Moreover, the olivo-arcuate fibres in the inferior peduncle are myelinated considerably later than the spino-cerebellar fibres. This was demonstrated by specimens stained by Weigert's method.

Upon these grounds Professor Winkler is of opinion that the views of Edinger and Conolly—based upon studies in comparative anatomy—that the flocculus and vermis constituted the (old) palaco-cerebellum, and the lateral lobes the (new) neo-cerebellum, must be modified. There is not in evolution a superimposition of a new cerebellum upon an old cerebellum, but an interpolation of a new into an old structure. He points out that the preponderant importance of the floccular development is undoubtedly lost in the human subject, but that it still retains a fundamental function connected with static equilibrium. He assumes that the olivo-arcuate-pontine fibres being myelinated at a later date are of later evolutionary origin.

Professor Winkler then illustrated by a wax model the evolution of the neo-cerebellum by interpolation instead of by superimposition of a new on an old cerebellum, but, although it was quite possible, he was unable to assert that there was successive myelination of the cortical cerebellar fields which corresponded to the myelination of the spinal, arcuate, olivary, and pontine fibres.

A vote of thanks to the lecturer was proposed by Dr. HOWARD TOOTH and seconded by Dr. HENRY HEAD, who took the occasion to praise the valuable work which was being done by the exchange of lecturers and to point out that Holland was now the only European country which could be said to be really international in its outlook towards scientific work.

The annual meeting of the French Association for the Advancement of Science will be held from July 24th to 28th at Montpellier.

The Board of Trade is instituting an inquiry into complaints under the Safeguarding of Industries Act that boric acid and metaldehyde have been improperly included in the list of articles chargeable with duty under Part I of the Act, and that gallic acid and "R" tannic acid have been improperly excluded.

British Medical Journal.

SATURDAY, MAY 13TH, 1922.

EXCHANGE LECTURES.

THE University of London is to be congratulated on the initiative it has shown in arranging the series of exchange lectures with professors in the Faculty of Medicine of the University of Paris and in the Medical Faculties of certain Dutch universities. Nothing is more conducive to the development of the scientific spirit than a wide interchange of ideas. Too often difficulties of situation and of language circumscribe the results of some brilliant investigation, and from an educational point of view nothing equals the directly spoken address by one who is a master of his subject.

In the lecture which Professor A. Chauffard of Paris gave at the Royal Society of Medicine on March 23rd, an authorized translation of which is published at page 745, he discussed a problem which he has lately been investigating with the help of P. Brödin and A. Grigaut; the lecture contained a lucid description of the results they have reached as to the nature of the humoral syndrome of gout. Professor Chauffard paid tribute to the classical work of Sydenham, Bright, Gairdner, and Seudamore; he recounted the experiments by which Garrod demonstrated the excess of uric acid in the blood serum of the gouty individual—the crystalline deposit of uric acid upon delicate threads suspended in the serum. While Garrod's method may have lacked scientific accuracy, it is remarkable how closely the quantitative results which he obtained approximate to the more exact colorimetric methods of Folin and Denis. Professor Chauffard estimates that the normal proportion of uric acid per litre of serum varies between four and five centigrams; above this point hyperuricaemia commences. The researches he described confirm the observations first made by Garrod, that in gout there is a definite hyperuricaemia. It is interesting to note that of the 27 cases analysed the only exception to the rule of hyperuricaemia was an instance of juvenile hereditary gout. In this case, while there was an excess of cholesterol and bilirubin in the serum, there was an actual diminution of uric acid. The lecturer suggested that this is to be attributed to an exaggerated permeability of the kidney, and therefore a free elimination of the acid.

In discussing the question of the source of the excess of uric acid Professor Chauffard drew a distinction between endogenous and exogenous varieties: the former he subdivided into two, according to whether the excess of acid was the result of imperfect nitrogenous metabolism and the uric acid derived from the nucleo-protein and purins of the tissues, or whether the excess was the result of a retention by the kidney—he believes that in the early stages of gout there is a holding up of uric acid by the kidney. He described a group of important experiments designed to ascertain the part the liver plays in the metabolism of uric acid. Samples of blood were withdrawn from the portal and hepatic veins of dogs: in some cases the animals were fasting, in others they were fed on a highly nitrogenous diet of sweetbread, liver, or spleen. By estimation of the uric acid content in portal and hepatic blood it was demonstrated that, when a diet containing a considerable proportion of uric acid was given, the coefficient of retention in the liver was as high as 47 to 53 per cent. It was therefore concluded that

during the digestive period a greater or less proportion of the uric acid substance brought by the portal vein is retained by the hepatic cells, the liver playing the part of a regulating organ designed to prevent the passage of the excess of uric acid into the blood. The fate of the uric acid retained in the liver is uncertain, but presumably some at least is utilized in the formation of urea.

Arguing from this experimental basis, Professor Chauffard expressed the belief that the hyperuricaemia of the gouty is an evidence of an insufficiency of the arresting function of the liver, that organ being incapable of retaining uric acid brought from the alimentary canal. The excess of uric acid which thus passes into the system is disposed of in various ways: a certain proportion is eliminated by the kidneys, another part is deposited in joints as sodium urate, in the topoi of the subcutaneous tissues, and in the urate incrustations of the kidney. In addition, there is probably a slight general infiltration of the body tissues with uric acid. Patients with gout are thus suffering from a double hyperuricaemia both in the body cells and in the serum. The syndrome, however, is more complex than a simple hyperuricaemia, and Professor Chauffard and his colleagues have found that there is also an accumulation in the blood of both cholesterol and bilirubin; this they look upon as further evidence of interference with hepatic functions, and the observation may serve to explain the occurrence of gall stones as a concomitant of the gouty state.

An interesting hypothesis was advanced in explanation of the acute crises of gout. Since the researches of Vidal, Abrami, and Lancorese, we have come to look upon these crises as precipitated by a disturbance of the colloidal equilibrium very similar to an anaphylactic reaction. In the gouty individual the uric acid possibly exists in an unstable colloidal form, which at any time may be imperilled by a diversity of disturbing causes—diet, fatigue, cold, etc. If the disturbance is sufficiently intense the acute attack of gout appears, and to the general sensitiveness must be added a local sensitiveness, which causes the inflammatory process to light up always at the same point, creating thus true centres of uric acid crystallization. In fact, the clinical syndrome may be divided into three stages—a latent sensitiveness, a provocative cause, and a local manifestation.

The first of the exchange lectures with the universities in Holland was given by Dr. Winkler, Professor of Clinical Psychiatry in the University of Utrecht, on May 3rd, and a synopsis will be found at page 769. The lecture affords a remarkable example of the application of clinical and pathological observation to a problem of far-reaching scientific importance; though necessarily of a highly technical nature, it was followed with close attention by a large audience. It was a fascinating argument on the structure of the cerebellum from the point of view of comparative anatomy and embryology, and was founded on prolonged observation of a case of primary olivo-arcuate-pontine degeneration. Sections through the cerebellum show a normal amount of the old spino-cerebellar fibres, but all the new fibres, olivo-pontine in origin, entering the cerebellum in the mid-line have disappeared, leaving the intermingled old cerebellar fibres intact; this serves to show that an interpolation, and not a superimposition of new fibres on old, has taken place in the process of evolution. The anatomical findings support the view that the bands of Essick found in the human foetus of 2½ cm. are of later evolutionary origin, and are to be associated with the new cerebellum.

It may be asked what conditions in man can be related with the neo-cerebellum described in the lecture. We are indebted to Sir Frederick Mott, who has had the opportunity of examining Professor

Winkler's preparations at leisure, for the suggestion that it may be correlated with the dissociation of the fore limbs from progression, and the reciprocal simultaneity in the development of the visual directive and the tactile-motor executive faculty of the upper limbs, which has attained an extraordinary development in man. The clinical report shows that the pointing test failed on both sides, and that there was great incoordination and dysidiadokokinesis in both upper limbs. But it may be asked, Why no nystagmus? It may be because there was no evidence of vestibular affection and Deiters's nucleus was not atrophied. Again, bearing in mind the teaching of Hughlings Jackson that one-half of nervous symptoms should be attributed to overaction of unantagonized physiological functionally active structures, it may be assumed that there was no nystagmus because the eyes always act together and not independently; overaction of one neo-cerebellar system as compared with the other did not occur because both systems underwent a simultaneous abiotrophy. Sir Frederiek Mott adds that from a biological point of view it would be of interest to know whether there is a progressive increasing development of these olivo-pontine neural structures in the lemurs (half-apes), apes, and anthropoid apes.

MENTAL HYGIENE.

In the evolution of preventive medicine this country has played a pioneer part, and the names of Simon, Chadwick, Buchanan, Thorne-Thorne, and Power will always be remembered in connexion with sanitary science and the improvement of national health. The scope of preventive medicine has, of course, broadened and undergone the specialization that the progress of science and accumulating administrative experience have rendered necessary. Thus the control of tropical diseases is inseparably associated with the epoch-making work of Manson and Ronald Ross, while of our share in the rise of industrial medicine we can point with satisfaction to the individual efforts of Sir Thomas Oliver on lead poisoning in particular and of dangerous trades in general, to the work done by medical officers attached to the Home Office in the capacity of inspectors of factories, and to the investigations carried on by the Health of Munition Workers Committee during the war, and now the Industrial Fatigue Research Board (Medical Research Council) and its related scientific committees. The subjects of tuberculosis, cancer, alcoholism, and venereal disease have also been specially investigated by associations and other bodies in the hope of devising and enforcing efficient means of prevention. Ordinary medical disease may be compatible with fair efficiency on the part of the sufferer, but even slight mental defect is a most serious handicap to the productive work of the individual; mental hygiene is therefore the necessary supplement to physical hygiene, and the need of steps to prevent and lessen the incidence of mental inefficiency and disease has become glaringly obvious in the light of the experiences of the war. It is an economic problem of grave national importance.

Many years ago the pioneer investigations of the late Sir Francis Galton on heredity laid the foundations of eugenics as a distinct branch of science. It brought together medical, psychiatric, and sociological workers for the study and prevention of mental disorders and deficiency, criminology, and insanity; much valuable work has been done in connexion with mental deficiency, the early detection and education of abnormal children, infant welfare and after-care by various societies and associations, and by individual effort. But the study of mental hygiene has been perhaps less thoroughly organized in this country than in the United States of America, where the capacity of vigorous initiative for combined effort is such a prominent feature and where

as long ago as 1908 a National Committee for Mental Hygiene was established in order to investigate the preventable causes of mental disease, the control of feeble-mindedness, and the problems of criminology. Much has been done by this vigorous committee on these lines, and reference may especially be made to the valuable work of the Phipps clinic at the Johns Hopkins Medical School, Baltimore. In our own country this example has been followed by the establishment last year, under excellent auspices, of the Cassel Hospital at Peushurst for the treatment of 60 patients—drawn from the educated classes but unable to pay the fees of ordinary nursing homes—who are suffering from nervous disturbance not due to organic change or necessitating certification. Four years ago (April, 1918) Canada started a National Council for Mental Hygiene, which enforced the principles of the earliest possible detection of mental defects, of special educational facilities in the regular schools for meeting the needs of defective children, and of the establishment of mental clinics. The French Ligue d'Hygiène mentale, founded in December, 1920, has ten committees studying various aspects of the subject—such as the relation of mental disorders to general diseases and intoxication, the struggle against alcoholism, the treatment of abnormal children, psychology of trades, the out-patient treatment of early mental disturbance, reforms in the care of the insane, the organization of psychiatric teaching, and propaganda in mental hygiene. A congress arranged by this body is to be held on June 1st to 4th next; at it the following subjects are down for discussion: the treatment of psychopaths, occupational selection in relation to mental hygiene, educational methods and applied psychology, and mental hygiene in the family. National Councils for mental hygiene not only link up the various bodies working in their own countries but, by combining with similar councils, form an international bureau for the communication of knowledge thus collected for wider distribution and for propaganda.

The proceedings of a provisional committee which held a meeting at the rooms of the Royal Society of Medicine, under the chairmanship of Sir Courtauld Thomson, on May 4th are reported elsewhere in this issue. The object was to establish a National Council for Mental Hygiene on the same lines as the National Councils mentioned above. Since its aims are wide and will extend far beyond those ordinarily regarded as the aims of pure medicine, this Council will, it is to be hoped, receive the support of many whose activities lie in other directions. It will, in the first place, encourage, correlate, and organize means of communication between the existing associations and institutions in this country interested in mental health and disease; it will join with the Councils of other nations in an international league for the spread and utilization of knowledge thus accumulated; it will study the etiology and further the prevention of functional nervous and mental disorders by investigating the problems of heredity, environment, alcohol, syphilis, and industrial and other conditions; it will endeavour to obtain for the somewhat neglected subject of mental hygiene a more prominent place in medical education, so that the newly qualified practitioner, one half of whose patients have some form of minor mental manifestation, will no longer find himself so much handicapped in his equipment; it will further the establishment at general hospitals of psychological clinics, such as Dr. H. Rayner originated many years ago at St. Thomas's Hospital, for the treatment of the early stages of mental disorders; it will investigate the means of organizing the conditions for treatment, especially of the early stages, of mental disorder, of attracting a good class of educated persons as attendants, and of arranging for

workers trained in social service to visit the patients of the psychological clinics in their homes. By judicious propaganda it will seek to spread among the general public sound knowledge of the principles underlying mental health and disease. Parents must be enlightened in the right way of bringing up their children, and schoolmasters and other teachers must be instructed in the importance of the influence that they can exert on the mental health of their pupils. Long as is this list, it does not exhaust the potential activities of the National Council; criminology and penology urgently require consideration, and, as Dr. Henry Head pointed out in his address, recent research shows the importance of mental hygiene in the life and productive power of the industrial worker.

SECOND THOUGHTS ON THE BUDGET.

THERE was a general feeling of relief when it was known that the reduction in the income tax which the daily press had foreshadowed was contained in the Government's proposals for 1922-23. That feeling was due in part to a sort of tacit assumption that the fiscal problem could not be so dangerous as had been suggested if the Chancellor could speak, with all the information obtained through official channels, of hopeful signs of trade revival and then proceed to reduce the load of taxation. A more prolonged consideration of the facts leads to a clearer recognition of the unpleasantness of having to admit that the nation must renounce for the present its programme for paying off debt, and of the lack of any solid ground for supposing that that programme can be resumed next year unless, in the meantime, there can be put into force those further and more drastic economies which are so earnestly desired by everybody and so difficult of achievement by anyone.

A factor which is sometimes lost sight of, but the importance of which it is not easy to exaggerate, lies in the system of "graduation," which applies not only to income tax and super-tax, but also to the death duties. In a period of currency inflation, such as that during which the various war issues were floated, prices and profits are at a high monetary level and the yield of the income tax is more than proportionately high. What we are now experiencing is the converse—a fall in monetary values and a more than proportionately reduced yield of income tax. This is a general tendency, of which the present trade depression is a necessary accompaniment and aggravation. Unfortunately, to whatever level monetary values and the general rate of interest fall, on the long-dated Government loans the "war" rate of interest will have to be paid—assuming as we do that the schemes for compulsory reduction advocated in some quarters meet with the fate that such confiscatory schemes deserve. The golden time for repayment of debt was when values stood high and the income tax yielded its maximum return to the Exchequer; but for the present the country has shot its bolt, and most students of industrial problems are agreed that some relief from taxation is almost essential if the hope of renewed trade activity is to be realized. Whether that renewal can be accomplished, and, if so, whether it will produce a sufficiently increased revenue to enable repayment of loan to be resumed, are the questions which lie at the root of the whole problem, and their solution by the facts of this financial year will go far towards determining the fiscal history of the next decade. In the meantime the expenditure side of the national accounts has one or two hopeful features. It is an open secret that the departmental estimates were based on a Board of Trade index figure of 100 per cent. above pre-war levels, and the subsequent fall in prices should result in savings

accruing to the Treasury; moreover, in spite of the comparative small margin of £25,000,000 allowed for Supplementary Estimates, an energetic pursuance of a policy of economy throughout the year may yet succeed in showing a balance on the right side of the account at the end of the year. The Budget has been attacked as an income-tax-payers' budget; it is an unfair description, but it has this much of truth in it, that the financial burden of the war was very largely borne by that section of the community, and it is only right that they should be among the first to feel relief. Its extent may be gathered from the table printed at page 777; it will at least be apparent that the burden remaining is sufficiently heavy to entail a real sacrifice on the part of every taxpayer.

It is proposed that several minor alterations in the Income Tax Acts should be made; the only one likely to concern any considerable number of our readers is that for placing all employed persons under Schedule E, in which case tax will be payable on the income of the current year instead of on the three years' average. For this procedure the Chancellor was able to claim the support of the Royal Commission on the Income Tax, though apparently the change will at first involve the Revenue in some loss, seeing that the three years' average for 1922-23 still contains one "good" year—namely, 1919. The success or failure of this change will depend largely on the manner in which it is carried out; if, for instance, employed persons are to be worried for small supplementary payments because their emoluments have risen to some small extent during the year, we think that they will succeed in convincing the authorities that the old definite basis provided by the previous years had much to recommend it. It would be useful if it could be made clear, in Committee or otherwise, that persons whose main income falls for assessment under Schedule D could include therein the income from employments, provided that the services given are of an ordinary professional character; that would regularize, so far as the medical profession is concerned, an existing practice which might otherwise be in jeopardy.

Little comment on the other changes to be effected by the Budget is called for here. The reduction in the postal rates is, perhaps, the most welcome, even though it is accompanied by narrower limits as to weight and unaccompanied by any reduction in the stamp duties levied on receipts or cheques. The country may have more misgivings than the Chancellor shows in his laudatory observations on the past achievements of the British taxpayer, but has none the less good reason to feel thankful that the past financial year has closed without disaster and that the present one begins with some prospect of relief from the almost intolerable burdens of the past few years.

MOTOR TAXATION.

MR. H. MASSAC BUIST writes to express the view that the relief of 1s. in the £ on income tax is more valuable to motorists, particularly to professional men, than any concession in the matter of car licence fees. He points out that no recommendation by the Departmental Committee on Motor Vehicle Taxation, which is now investigating the matter, could be brought into effect for twelve months. In my notes on this subject in the JOURNAL of April 29th (he says) I attempted to compress the history of motor vehicle taxation overmuch, with the result that I wrote that the original horse-power tax was introduced in 1904, whereas it was incorporated in the Budget of 1909, at the same time as a duty of threepence a gallon, subject to certain rebates, was imposed on petrol. This scheme replaced a tax according to vehicle weight, a system which no organization concerned with passenger-cars

advocates to-day. A reduction in the price of petrol may be announced even before these issues appear in print, and that despite the fact that the oil market in America, which controls prices throughout the world, is looking, not for a fall, but for a rise in the price of fuel. Any fall in direct taxation in this country assists the lowering of the cost of fuel, because all these charges are passed on automatically by the fuel-vending organizations, which are established for the purpose of making profit by their enterprise and not to collect revenue for any Government. Therefore the relief to the motorist by the process of reducing income tax results in a still further benefit by assisting to bring about a lowering of fuel costs, which are a more important part of the expense involved by the ownership of a motor vehicle than the cost of a licence fee. Furthermore, as long as the insurance rates on motor vehicles rule on the scale we have experienced in the post-war period, so long will it be practically impossible to make any reasonable case against present taxes as too high. Further, if it could be proved that the sales of the cheapest form of American car, even if assembled or part manufactured in this country, were affected adversely by the present taxes so that fewer of these machines than of other makes were coming into use, there might be some solid ground for recasting the basis of the levy. But the plain fact is that the car which continues to sell in greatest numbers is the Ford. Any other manufacturer, British or foreign, would be glad to sell as many motor cars in this country, or cars to the same value in terms of pounds, as the Ford turnover. While that obtains there is no argument that would induce a Chancellor of the Exchequer to recast the whole system of motor taxation. The campaign that aims at getting the horse-power tax removed, and the levy placed on fuel, is based always on seeing the individual motorist's support by pointing out to him that he will be paying less taxes. Yet the organizers of that campaign admit that the net amount of revenue to be raised by such taxation must be the same. One section implies that the solution of the problem lies in causing the commercial motorist to carry part of the burden at present borne by the private passenger-car owner. It is, however, so essential to assist commerce and industry in all their aspects that no such scheme can ever meet with the approval of Government, no matter of what cast of politics. Therefore, another section contents itself with pointing out to each car-owner in turn that he is paying too much tax and that some other passenger-car owner will pay more by the given new scheme. Those who advocate a change in the basis of taxation do not seem to seek out the private car-owner who, under a new scheme, would be paying not less but more in motor taxes than he is doing under the present system. Yet the man it is proposed to charge more has a right to be consulted. For instance, it is obvious that the mileage of medical men would bring them into the category of those who would pay more than the ordinary motorist who keeps a car for odd work or week-end pleasure runs. When the fuel tax was in force this fact was recognized by giving medical men rebates of 50 per cent. off the duty. The objections to reintroducing any scheme of taxation on fuel involving rebates are that the system led to leakages and that the cost of collection was more than the yield was worth. Most motoring bodies agree that any scheme for a return to a fuel tax must be based on the principle of no rebate for any class of user. Yet any scheme for the taxation of fuel must bear hardly on those who use cars for business or professional purposes; among them would be medical men, who would, in the long run, pay more in order that those motorists who do not use their cars so habitually might pay less. The more I ponder the matter (Mr. Buist continues) the more I come back to the point that we had better leave our motor taxes as they are and organize ourselves instead, to insist that the moneys we contribute are applied effectively to the purpose for which they are levied—namely, the provision of better and still better roads; for such provision, incidentally, would save us much in petrol and in tyre costs per annum. As it is, our money is being wasted overmuch. That process will continue

so long as we remain disorganized among ourselves, quarrelling because each individual is made to believe that he is paying a few shillings, or perhaps pounds, a year more than otherwise he would.

REGULATIONS TO PREVENT LEAD POISONING.

A PAMPHLET on the regulations regarding the manufacture and use of lead and its compounds in various countries has been issued by the Stationery Office. Its appearance is in one sense opportune, for it was only in October last that at the Labour Conference of the League of Nations in Geneva the question of the employment of lead in painting was raised; it was insufficiently discussed and rather hurriedly voted upon. The object of the pamphlet, prepared for the Governors of the Imperial Mineral Resources Bureau, is to show how, by regulations, work in lead has become less dangerous than it was half a century ago. The author, Mr. Stone, has given more than a mere summary of industrial legislation in various countries. The lead-producing countries of the world are the United States, Germany, Austria, and Mexico. Lead ores are mostly sulphide (galena) and carbonate (cerussite). Experience all the world over, with the one exception of Broken Hill, has shown that the mining of galena is not followed by lead poisoning. The dust given off in the mines has, however, been a frequent cause of pneumoconiosis. This was the case three or four decades ago in lead miners working in the remote dales of the county of Durham. As regards regulations for lead works there are none in any country superior to those of Great Britain. Several of the other countries have taken their cue from her. In New South Wales, under the Mines Inspection Act, 1901, in the regulations regarding red lead and flue dust, it is required that the dust must be carefully wetted as soon as it is drawn from the flue, also that the furnaces in which lead is undergoing conversion shall be hooded. Baths, provided with hot and cold water, and "changing bonnets" are arranged for. In Canada, where 1,058 men are employed in lead smelting and 5,795 in industries making use of lead, it has not been found necessary to introduce many special regulations. In the United States regulations provide for the elimination of dust by water sprinkling, the use of automatic machine sampling and of exhaust ventilation. Where dust cannot be prevented respirators must be worn, and in dangerous processes overalls also; shower baths must be provided and convenient lunch rooms. The regulations regarding red lead works in France are of quite a high order. A medical examination of all applicants for work is compulsory, and a medical certificate must be produced stating that the applicant shows no signs of plumbism or of any illness likely to be aggravated by working in lead. The certificate must be renewed one month after the engagement, and afterwards once a quarter. A register of illnesses is also kept. In Germany attention is particularly directed to the prevention of dust. Floors must be wet cleaned daily. No dust-collecting chamber or flue must be entered by workmen until it has been cooled and ventilated. Impermeable gloves must be worn or the hands well greased, when they are liable to come into contact with lead salts in solution. Food is not allowed to be taken into the workrooms, and smoking is prohibited. A monthly examination of the workers is required. Women and young persons are not allowed into flue dust chambers. The regulations in Austria regarding the escape of dust and fumes are said by Mr. Stone to be far better than those of any other country. They certainly ran Great Britain rather hard. We shall not be far wrong in saying that Professor Telcky has largely contributed to that state of things. Specimens of air in certain parts of the works are taken under a special order of the mining authority and analysed by competent chemists to ascertain the amount of lead it contains, and a record is kept of these analyses. Cleanliness is rigidly insisted upon and ample bathing facilities provided. Medical examination

Laws and Regulations relating to Lead Poisoning; being an Analysis with Texts of the Laws and Regulations made in the Chief Industrial Countries to Prevent Plumbism. By Gilbert Stone, Barrister-at-Law, B.A., LL.B. Kingsway, London: His Majesty's Stationery Office. 1922. (Med. 8vo, pp. 250. 5s. net.)

of the workers is imperative. Regulations for white lead works are but an extension of those used in other departments of the lead industry; those in force in Great Britain have been attended by the most satisfactory results from a health point of view. The number of cases of plumbism in the white lead industries has been progressively reduced. In 1900-1904 there were 183 cases; in 1905-1909, 76; in 1910-1914, 31; in 1915-1919, 17. In Great Britain no person can work in a white lead factory for more than a week without a medical certificate. The regulations in France and Germany are on lines similar to those in Great Britain. The regulations in Belgium deal effectively with dust. It was in 1906 that the Workmen's Compensation Act came into operation in Great Britain. Lead poisoning was then scheduled as an industrial disease. One of the immediate results of this was a rise in the number of cases of lead poisoning reported in the manufacture of pottery. It is interesting to note that while in 1906 in this country lead poisoning was made an industrial disease and qualified the sufferer for compensation, in the United States it is not regarded as an industrial disease but as an "injury," the meaning of which word in some of the States is "an injury or disease arising out of employment." The tendency, however, nearly all the world over is to regard lead poisoning as a disease arising out of, or in the course of, occupation, and to be compensated. One of the effects of bringing lead poisoning under the Workmen's Compensation Act has been not only to increase the notification of the minor forms of the malady, but to bring within the meaning of the Act such consequences of working in lead as nephritis and cerebral haemorrhage. Mr. Stono has given to all who are interested in the subject of lead poisoning an extremely useful compilation. It ought to be of use to medical officers of lead works and to certifying factory surgeons.

THE CASSEL HOSPITAL FOR FUNCTIONAL NERVOUS DISEASE.

In connexion with the establishment of a National Council for Mental Hygiene at the preliminary meeting held on May 4th, the unobtrusive activities of the Cassel Hospital for Functional Nervous Disease, founded and endowed last year by the late Sir Ernest Cassel, naturally occur to mind. Its object, as pointed out in our columns a year ago (1921, i, 680), is to provide for members of the educated classes who cannot afford the expense of professional care in nursing homes, and are not certifiable, the most efficient treatment for the conditions commonly known as neurasthenia, nervous breakdown, and loss of power not associated with definite structural change. The provisions made for the care of such patients at the Cassel Hospital, Swaylands, close to Penshurst, are ideal; the hospital is a fine mansion in quiet and beautiful surroundings with extensive grounds containing a wonderful rock garden, tennis courts, and a golf course. The medical director (Dr. T. A. Ross) and two other medical officers have charge of the sixty patients, whose treatment consists in sympathetic consultations conducted with tact and without any suspicion of hurry. By the appointment of Major H. Hume to manage the business side of the hospital Dr. T. A. Ross has been wisely relieved of responsibilities and distractions which so often prevent medical superintendents from devoting a whole-minded attention to the purely professional supervision of the patients. There is in addition a strong medical committee, the members of which, when occasion arises, willingly provide individual assistance in the exceptional cases requiring special consultation.

THE SCHICK REACTION.

In the *St. Bartholomew's Hospital Journal* for May, 1922, Sir Frederick Andrewes, F.R.S., publishes an interesting note on the reactions of 157 students to the Schick test for identifying individuals susceptible to diphtheria.¹ It had been inferred from the results of various workers that the proportion of immune persons in any population was a

function of the economic status of the population tested—that it would generally be higher in the lower than in the middle or upper classes. Zingher, for instance, found over 80 per cent. immune in the school population of poor districts of New York, but only 33 per cent. in good-class schools. Sir Frederick's results are consistent with the truth of the hypothesis. Of the 157 students tested, 103, or 65.6 per cent., gave a positive result—that is to say, only 34.4 per cent. were immune. Blood was taken from a good number of the volunteers and tested on guinea-pigs. The immunes had from 0.1 to 5 units of antitoxin per cubic centimetre; among the non-immunes 27 out of 30 cases had none, or less than 0.001 unit; the remaining 3 appeared to have small amounts and are being reinvestigated. Of 21 men who said they had had diphtheria, 15 were positive and 6 negative, illustrating the well-known fact that an attack of clinical diphtheria may confer but little protection. Pseudo-reactions were fairly common. The tests themselves were carried out by Dr. O'Brien and his colleagues.

THE WEIGHTS OF INFANTS.

We print elsewhere a letter from Professor Karl Pearson on the information to be derived from the record of weights of infants. Professor Pearson, on the basis of numerous statistical data accumulated in the Francis Galton Laboratory, has constructed two charts which should supersede those in actual use.¹ Not only can one read off from the chart the relation between an infant's actual weight and that of the general average in working-class families, but one can also make a rough prediction of the infant's fate at the end of the first year of life. This latter possibility has been attained by statistical study of the after-histories of babies of different weights. For instance, suppose a certain female infant aged 16 weeks weighed 14 lb. The chart tells us that less than 15 per cent. of all female babies of that age are heavier. If now, merely using the datum of weight, we ask what are the infant's prospects at the end of fifty-two weeks from birth, the chart informs us that not many more than 35 per cent. of all babies will be found healthier than this one. Of course such a prediction is not very secure. As Professor Pearson points out, weight is by no means the only factor in the health of the baby; the statistical correlation of an index of health and weight is less than 0.5. But the charts will be exceedingly useful for interpreting the significance of plotted weights. It will be easy to learn whether a child is maintaining or improving its grade of weight and health. Those in charge of infant welfare centres and clinics will, we feel sure, welcome this method of investigation.

FAMINE AND DISEASE IN EAST EUROPE.

The three last reports of the Provisional Health Organization of the League of Nations, issued on March 25th, April 4th, and April 13th, contain general information on the epidemic situation in the famine zone of the Ukraine; an enumeration of the cases of cholera in the Ukraine and in Russia; and statistics of infectious diseases in Poland, Latvia, and Hungary. In the Southern Ukraine the districts of Odessa and Nikolaiev are the most seriously affected, and 25 per cent. of adult mortality and 40 to 50 per cent. of infant mortality is attributed directly or indirectly to famine. Medical reports indicate a lessening physiological resistance in the population due to the famine and the use of food substitutes. Another circumstance which becomes more serious with the approach of summer is the bad condition of the water supply. In Odessa the waterworks are no longer in use; the reservoirs, which are 42 km. from the town, in the middle of the famine zone, have been abandoned by the workers. Water is sold in the streets at 25,000 roubles a jar; hospitals obtain water with great difficulty; the inhabitants have been using snow and rain water, but this source of supply will very soon fail. Cholera reports for April show a more serious spread of the disease than that indicated

¹ The pair of charts separately mounted can be purchased from the Cambridge University Press, Fetter Lane, E.C.4, for 7s. 6d. net.

¹ BRITISH MEDICAL JOURNAL, 1921, vol. ii, pp. 991, 1001 (December 10th).

by the figures for March. From January 1st to March 31st 1,165 cases were reported from the Ukraine. The epidemic originated in the migrations of refugees from famine zones and it spread along the railway lines, as is indicated by the numerous cases of cholera among railwaymen and in the towns situated on important railway lines. Strict sanitary control at railway junctions is urgently necessary. In Russia proper 299 cases of cholera were reported between January 1st and February 18th, occurring in widely different localities. The reappearance of this disease over a wide area from the beginning of the year is a disquieting feature of the reports. The epidemic condition of the countries bordering on Russia remains serious. From February 4th to 19th, according to provisional information, there were in Poland 5,140 cases of relapsing fever with 203 deaths; other figures are as follows: Typhus 3,730, and 275 deaths; enteric fever 1,036, and 68 deaths; dysentery 136, and 10 deaths; small-pox 106, and 24 deaths. The progress of relapsing fever in Poland has been as follows: In 1919, 2,376 cases with 153 deaths; in 1920, 7,079 and 293; in 1921, 14,163 and 414; for the first seven weeks of 1922, 13,415 cases and 592 deaths.

THE OUTLOOK IN TROPICAL MEDICINE.

DR. ANDREW BALFOUR, at the Royal Sanitary Institute, on April 26th, delivered an address on the outlook in tropical medicine. His keynote was the value of research coupled with the importance of education of both the general public at home and the indigenous tropical races in sanitary hygiene and the prevention of disease. Advance in knowledge of the cause and process of disease alike in temperate and tropical climates had long suffered from the bane of empiricism. Conservatism and hide-bound beliefs were hard to die. The fetish of fumigation and disinfection for the elimination of disease was often but a cloak for ignorance of the true causes of infection, which enlightened research had done, but still needed to do, much to remove. Granted a man possessed the qualities which fitted him for research, it was of the utmost importance that his work should not be hampered by the calls of routine examination coming from hospital or private sources. He should be left absolutely free and unhindered to carry out his own line of research in his own way. Yet it was remarkable what had been accomplished in the course of routine work. The late Sir Patrick Manson, when engaged in general practice at Amoy, made his first discoveries in filariasis. Constant revision of accepted beliefs as to the cause and course of infective processes, particularly in tropical disease, was needed to verify the correctness of our conclusions. Dr. Balfour instanced ankylosomiasis and plague. With regard to the former, he said that recent observation by American workers had shown the pig to be a disseminator of hookworm larvae, a fact hitherto not generally recognized, although previously suggested by investigators in South Australia. For the prevention of plague it was doubtful whether efforts to destroy the rat were being pursued on right lines. The fact that their fertility and rate of breeding surpassed the rate at which they could be exterminated suggested that measures should be directed to checking their productivity. Attempts based on a study of the bacteriology of the pro-genital tract of the animal had been made with a view to causing infective abortion and sterility, but so far without success. Sanitation in the tropics was a subject which until the war had received but little serious attention. Thanks, however, to the lessons learnt in the past eight years courses of instruction were now open to men and women to qualify as sanitary inspectors in the colonies, and a diploma in sanitary science as applied to the tropics was now available.

BIOLOGICAL STUDIES IN THE MADEIRAS.

DR. MICHAEL GRABHAM, who lectured at the Royal Institution on May 5th on biological studies in the Madeiras, had a fascinating story to tell of the life that is to be found on and about those mountain tops in the Atlantic. Each island of

the archipelago appears to have a distinct geological history, and this is borne out by biological evidence—for example, each island or rock has its own peculiar examples of the *Testacea*, and only six or seven of the 170 species are common to all the islands in the group. The Atlantic might be lowered a hundred fathoms without merging the great component rocks of the Madeiras in a common connexion. At the time when Madeira came into human occupation five hundred years ago—for Dr. Grabham rejected the fables of an earlier settlement—the flora and fauna were already specialized and established. Just as the surface of chalk at Eastbourne has undergone no appreciable change since Caesar's camp was pitched upon it, so, to judge from the fossils, the biological conditions in Madeira existed as they do now for long ages before the advent of man. It would be less bewildering to believe, said Dr. Grabham, that all the specialized forms of life to be found in these Atlantic islands were human introductions than to trace their descent in the dim past from ancestral forms which no longer survived. He described some of the plants in detail, especially the *Sechium edule*, which yielded a fruit not unlike a pear, possessing highly nutritious properties, which were appreciated during the war when the U-boats were threatening food supplies. Madeira, however, has suffered greatly from plant pests, for which its winterless climate is supposed to be congenial. He spoke especially of the recent depredations of the Argentine ant (*Iridomyrmex humilis*), and said that if it was true that the British Isles were already invaded by this insect it would be advisable for the Ministry of Agriculture to study American experience in countering its ravages and their own experience in Madeira. This ant established itself in Madeira in destructive colonies up to 2,500 feet above sea-level. Coffee cultivation was ruined, and every sort of fruit tree—the citrus especially—which would support coccus or aphid was attacked. By surrounding a lemon tree with a circle of powdered potassium cyanide, so that every ant in passing to or from the tree was killed, he found that more than forty thousand ants had been engaged in draining one tree of its vitality. There was no foundation, however, for the statement that the birds of Madeira had been destroyed by the Argentine ant, for Madeira was as full of bird music as ever. The ant had many enemies, especially spiders, which spread loosely stretched snares in every corner; and there were signs now that the first wild activity of this pest was abating. The turbulent seas around Madeira were extremely interesting from the biological point of view. One engaging fish which he exhibited was a species of bass, essentially sub-tropical, but occasionally found in the English Channel, where it was known as the wreckfish. In Madeira its beautiful white flesh was appreciated. Generally it lived well away in the open sea at a depth of from 2,000 to 3,000 feet, and when it was caught and drawn up to the surface from this astonishing depth it came up so distended as to be, not indeed dead, but in a cataleptic condition. In this fish the air bladder was prolonged into a tube which penetrated the brain, and with its attachment by ossicles seemed to serve as a resonator and interpreter of weak vibrations. He had examined the stomachs of fishes drawn up from very great depths, and had generally found them empty; but the fishes were in good condition, as though in these depths they relied upon the absorption of much of their nourishment from the substantial supply which it was believed was held in solution in sea water. Occasionally great commotions occurred in the submarine depths about Madeira. In one instance, while some cable work was taking place, an agitation occurred which lasted with increasing intensity for four days and then suddenly stopped. Many miles of submarine cable disappeared, and the ocean floor had to be explored for fifteen miles before an undisturbed bed was found. Nothing of this catastrophe would have been known but for the cable experiments which were proceeding at the time. In these deep-sea catastrophes there was widespread destruction of marine life, as though the water had been poisoned by the release of noxious volcanic vapours.

IMPORTANCE OF EARLY TREATMENT OF CANCER.

LEICESTER, following the example set some years ago by Portsmouth, has taken steps to call the attention of the public to the danger of failing to recognize the early signs of cancer or of failing to seek medical advice so soon as any suspicion arises. A public notice, signed by the medical officer of health, Dr. C. K. Millard, has been inserted in the newspapers, and a leaflet has been prepared for distribution from the Health Department and by health visitors. The public notice points out that in the early or localized stage it is often quite possible for cancer to be completely removed by a surgical operation, but that very many cases are found to have got beyond the curable stage when the sufferers first apply for treatment. "In this disease immediate action is imperative, and delay is disastrous. Everything depends, therefore, upon early resort to skilled medical advice, recognition of the disease, an early operation, and prompt treatment." It is added that treatment by radium or x-rays, though hopeful, is still in the experimental stage, and the very necessary statement is made that "although many alleged 'cures' have been announced, there are none which have so far substantiated the claims made for them." The leaflet points out that of the number of persons who die each year from cancer—and that number is increasing—many could have been cured if they had applied earlier for medical advice, and that cancer in its early and curable stage may give rise to no pain or feeling of ill health. Special attention is directed to the early symptoms of cancer of the breast and of the uterus, to the danger of warts on the lower lip, or any sore or swelling on the tongue in men over 45, and to the early symptoms of rectal cancer. In each instance it is emphatically pointed out that a large proportion of such cases are curable, and in their early stage are curable. On the first page of this leaflet, which is based on that issued at Portsmouth, it is said: "The importance of this subject to the public is shown by the fact that of all deaths of persons over 40 years of age, one in nine is from cancer."

INDUSTRIAL HYGIENE.

ACCORDING to *Industrial and Labour Information*, issued by the International Labour Office of the League of Nations, a Workers' Health Bureau has been founded in the United States by the trade unions as a co-operative undertaking. A pamphlet, which has been published to explain the aims of the bureau, emphasizes the importance of preventive work and health education. It is suggested that each union should organize its own health work and carry it on with the advice and co-operation of the Workers' Health Bureau. The advisory committee of the bureau includes a medical expert, whose advice will be at the disposal of the trade unions in the setting up of their own health departments. The objects of the bureau are: To conduct a scientific industrial study of the health needs of any trade union and recommend a health programme for that trade union based on such study; to recommend an educational programme covering the subject of workers' health; to establish health departments within local trade union branches; to train workers' health committees to carry out the health programme in the workshops; and to select doctors, nurses, and teachers for conducting the union's health work. The Industrial Hygiene Section of the International Labour Office, Geneva, proposes to publish from time to time a series of notes giving information regarding new publications on industrial hygiene. The notes will be universal in scope, and in order that they may be as complete as possible it is desired to include references, not only to books, but also to occasional articles and reprints of lectures published in medical or other periodicals. The International Labour Office therefore asks members of the medical profession and others interested in problems of industrial health to send particulars of any new publications, including articles in periodicals, suitable for inclusion in the lists. Such information should be addressed to the Industrial Hygiene Section, International Labour Office, Geneva, Switzerland; it should comprise the author's

name, the title of the book or article, and the publisher's name, or, in the case of an article, the name, date, and number of the periodical in which it appears. In return the International Labour Office will be glad to supply its correspondents with the bibliographical notes as they are issued.

THE ANGLO-BATAVIAN SOCIETY.

THE Anglo-Batavian Society was founded in May, 1920, with the object of promoting good fellowship between the British and Dutch peoples. Among the admirable activities of the society it has taken a share in arranging an exchange of medical and scientific lectures between Holland and England. The scheme was successfully initiated last year, and the first of the series given in England this year was that on the human neo-cerebellum delivered by Professor Winkler, of Utrecht, on May 3rd, as more fully related at page 769. On the evening of the same day the Anglo-Batavian Society gave a dinner in honour of Professor Winkler at the Langham Hotel. Sir Walter Townley, K.C.M.G., formerly British Minister to the Netherlands, was in the chair, and among the guests present were Professor Geyl, Sir D'Arcy and Lady Power, Sir Frederick and Lady Mott, Sir James and Lady Purves Stewart, Sir John MacAlister, Professor and Mrs. Bayliss, and Professor and Mrs. Starling. After the loyal toasts had been honoured, Sir Walter Townley proposed the health of Professor Winkler, who responded in excellent English, expressing his thanks for the reception he had received in London and his hopes for the continuance of cordial relations between the two countries. The toast of "The Anglo-Batavian Society" was proposed by Professor Starling, and, in the unavoidable absence of the Netherlands Minister (Mr. Crommelin), Dr. Bisschop, honorary secretary of the society, responded. The society, he said, included in its scope the encouragement of Anglo-Dutch football matches and regattas, as well as the promotion of scientific lectures. The toast of "The Other Guests" was proposed by Sir D'Arcy Power, and responded to by Sir James Purves Stewart, and the health of the Chairman was given by Dr. Roosmalen Neuren, of the Dutch Legation.

At the annual meeting of the Medical Society of London Lord Dawson of Penn was elected President for what will be the 150th year of the Society's existence.

THE Cavendish Lecture of the West London Medical-Chirurgical Society will be delivered on June 13th, at 8.15 p.m., at the Kensington Town Hall, by Professor Harvey Cushing, M.D., on "The meningiomas (dural endotheliomas), their source and favoured seats of origin." The lecture will be followed by the annual conversazione of the society.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Venereal Disease: Disinfection Policy.

SIR J. D. REES asked, on May 4th, how many county councils, county boroughs, and borough councils have adopted the immediate self-disinfection policy of the Society for the Prevention of Venereal Disease. Sir A. Mond said that as grants were not payable in respect of measures in pursuance of the policy mentioned he had no special information as to the extent to which that policy had been adopted, but so far as he was aware it had never even been claimed that more than an extremely small proportion of the local authorities concerned had adopted it.

Grants to Voluntary Hospitals.—Mr. Charles Edwards asked, on May 3rd, whether the Minister of Health had received a protest from the Royal Gwent Hospital, Newport (Mon.), and similar institutions, against the decision of the Voluntary Hospitals Commission that the grants for hospitals should be based on the income for the year ended December 31st, 1920, or the three years 1918, 1919, 1920; whether the Minister was aware that for the year 1921, and the immediate following years, it would be impossible to show a similar income owing to reduced earnings of workers and others; and whether, in order that the hospitals should derive some benefit from the half million sterling set aside by the Government, he would amend the terms and conditions. Sir A. Mond replied that representations in this sense had been made to the Voluntary Hospitals Commission by certain hospitals in South Wales. It was the Government's policy, as one of the

fundamental conditions for grant, that assistance should ordinarily be based on the amount of new money raised or in sight; the Commission had no power to vary this rule, but might make emergency grants in cases where a hospital had exhausted its realizable assets, and without assistance would be compelled to close beds.

Illegal Traffic in Drugs.—Mr. Ramsden, on May 4th, raised the question again whether the powers of punishment for illegal trafficking in drugs were adequate. Mr. Shortt recalled that the regulations only came into force on September 1st last. They were being carefully watched by the Home Office, which was in close touch with the police authorities, and if it appeared that the present powers were insufficient he should not hesitate to come to Parliament for more. It was clear, however, in view of the international character of the traffic, that it could be effectively dealt with only by international co-operation, and the whole question of the measures necessary to cope with this traffic has been engaging the attention of the Advisory Committee appointed by the League of Nations.

Flagging for Drug Traffickers.—On inquiry by Colonel Burn whether the Government would support legislation to authorize flogging and imprisonment without the option of a fine for individuals convicted of carrying on the illicit drug traffic in this country, and deportation in addition, if the offender was an alien, Mr. Shortt said, on May 9th, that the question of taking further powers and extending the law was under consideration. The power to deport already existed, and was used whenever possible.

Women Medical Students.—Mr. T. Griffiths asked, on May 4th, whether in view of the fact that a Government grant of £30,000 a year had been made to five London hospitals where clinical units had been set up, that a Government grant of £16,000 had been promised this year to the London Hospital, in which was included £3,000 from the University Grants Committee, and that the last named hospital now excluded women medical students altogether, and of the remaining four only admitted them without restrictions, the Government intended to intervene in any way so that those who accepted public money did not discriminate against one section of the public who contributed the money. Sir A. Mond said the question of the admission of students to university institutions was essentially for the discretion of the university authorities, with whose autonomy the Government desired to interfere as little as possible. The Government had no information indicating that the facilities for university education in medicine of qualified women were inadequate. Admission to the London Royal Free Hospital School of Medicine, which was also grant-aided, was wholly confined to women.

The Vaccination of Air Force Recruits.—Captain Gaest, in reply to Mr. Blomfield, on May 9th, said that recruits were not admitted to the Royal Air Force if they did not wish to be vaccinated. No man was forced to be vaccinated, but it was not possible to undertake the responsibility of accepting men for service who stated that they were unwilling to be protected against small-pox infection, especially as enlistment in the Royal Air Force involved an obligation to proceed, if required, to eastern countries, where unavoidable exposure to infection was common.

Lunatics in Chancery.—The Lunacy Bill, which was introduced in the House of Lords, and had been read in the Commons for the first time on May 1st, had second reading on May 9th. Its object is to amend the law as to Chancery inmates. In the first clause provision is made that a Master in Lunacy and an Assistant in Lunacy may act for two Masters in Lunacy. Clause II declares that the provisions of Sections 133 to 143 of the Lunacy Act, 1890, with regard to vesting and other orders, shall apply to criminal lunatics, and enable some small changes in property administration.

The Purity of Milk.—Mr. Doyle asked, on May 3rd, if the Minister of Health was aware that analysis and bacteriological examination of milk samples recently taken in Newcastle-on-Tyne showed that approximately 50 per cent. were seriously polluted. Sir A. Mond said he was aware of the results stated in recent reports of the M.O.H. for Newcastle. He hoped to introduce legislation to effect a substantial improvement in the milk supply of this country. Sir George Renwick asked if the Minister would send a Government analyst to verify or refute the serious statements made. Sir A. Mond said he would be very pleased to do so.

Ex-service Blind Pensioners.—Mr. Macpherson stated, on May 4th, in reply to Mr. Gilbert, that the blinded officers and men receiving All had been either at St. Dunstan's, where they had been trained in new occupations suitable to their conditions before returning to their homes. On their return the institutions mentioned continued to keep in touch with them through local representatives. These institutions were maintained out of private funds, and consequently the men had the advantage of receiving allowances at the maximum rate of pensions instead of the smaller allowances which would otherwise be payable.

Miners' Safety Lamps.—The question of the incidence of nystagmus was raised in a discussion on the motion for the second reading of the Coal Mines (Temporary Provisions of Safety Lamps) Bill on May 8th. Mr. Bridgeman, in asking the House to accept the measure, recalled that during the war the supply from Germany and Austria of glass for safety lamps for miners ceased, and the work had to be undertaken by British manufacturers. In the circumstances Mr. McKenna, on behalf of the Government, thought it right to guarantee to them that their trade should be maintained for them, even after the ending of the war. The present bill was to make amply secure the fulfilment of its pledge.

Mr. Adamson, for the Labour party, expressed doubt whether the British-made glasses fulfilled requirements, and wanted to know whether the increase in nystagmus could be traced to their use. Mr. Hopkinson suggested that spread of picture palaces had more to do with the disease than any miner's lamp invented. Mr. Bridgeman said he should not have introduced the bill if he had not been satisfied by severe tests that the lamp was effective. Sir Donald Maclean, however, suggested an adjournment in order to allow miners' representatives to consider the matter, and after some more discussion Mr. Bridgeman agreed to an adjournment.

Workmen's Compensation.—The Home Secretary, on May 3rd, accepted a motion by Mr. Walter Smith that in view of the unsatisfactory state of the law relating to workmen's compensation, and of the fact that the War Addition Acts expire at the end of the year, a Government bill to amend the Workmen's Compensation Act, 1915, should be introduced and passed during the course of this session. Mr. Shortt expressed the hope that after a round table conference the Government may be able to introduce a measure which will have the support of the great majority of both Houses. He said that either this must be done or the War Addition Acts must be included in the Expiring Law Continuance Act at the end of the session. Otherwise workmen would be limited under the old statute to £1 a week compensation, and the capital grant in the case of death would be only £300.

Answers in Brief.
Sir M. Barlow stated, on May 3rd, that female professional nurses for the sick were, as from July 1st next, excluded from unemployment insurance by the Act. Full details of the effect of this provision in particular cases should be submitted to the department for consideration.

Sir A. Mond has stated that the numbers of notifications of and deaths from tuberculosis in 1919 and 1920 in England and Wales were considerably less than in any previous year.

In reply to a question on May 3rd as to five deaths from starvation reported to have occurred in the county of Durham in 1920, Sir A. Mond said he was obtaining a special report. In 1920 the number of deaths from starvation or exposure in London was four, and in the provinces as a whole twenty-eight.

Mr. Macpherson states that there will be no alteration in the rates of ex-service pension and allowance specified in the second schedule in the Royal Warrant, before April 1st, 1923, and then only in accordance with the cost of living for the year 1922 as compared with the year 1919. He regrets to find that in some forms which have been issued the date April 1st, 1923, has been incorrectly printed as April 1st, 1927. All possible steps have been taken to correct this error.

A sum of £130,000 has been provided in the Estimates for 1922-23 to meet losses which may be incurred by local authorities in carrying out approved schemes for dealing with unhealthy areas. Such schemes have been put forward, or are under consideration, by a number of the larger local authorities, including the London County Council and the town councils of Manchester, Liverpool, Sheffield, Bristol, Leeds, Nottingham, and Exeter.

The Government intends to continue the system of State liquor trading in Carlisle, but not to extend it to other places at present.

INCOME TAX.

EFFECT OF BUDGET PROPOSALS ON INCOME TAX PAYABLE.

The following table has been calculated from the data contained in the Budget. It covers a range of incomes from £500 to £2,000, and distinguishes between (a) incomes wholly earned and incomes derived half from earnings and half from investments; and (b) between an unmarried person and a married couple with two children:

Incomes Wholly "Earned."

Income.	Single Persons.			Married Couples with Two Children.		
	1921-22.	1922-23.	Decrease.	1921-22.	1922-23.	Decrease.
£ 500	£ 61	£ 51	£ 10	£ 21	£ 23	£ 4
750	123	107	21	42	68	14
1,000	195	163	33	150	125	25
1,250	253	219	44	217	181	35
1,500	331	276	55	285	238	47
2,000	466	338	78	423	350	70

Incomes Half "Earned" and Half from Investments.

Income.	1921-22.	1922-23.	Decrease.	1921-22.	1922-23.	Decrease.
£ 500	£ 68	£ 57	£ 11	£ 28	£ 23	£ 5
750	140	117	23	94	78	16
1,000	211	176	35	165	138	27
1,250	282	235	47	235	197	39
1,500	353	291	59	307	256	51
2,000	495	413	83	450	375	75

Amounts calculated to nearest £.

The tables promised by the Financial Secretary to the Treasury to illustrate the effective rates of income tax (including super-tax) under the proposals of the Chancellor of

1922-23 have been issued by the Stationery Office in a White Paper, which can be purchased through any bookseller or direct from the Stationery Office, price 2d. net. (Cmd. 1652.) The White Paper contains three tables, the first applying to single persons, the second to married couples without children, and the third to married couples entitled to the allowance for three children. In each table the amounts and effective rates on earned and investment incomes are given and compared with the amounts and rates for 1921-22.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE annual general meeting of the London and Counties Medical Protection Society, Limited, was held at 12, Stratford Place, London, on May 3rd, when Sir JOHN ROSE BRADFORD, the President, occupied the chair. The annual report of the Council showed that the society, now entering on its thirtieth year, has made steady progress in all directions. During 1921 the number of fresh applications from members asking for advice and assistance was 465, and in the great majority of cases satisfactory results were obtained without recourse to litigation; the results in cases which did proceed to litigation were also, in the main, quite satisfactory. The surplus of income over expenditure in 1921 was £3,331, and the total surplus funds of the society amounted to close upon £30,000, while the total financial resources, including the amount reinsured with underwriters and the amount available by call on members, were nearly double this cash surplus. The number of new members elected during the year was 494.

Sir JOHN ROSE BRADFORD, in moving the adoption of the report, said that the amount of legal work during the year had been considerable, especially in respect to the cases which had been privately settled. This private settlement of cases was likely to be developed further. As they all knew, there was another society with similar objects and aims to their own, engaged in the work of medical defence, and as a result of communications between the two bodies it had been agreed that in the cases where one society was representing one individual and the other society another individual there should be a conference between the two societies before any actual legal proceedings were taken. There was something very obnoxious and unpleasant in the idea of one society of this kind representing one side of the case in court and a similar society representing the other side.

Dr. C. M. FEGEN, the Treasurer, seconded the adoption of the report, and said that the total membership of the society was now over 6,000. The financial resources were such that in the very improbable event of the society going into voluntary liquidation there would be a share-out of £5 a head, equal to five years' subscriptions. He remarked upon the excellent way in which the society was served by its permanent officers and staff.

The report was adopted unanimously, and it was also agreed, without dissent, to increase the amount available for the remuneration of members of Council for attendance at the meetings. In view of the appointment of a legal advisory committee which sits twice a month it was felt that attendance at this committee should be subject to the same recompense as attendance at the Council; accordingly the sum of 500 guineas was allocated for the remuneration of the directors.

Sir John Rose Bradford was re-elected President with acclamation, and the Vice-Presidents and members of Council retiring by rotation were re-elected, save that Dr. Owen Fowler, who has been a member of Council, was made a Vice-President, and Dr. Matthew W. B. Oliver elected on to the Council in his stead. Dr. Fegen was re-elected Treasurer, and Dr. Hugh Woods and Mr. A. G. R. Foulerton General and Financial Secretaries respectively, with expressions of appreciation for their past services.

THE seventh centenary of the University of Padua will be celebrated from May 14th to 17th. On May 14th the reception of the Italian and foreign representatives will take place at the University. On May 15th a grand ceremonial will be held in the Hall of Reason, and there will be a musical evening at the Verdi Theatre. On May 16th honorary degrees will be conferred in the hall of the University, and a banquet will be given by the municipality on May 17th. Other ceremonies and fêtes will be held at Venice.

Scotland.

VENEREAL DISEASE IN SCOTLAND.

A CONFERENCE of representatives of social organizations on the subject of venereal disease was held at Dundee on April 26th, with Dr. J. McGregor Robertson, chairman of the Scottish Committee of the National Council for Combating Venereal Diseases, in the chair. Sir Leslie Mackenzie delivered an address on the prevalence of venereal disease in Scotland. The data, he said, were so inadequate that there was no simple statistical way of conveying to the lay worker how much or how little venereal disease existed in any community. With the medical man there was no difficulty for if he was not always on the look-out for the presence of the effects of syphilis in hospital or in private practice it would not be long before he had cause to regret his want of alertness. The exact number of patients affected mattered less to him than that he should always be on the alert to make a correct diagnosis. From such information as was available the Royal Commission which reported in 1916 came to the conclusion that the number of persons infected with syphilis, acquired or congenital, could not fall below 10 per cent. of the whole population in the large cities, and the percentage infected with gonorrhoea greatly exceeded this number. If the figures of deaths from syphilis in Scotland, for the ten years 1910-19 inclusive, were taken, a total of 1,984 deaths was found, an average of nearly 200 a year; but when the details were examined it was found that the vast majority of those who died were children under one year suffering from congenital syphilis. Sir Leslie Mackenzie pointed out that general paralysis of the insane caused 2,520 deaths in ten years, an average of 252 per annum, and if it were assumed that in every hundred syphilitic persons three died of general paralysis of the insane, then 252 such deaths in Scotland would represent 8,400 persons affected with syphilis. As a provisional figure he put it that there were 9,000 new cases of syphilis every year in Scotland. He knew of no reliable index to the number of persons suffering from gonorrhoea, and all that could safely be said was that the number of such cases must be much greater than the number of syphilitics. Referring to the clinical reports made to the Scottish Board of Health for 1921, he observed that the new cases of all forms of venereal disease for the whole of Scotland were 13,676 in number, but if private practice were included as well as the official clinics there might be at least double that number. As compared with 1920, the figures for 1921 showed no great increase of cases, but they showed a great increase in the number of attendances, which meant that the work of the clinics was becoming better understood and appreciated.

DIFFICULTIES IN MEDICAL EDUCATION.

At a well-attended meeting of the Glasgow Medical Lunch Club, held on May 4th, and presided over by Dr. Charles F. Robertson, Professor Ralph Stockman was the guest of honour, and gave an address on the medical curriculum of the present day. He pointed out some of the difficulties in the way of an efficient medical education from the point of view of the student, and also those with which the teacher had to contend. He made particular reference, as was natural, to the teaching of clinical medicine and therapeutics. The two greatest difficulties at present were the overcrowding of the curriculum and of the classes, more especially those on the clinical side. The former difficulty was to a large extent the result of the gradual addition of special classes, attendance on which was now compulsory for purposes of qualification. This matter was at present receiving attention and consideration at the hands of the General Medical Council. The overcrowding of classes was a temporary difficulty which, so far as could be seen, would right itself within the next few years. Dr. Stockman's remarks were received with much attention, and the thanks of the members were voiced by Dr. James Hamilton. It was decided to hold the next meeting on June 8th.

EVOLUTION OF THE HUMAN INTELLECT.

The Morison lectures were delivered in the hall of the Royal College of Physicians, Edinburgh, on May 1st, 3rd, and 5th, by Professor G. Elliot Smith, F.R.S., of University College, London, on the subject of "The evolution of the

human intellect." Ho said that it was now half a century since the serious discussion of man's origin began, but during all that time there had been a strong reluctance on the part of the scientific investigators to attack the essential problem—how the human family came to acquire its chief distinction, the intellectual supremacy that differentiates man from all other living creatures. In 1859 Charles Darwin recognized the crucial importance of this problem; but since then it had been almost wholly ignored. Important discoveries of fossil apes, and equally significant researches in comparative anatomy had within recent years definitely established the main lines of the pedigrees of the human family right back to the dawn of the Tertiary period. This knowledge afforded a sure foundation upon which to base inquiries as to the nature of the factors responsible for each stage of progress from an insignificant and very primitive mammal like a jumping shrew, through the lemurs, lemuroids like the tarsier of Borneo and Java, the monkeys and the tailless apes, up to the ancestors of man himself. The essential factor in initiating this far-reaching process of intellectual development was the special cultivation of vision by a simple generalized arboreal animal. If the fuller cultivation of the sense of sight was the primary factor in differentiating the lemur from other mammals, it was the acquisition of stereoscopic vision that transformed one of the lemuroid group into an ape and determined the course of evolution of brain and mind which eventually brought about emergence of the distinctive characteristics of the human family.

The survival of the diminutive lemuroid *Tarsius* practically unchanged from the dawn of the Tertiary period was a particularly fortunate circumstance for the student of man's evolution. In the little tarsier itself stereoscopic vision had not been acquired, and special interest attached to this "living fossil" mainly because it just failed to attain the simian status. Its eyes were brought from the sides to the front of the head so that the animal was able to look forward both in the actual and the metaphorical sense of the word. The visual fields overlapped so that the images of the same object were impressed upon both eyes, and the range of co-ordinated movements of the eyes was increased by the dwindling of the nose and the flattening of the face. In *Tarsius*, for the first time among man's ancestors, sight definitely superseded smell as the dominant sense. In the course of transformation into the ape a complicated mechanism was built up in the brain, and there was a rearrangement of the optic fibres and a development of a particularly sensitive spot in each retina; these changes enabled the animal for the first time to see the world around it in the sense that we attach to the word "seeing," and it was able to appreciate form and size, colour, and texture, and position in space in a way not possible before. The focussing of the two eyes for the examination of an object represented the germ of attention and those powers of concentration that were essential for the growth of the mind. The acquisition of stereoscopic vision proved, therefore, a powerful stimulus for every part of the cerebral cortex, and the new meaning which things and events thus acquired enormously enhanced the biological value of the sense of hearing. The brains of the most primitive monkeys revealed a great extension in the area primarily concerned with hearing and a noteworthy increase in the skilled use of the voice to emit sounds. The growth of sensory discrimination and the continued development of skilled movements eventually gave an ape the experimental knowledge and understanding to devise and the muscular skill to use a complex acoustic symbolism as a means of communication with its fellows. Examination of the cranial casts of the Ape Man of Java and the Dawn Man of Pittdown revealed a precocious expansion of the part of the brain concerned with the appreciation of such auditory symbolism. This fact suggested that the acquisition of articulate speech was an essential factor in the transformation of an ape into a human being. The endocranial casts of the extinct types of mankind revealed the fact that this process of development was not completed when the human family came into existence. In the lower types of man the parts of the brain that were ill-developed were those that were concerned with attention, the finer sensory discrimination, and the more delicate manipulations. In the gradual expansion and filling out of the parietal, pre-frontal, and inferior temporal areas in the cerebrum, there was a hint of how the growth of man's brain and the acquisition of his distinctive intellectual powers had been effected.

England and Wales.

MEETING OF THE ASSOCIATION OF SURGEONS AT LEEDS.

The third annual meeting of the Association of Surgeons of Great Britain and Ireland was held in Leeds on May 4th, 5th, and 6th, and proved a great success. Out of a membership of 250, the attendance book was signed by no fewer than 181. Immediately before the meetings began on Thursday morning a graduation ceremony was held by the University for the conferring of the honorary degree of D.Sc. on Sir Harold Stiles, the retiring President, and a considerable number of the members of the association were present. The congregation of the University is mentioned elsewhere.

Sir Berkeley Moynihan was installed as President by Sir Harold Stiles, who vacated the chair. The three opening discourses were upon the subject of cholelithiasis. These were given by the President, by Sir Gilbert Barling, and by Mr. James Sherren, and were respectively on "The early symptoms and signs of gall stones," "The association of gall stones and pancreatitis," and "Cholecystotomy or cholecystectomy?" An adjournment of ten minutes took place before the discussion on these three addresses. On Friday morning short addresses were given by Mr. A. J. Conpland, who spoke on the surgery of the parathyroids; by Mr. R. Milne, whose subject was that of operations on the spine for tuberculous disease; and by Mr. Lockhart-Mummery, who dealt with a new method of treating ischio-rectal abscesses. On Thursday and Friday afternoons operations were witnessed in the new theatres of the General Infirmary. On Saturday morning demonstrations were given in one of the wards of the infirmary, at the medical school, and in St. George's House, the annexe to the pathological department. The dinner of the society was held at the Queen's Hotel, and was attended by 131 members and guests. The only speeches besides the two words which were used in proposing the toast of "The King" were that of Sir George Makins, who proposed the health of the President, and Sir Berkeley Moynihan's reply. Both speeches were of the highest standard. Sir George Makins carried his audience with him when, passing lightly over that with which every member of his audience was well acquainted—namely, Sir Berkeley Moynihan's eminence as a surgeon—he referred in felicitous terms to his tact, to his enthusiasm, to that which was his greatest characteristic, his success in bringing men together and promoting good fellowship.

The writer of these lines, himself a mere physician, begs to offer his cordial congratulations to the surgeons on the successful launching of this society. It is the first few years of a new society that leave their mark, and it cannot be said to be fairly launched till some time after its first meeting. Like Kipling's ship, it has to find itself, and this it is clear the Association of Surgeons has done.

LEEDS GENERAL INFIRMARY.

Consequent on the appointment of Mr. S. Daw as surgeon in charge of the orthopaedic department, which has been recently instituted, a vacancy has been created in the assistant staff. To this position Mr. E. R. Flint, F.R.C.S., has been appointed by the special election committee. Mr. Flint was a Leeds student, and for some years was resident surgical officer at the infirmary.

THE Governor of Illinois, U.S.A., has appointed a committee of medical men to investigate alleged irregularities relative to the issuing of licences and certificates by the State Department of Registration and Education.

THE eighteenth South African Medical Congress will be held this year at Johannesburg, from September 18th to 23rd. The presidents of the different Sections are as follows: Medicine, Dr. Aylmer Dumat; Surgery, Dr. E. C. Long; Obstetrics and Gynaecology, Dr. Bruce Bays; Public Health, Dr. J. J. Boyd; Special Subjects, Dr. H. Symonds. A new departure has been made by arranging that at general meetings a paper shall be read on a special subject, but of a character likely to render it of general interest. These papers will include such subjects as: ulcer, malaria, of the eye. The business meeting is held on the Monday and the sections on the Tuesday, Wednesday, Thursday, and Friday.

Correspondence.

BABIES' WEIGHTS.

SIR,—May I ask your courtesy in recording the fact, which may interest those of your readers who are concerned with infant welfare, that this laboratory has just issued two revised charts of babies' weights, one for males and one for females. They may be obtained from the Cambridge University Press, Fetter Lane.

The weights are those of a large number of babies of artisan parents, and were provided for us by the baby clinics of a large manufacturing town. They indicate (1) where the baby of given age and given weight stands among babies of that age, and further (2), on the basis of this weight, a prognosis of what its health will be at the end of its first year of life.

Of course, weight is not the only factor in the health of the baby, the correlation between health and weight being less than 0.5, but the charts will suffice to indicate all that can be learnt from the factor weight alone.

In the case of individual babies, it would be very useful to plot their weights on these charts, and so ascertain whether their grade is improving, and the prognosis bettering. This would be valuable when the baby belongs to a different social class.

Existing baby charts contain, I think, much less information, and that of a somewhat antiquated character.—I am, etc.,

KARL PEARSON.

Galton Laboratory, University of London, May 4th.

"ALASTRIM" OR "PARASMALLPOX."

SIR,—In the BRITISH MEDICAL JOURNAL of April 29th, 1922, Dr. J. Johnstone Jervis, Medical Officer of Health, Leeds, deplors the introduction into medical nomenclature of the word "alastrim," which he says is "supposed to signify small-pox of a mild type." He goes on to say:

"Already the use of this silly word is beginning to cause confusion in the lay mind, and as it is quite superfluous I would earnestly appeal for its utter banishment."

The point raised by Dr. Jervis is one of considerable practical importance, about which we are likely to hear a good deal more in the near future. Confusion on this matter is unfortunately not confined to the lay mind. Many medical minds have not yet grasped the fact that alastrim is not "small-pox of a mild type," but a separate entity distinguishable clinically from chicken-pox on the one hand and from small-pox on the other.

The present position with regard to small-pox and alastrim presents a striking analogy to the position in the early days of the war with regard to typhoid and paratyphoid fevers, when paratyphoid fever was regarded by some observers as "typhoid fever modified by inoculation." Paratyphoid fever is a distinct disease resembling typhoid fever in its clinical manifestations, but generally milder in its course and having a case mortality of 2 per cent. or less instead of the case mortality of 10 per cent. or more in typhoid fever. So in the case of alastrim we have a disease resembling small-pox in its clinical manifestations but generally milder in its course, with a case mortality of 1 per cent. or less as against 20 per cent. or more in the case of small-pox.

Where the analogy breaks down is in regard to immunology. Inoculation against typhoid fever produces no immunity against paratyphoid fever, but it would appear that vaccination against small-pox produces immunity against alastrim. This can be explained on the hypothesis that the viruses of small-pox and alastrim each contain two antigens, one of which is common and capable of producing immunity to both diseases.

If "alastrim" (synonyms amaas, milk-pox, Kaffir-pox, etc.) is a disease separate and distinct from small-pox, it should have a distinctive name. If "alastrim" or "amaas" are unsuitable names, why not call it "parasmallpox"? No useful purpose can be served by pretending that it is small-pox. It might be suggested that to call it small-pox would induce people in the areas where the disease is epidemic to submit to vaccination. That subterfuge might, however, defeat its own object—for the antivaccinators would naturally retort, "If small-pox has lost its power to kill and disfigure its victims, why trouble about getting vaccinated against it?"—I am, etc.,

R. P. GARROW,
Medical Officer of Health.

Westfield, May 6th.

"THE COMPOSITION OF SCIENTIFIC PAPERS."
SIR,—In your issue of April 29th (p. 691) you are good enough to commend a small book of mine on the *Composition of Scientific Papers*. The second edition was exhausted before the war, and since that time delays have been pouring in from many sides, and I am now engaged on a revision of this handbook, which I hope Messrs. Macmillan will be able to republish in a few weeks.—I am, etc.,

CLIFFORD ALLBUTT.

Cambridge, May 3rd.

THE GENERAL PRACTITIONER AND THE HOSPITALS REPORT.

SIR,—After reading the report on the organization of voluntary hospitals and the correspondence thereon a sincere doubt arises as to whether the general practitioner realizes the effect this policy will have on his practice. The report is on voluntary hospitals, but no definition of the word "voluntary" is attempted; in fact, it is deliberately evaded. It is evident, however, that the hospitals have now ceased to be what they were originally—namely, charitable institutions. In addition to the free (indigent) or charity patients they may now admit two groups—namely, the tariff and the private patient. I hold no brief for nursing homes, but I should think the proprietors of these homes will have some objection to the competition of hospitals in their business. I am more concerned with the group of tariff patients, which includes—

"All those paid for by Public Authorities, Approved Societies, Employers of Labour, Insurance Companies or other bodies or under any contributory scheme" (para. 19 (c)).

"Payments made for Tariff In-patients should be for work done based upon a tariff of fees agreed upon from time to time by the contracting parties" (para. 22 (a)).

It is quite clear under these provisions (1) that hospitals through their governing boards may now make contracts with any person or body of persons; (2) that this contract includes the provision of treatment; (3) that the contract may be made without consulting the medical staff, or the local profession as represented by the British Medical Association. This is contract practice with a vengeance! A few weeks ago we were trying to impress the Minister of Health that we could not under any circumstance discuss terms of service with approved societies. Now we have gone to the other extreme, and allow lay boards to arrange our fees for us with anyone or everyone. Such contracts being made, it is certain (whatever pious resolutions may be passed to the contrary) that individuals who contribute to the tariff system will now claim hospital benefit as a right, and hospitals will be compelled, and will find it to their interests, to provide accommodation for them.

Apart from an income limit, the efficacy of which is open to grave doubt, the only condition which has to be observed in the admission of patients is that the case "should be a suitable one for hospital treatment." Is it forgotten that very many cases suitable for hospital treatment are equally suitable for home treatment? It may be news to the Hospitals Committee that a fair proportion of the income of a general practitioner is derived from operations and other treatment now provided by hospitals, but in face of hospital competition what chance will he now stand of obtaining this private patient beside the question of saying that "no tariff patient should be admitted without the recommendation of a private practitioner." If a patient has a title to hospital benefit his private attendant will find some difficulty in persuading him to have the treatment at home.

It is inconceivable that the British Medical Association should formally approve of a scheme of contract practice which will do so much harm to private practice, both general and consultant; but assuming for a moment that it does, it is not too much to expect that it will apply to it the same principles for which we fought so strenuously in 1911. These were mainly three:

1. No negotiation with societies.
2. Adequate remuneration.
3. Free choice of doctor.

With the first point I have already dealt, but in regard to adequate remuneration it is seriously asserted that a man with an income from £250 to £350 a year cannot pay for hospital treatment apart from maintenance? I have said that private practitioners are now getting reasonable fees for home treatment, and I venture to state that under a scheme

of insurance a premium of 1s. to 2s. per annum would provide an ample sum out of which adequate fees for treatment could be paid. The question of free choice of doctor is admittedly difficult in large hospitals, though a panel system is not impossible, but in the smaller towns the hospitals are staffed by general practitioners. What reasonable objection could be advanced in the latter case to allowing outside practitioners to treat their own patients in the local hospital if they so desired? Already they have to submit to their patients being treated by men who are possibly in keen competition with them, but if to this is added the loss of an appreciable source of income they may well condemn the hospitals. Let us hope that the Representative Meeting will come to the rescue of the profession in time.—I am, etc.,

Bury, May 4th.

J. C. TURNBULL.

SIGHT-TESTING OPTICIANS AND PRESBYOPIA.

SIR,—In the *Bristol Medico-Chirurgical Journal* for December, 1921, appears an article by Mr. Cyril H. Walker, entitled "Some phases of quackery in relation to diseases of the eye." In alluding to the question of sight-testing by opticians he expresses an opinion which should not be allowed to pass unchallenged. Mr. Walker states:

"Indeed, it seems obvious that a certain amount of testing for spectacles cannot be objected to. Why should not a presbyope of 50 buy a pair of spectacles without consulting a doctor, just as he would buy a pocket magnifying glass, or any of the appliances which mitigate the disabilities of advancing years? Presbyopia is not yet a notifiable disease, in fact it is hardly a disease at all. Neither the public nor the profession is likely to suffer much at the hands of the sight-testing optician, provided he knows his trade and is honest. But the possibility of his overlooking glaucoma, optic neuritis, or other eye diseases is considerable. The public should be warned of this and have the opportunity of getting proper advice at a cost that is within their means."

In fairness to Mr. Walker I have quoted his remarks at some length, and it should be added that he goes on to urge a State-medical service ensuring the provision of a sufficient number of well-staffed and properly equipped ophthalmic clinics where the public may have the opportunity, as he has stated, of getting proper advice at a cost that is within their means.

What I take exception to is his query, "Why should not a presbyope of 50 buy a pair of spectacles without consulting a doctor, etc.?" In my opinion the management of presbyopia is a question that in the past has received too little attention; not only on the part of medical practitioners in general, but even of a considerable number of ophthalmic surgeons of standing. It is a common experience to observe ophthalmic surgeons spending much time and trouble in estimating the static refraction of a patient, and then, inquiring his or her age, making an addition of an arbitrary amount for near work. The correction of presbyopia too long has been a matter of mere rule of thumb. The average sight-testing optician, as often as not, does not worry to estimate first of all the static refraction; indeed he has not the time and very often not sufficient skill to do this. Rather does it happen that a selection of reading glasses is offered to the customer, and it is the latter who makes the final choice. In my experience the patient who has bought a pair of spectacles for near work from an optician invariably is using too strong a pair. The result is to cause undue approximation of the artificial near point; thus throwing unequalled strain on the muscles of convergence which ultimately leads with advancing years to marked deficiency of convergence power and resultant difficulty in maintaining a reasonable reading distance. A considerable proportion of one's patients above the age of 60 who complain of inability to read for long are found to suffer from convergence deficiency, which in my opinion at least is attributable to the habitual use of too strong reading glasses dating back to the time of onset of presbyopia.

The correction of presbyopia is not to be treated lightly. Time and exactitude in detail are demanded from the ophthalmic surgeon, whose duty it is to examine carefully and treat every case on its merits. The static refraction must be determined, unsele balance investigated, and power of accommodation carefully estimated before any attempt to prescribe glasses is made. With these data before him the surgeon should ascertain at what distance the patient desires to read or work, taking into account his height, length of arms, and habitual posture, and then, and then only, work out the required correction. Apart from the question of overlooking diseased conditions, such as glaucoma, etc., I maintain that far more harm than good is done by the average optician.

Mr. Ernest Clarke, in a recent article, states: "My long experience has taught me that the correct treatment of presbyopia is one of the most important duties of the oculist. We are dealing with patients who are arriving, or who have arrived, at a critical period of life." Bearing this in mind, it behoves every medical man who has the welfare of his patients at heart to advise them, if they possibly can, to consult an ophthalmic surgeon when the stage of presbyopia is reached, and not to look upon the matter in the light of buying a pair of binoculars.—I am, etc.,

Cape Town, March 29th.

ALAN W. SICHEL.

MEDICAL OBSERVATIONS IN ALBANIA.

SIR,—During a recent discussion before the Royal Society of Medicine reference was made to the work of Colonel McCarrison in the Himalayas, where he found an absence of several of our most prevalent diseases.

In this connexion it may be worth while to record our experience in Albania. During the past year I examined, operated on, treated, or prescribed for, 20,133 patients who attended the Ambulance of the White Cross at Sentari. The negative findings were no less interesting than the positive. There was one case of carcinoma. Among this large number of patients I found no case of appendicitis, no case of hypertrophied tonsils or turbinates, and no case of adenoids.—I am, etc.,

Sentari, Albania, April 16th.

FRED. E. BURNHAM,
Brigadier-General.

VACCINES IN WHOOPING-COUGH.

SIR,—The interesting paper by Drs. Paterson and Smellie (*BRITISH MEDICAL JOURNAL*, May 6th, p. 713) bears out the experience I have obtained with vaccines, that they are valueless as curative agents in whooping-cough. As prophylactics they are practically infallible; but the larger doses of 2,000 million must be injected at two days' interval, before the seventh day of contact. One can then almost guarantee that the patient (child or adult) will not suffer from the disease.

As a curative agent we have nothing better than intramuscular injections of ether, 2 c.cm. every other day for babies and 3 c.cm. for children 4 years of age and onwards. Three or four injections should suffice. It is wonderful the influence it has over the established disease—spasms, vomiting, etc., ceasing sometimes spontaneously.

The diagnosis of whooping-cough is very simple for those who know how to do a simple white blood count.—I am, etc.,

Bogor, May 8th.

JULES F. REX.

SUN OR AIR?

SIR,—Under the above heading Dr. A. C. Deveroux, in the *BRITISH MEDICAL JOURNAL* of March 18th (p. 456), referring to the relative values of sunlight and open air, concludes: "The cooling power stimulates metabolism and cures disease. It doesn't matter a great deal whether the sun is shining or not." May I mention an experience regarding their relative values? During the epidemic of diphtheria in the Orange Free State during 1890-91 I had many cases of the disease under my care, and when possible I had them put in the open air under a white tent, or in the room of the house most exposed to the sun. I found this a great aid to recovery. During damp, cloudy weather improvement was distinctly retarded. So marked was the value of bright, sunny days that I concluded that the sun's rays had the power of aiding in the destruction or elimination of the toxins of the disease. While in Britain in 1892 I tried to get some explanation of this seemingly beneficial action of sunlight in these cases, but failed to do so.

My experience, therefore, was that the sun's rays had in these cases a value additional to that of open air and independent of it.—I am, etc.,

Clocolan, O.F.S., April 13th.

B. G. BROCK.

REDUCTION OF MEDICAL FEES.

SIR,—I am sorry to read in his letter of April 9th that Dr. Ellis did not intend his previous letter, published on April 1st, for a joke. Since this is the case I am pleased that he admits I have voiced a grievance, but I do not agree that most of my facts were beside the mark.

I gathered from Dr. Ellis's original letter that when the cost of living was at high-water mark, fees were increased 50 per cent.; and since the cost of living is commencing to

(all he wishes us to reduce our fees. I tried to show reasons why we should not reduce our fees yet—namely:

1. The cost of living is still more than 50 per cent. above the pre-war cost.
2. Pre-war fees in many cases possibly may not have been just recompense, when the conditions which we have to fulfil are considered.
3. There is now a class of men in the profession who deserve a little consideration from their senior colleagues.

The fact which Dr. Ellis seems to fail to grasp is that although the cost of living is well above 50 per cent. more than pre-war cost of living, fees are simply 50 per cent. above pre-war fees.

I know nothing of the type of practice run by those who feel they ought to agitate for smaller fees, but I am writing simply from the point of view of a panel practitioner with his minimum fee of 2s. 6d. a visit and 3s. 6d. a bottle of medicine (viii) in his private practice. I have seen non-panel, non-dispensing practices with a minimum of something like 7s. 6d. a visit, but popular practitioners who can hold fashionable practices of that sort can adjust their fees to what they know they can command without writing to the JOURNAL. There are only two or three of these practitioners to scores of the less fortunate, and are not many of their patients drawn from a class who would scorn to have seen calling on them a man who was known to have a panel? Therefore need they fear the competition of their colleagues? I think not. It is time, however, that we members of the poorer paid majority commenced seriously to give our united consideration to the subject of fees. A little more enthusiasm must be shown or misunderstandings will arise and individuals may accept fees incompatible with the dignity of professional man who has undergone a strenuous and costly training.

Regarding the reasons under heading No. 1—because we failed to raise our fees in proportion to the rise in the cost of living, and were so late in raising them the little we did, surely is no reason why we should be in so great a hurry to reduce them. Look also at the cost of running a practice now. Pre-war petrol 10d. a gallon, now 2s. 5d., lubricating oil similar, motor insurance premiums still rising, and, oh! the tax on a Ford car. These things also reduce our net income.

The reasons under No. 2 I shall pass over as stated in my letter of April 1st: but regarding those under No. 3 I would say: Now is the time a little practical sympathy is needed by those in this class who recently have bought practices at post-war valuation, to have their panel fees decreased, and then to find an agitation being set on foot to reduce their private fees. Should gross incomes be reduced to the pre-war figure, or even below the standard of the present cost of living before there are any reasonable grounds for it, the net incomes are going to be greatly diminished, since living and practice expenses are both at a higher percentage above pre-war figures than are the fees. However, the man who purchased or already possessed a practice in 1917 or early 1918 will not have these worries so acutely.

So far as a comparison with civil servants goes, they are not alone in receiving attention from the Government, for has not the panel fee been reduced? Panel practitioners receive no pension.

I quite agree that it would be dishonest to get a large fee under false pretences, so when the cost of living falls to 50 per cent. above pre-war costs, let us reconsider our fees in relation to the value of our services and our expenses. I suggest a minimum not lower than 2s. 6d. a visit and 3s. 6d. an 8-ounce bottle of medicine.—I am, etc.,

Standish, Lancs, April 25th.

T. WILSON SHAW.

THE NAVAL MEDICAL SERVICE.

SIR,—Medical officers who joined the navy, as I did, in 1894, did so, according to an official Regulation that fleet surgeons—that is, surgeon commanders—would be compulsorily retired at the age of 55.

According to an Order in Council of July, 1919, I understand some 100 of these officers are being gradually compulsorily retired before this age and without any compensation. If this be so, it seems to me the Admiralty are perpetrating a gross injustice.

The majority of officers of this age may be expected to be married men with families; their pension is naturally much less than their full pay, and it is very difficult for them to get a job in our crowded profession. I understand it was authori-

tatively stated recently in the House of Commons that to summarily discharge regular officers who joined the service as a life profession would be contrary to all ideas of justice; how can this statement be reconciled with the present action of the Admiralty? I could enter with more detail into the question, but until their lordships show some disposition to consider it, it would be waste of my time and your valuable space.

As in times past, I feel sure the Naval Medical Service can rely on the help and sympathy of the British Medical Association.—I am, etc.,

Sevenoaks, April 16th.

GERALD SICHEL.

Our correspondent cannot be aware that the British Medical Association, as recorded in our columns, has for some time past been in communication with the Admiralty on behalf of the senior surgeon commanders who were retired before the time anticipated when they joined the service. The Naval and Military Committee has pressed the Admiralty to reconsider this matter, and it is understood that a decision may be expected soon. A further statement will appear in the JOURNAL, when this can be done without prejudicing the position.

A STANDARD ENGLISH CATHETER GAUGE.

SIR,—The necessity for a standard English catheter gauge has been recognized for many years past, but the fact that the English catheter gauge has been so firmly established throughout the English-speaking world has hindered the adoption of any change. The gauge at present in use has generally been known as Weiss's gauge, and it appears to have been gradually built up by that firm from the early days of the last century, starting with one size (No. 8), smaller and larger sizes being added from time to time; but the gradation between the sizes has not been exactly uniform.

The difference between each size is based on sixty-fourths of an inch, but there is a deviation in two or three of the sizes. Other makers in producing gauges have also based them on sixty-fourths of an inch, but the deviations have not been in agreement with those on Weiss's gauge. Further, in the course of time some of the gauges in use have become worn, and there has been no generally adopted standard for remedying the variations.

This association has had the matter under consideration for some time, and has now adopted the new gauge, which shows very little deviation from the original gauge of Messrs. Weiss, but possesses the advantage of having an equal gradation between the sizes and a definite relation to the French gauge.

Dealing with the sizes in common use, No. 1 of the new gauge is equal to 1.5 mm. diameter, each size increasing by 0.5 mm. to No. 12, which equals 7 mm. diameter. There are two sizes smaller than No. 1—namely, No. 00 = 0.5 mm. diameter, and No. 0 = 1 mm. diameter; and with regard to the larger sizes No. 13 = 7.5 mm. diameter, each size above this increasing by 0.5 mm. diameter to No. 30, which equals 16 mm. diameter. The complete range runs from No. 00 to No. 30, with a uniform gradation of 0.5 mm. between each size, thus covering all the usual sizes for urethral instruments, the larger sizes serving also for oesophageal instruments.

Table showing Diameters in Millimetres.

No.	Diameter.	No.	Diameter.	No.	Diameter.
00	0.5 mm.	10	6.0 mm.	21	11.5 mm.
0	1.0 "	11	6.5 "	22	12.0 "
1	1.5 "	12	7.0 "	23	12.5 "
2	2.0 "	13	7.5 "	24	13.0 "
3	2.5 "	14	8.0 "	25	13.5 "
4	3.0 "	15	8.5 "	26	14.0 "
5	3.5 "	16	9.0 "	27	14.5 "
6	4.0 "	17	9.5 "	28	15.0 "
7	4.5 "	18	10.0 "	29	15.5 "
8	5.0 "	19	10.5 "	30	16.0 "
9	5.5 "	20	11.0 "		

—I am, etc.,

G. R. CHEESMAN,
Honorary Secretary, Surgical Instrument
Manufacturers' Association.

London, E.C.1, May 1st.

SLIPPING RIB.

SIR,—In reference to the discussion on "slipping rib," may I point out that the tenth rib is not the only one that slips? In patients complaining of neuralgic pain in the front of the chest I always examine the back, over the site of the heads of the ribs, and frequently find a tender spot on a rib-

head corresponding to the site of the pain in front, and due to pressure from a twisted rib on the intercostal nerve at the back causing referred pain at the end of the nerve in front.

In such cases I get the patient to lie on the chest, and exercise a sudden sharp pressure over the head of the rib with the base of my hand, and often hear a click, meaning the reposition of the rib. Instantaneous disappearance of both pain and tenderness follows on this manoeuvre, and the patient is much impressed with the rapid relief.—I am, etc.,

London, W., April 19th.

H. FERGIE WOODS.

VAN DEN BERGH TEST IN JAUNDICE.

SIR,—An error has crept into my article on the use of the van den Bergh test in cases of jaundice, which was published in your issue of May 6th. The mistake occurred in the retyping of my own manuscript, and I regret that it escaped my notice. It concerns the making up of the standard solution of iron sulphocyanide for the colorimetric test. Two sentences have been mixed up and shortened into one; the first paragraph of the method of preparation should read:

"Dissolve 0.1503 gram of ammonium iron-aleum in 50 c.c.m. concentrated HCl, and add water to 100 c.c.m. This gives a dilution of 1 in 320 normal, which keeps indefinitely. To 10 c.c.m. of this solution add 25 c.c.m. concentrated HCl, and water up to 250 c.c.m. This gives a dilution of 1 in 8,000 normal, which will keep for about six months."

The account of the colorimetric method was given with great brevity, and those who intend to use it are again recommended to look up the full technical details as given by van den Bergh in the *Presse Médicale*, June 4th, 1921, and in his monograph. The serum tested is diluted both by the addition of alcohol and of the diazo reagent, and this dilution must of course be taken into account in estimating the number of "units" of bilirubin present in the serum.—I am, etc.,

University College Hospital, May 9th.

J. W. McNEE.

Obituary.

JAMES MIDDLEMASS, M.A., B.Sc., M.D., F.R.C.P. EDIN.,

Medical Superintendent, Sunderland Borough Mental Hospital.

THE death, on May 2nd, of Dr. James Middlemass is not only a serious loss to his own special sphere of psychological medicine but to the medical profession in general, for he took much interest in the affairs of the profession, was twice president of the Sunderland Division of the British Medical Association, and during the war was chairman of the Local Medical War Committee. His independent position gave him, perhaps, special advantages in dealing with medical problems, while his tact as a chairman and his ability to direct discussion and obtain a decision frequently proved of great value.

Dr. Middlemass, who was aged 59, was a native of Edinburgh. After taking the degrees of M.A. and B.Sc., he graduated M.B., C.M. (with honours) at Edinburgh University in 1883 and proceeded M.D. in 1898; he became F.R.C.P. Edin. in 1896. He studied also at Strasbourg and elsewhere abroad, and after a period as resident physician at the Edinburgh Royal Infirmary he became resident pathologist, and later assistant physician, to the Royal Edinburgh Asylum, Morningside. In 1898 he was appointed medical superintendent of Sunderland Borough Mental Hospital, Ryhope, and in 1918 he was appointed lecturer in psychological medicine at the College of Medicine, Newcastle. Dr. Middlemass married the sister of Dr. Elkins, his predecessor at the Sunderland Mental Hospital, and he is survived by his widow, a son, and a daughter; his son is a B.Sc. in agriculture of Edinburgh University and holds an appointment in Scotland.

Dr. BEDFORD PIERCE writes: Dr. Middlemass's illness was altogether unexpected; an attack of appendicitis occurred when on holiday, and septic troubles developed, so that several operations were necessary; he succumbed after a wearisome illness of over three months. On May 5th a remarkable memorial service was held at Ryhope parish church, attended by representatives of the Sunderland Corporation, large numbers of the medical profession, the staff of the Mental Hospital, and many others. It was a striking tribute of respect and affection. Dr. Middlemass wrote many articles to the medical journals, chiefly relating to pathology. Latterly he greatly assisted in preparing the *Handbook of Mental Nursing*, published by the Medico-Psychological

Association. He was an active member of the committee now engaged in rewriting the *Handbook*, and though the names of the writers of the sections are not published, it may be said that Dr. Middlemass's assistance in this work, which is of such great importance to mental nurses and their patients, is recognized by the committee to be of the utmost value. In this way his personal influence will be felt by many generations of mental nurses yet to come. His lectures on mental disease at the Newcastle medical school were clear and impressive, and were most successful. In regard to his work at Sunderland the chairman of his committee has stated that he has never known an official in whose judgment they had so much confidence. He was beloved by his staff, who recognized his justice and his sympathy. Dr. Middlemass was essentially Scottish; he was quiet, cautious, and reserved, of very decided opinions, and possessed of deep religious convictions. He was a versatile man, proficient in modern languages, and he played the cello. Dr. Middlemass spent himself for others in no ordinary way, and "having served his generation faithfully, by the will of God, he fell asleep."

WE regret to record the death of Dr. C. SOMERTON CLARK, which took place in King's College Hospital on April 6th at the age of 46. He was born at Burgess Hill, Sussex, and educated at Dean Close School, Cheltenham. He graduated in Edinburgh as M.B., Ch.B. in 1899, became F.R.C.S. in 1901, and took the course at the London School of Tropical Medicine in the same year. He was house-surgeon to Hove Hospital 1899-1900. In 1902 he sailed for India to work in the Punjab Mission of the Church Missionary Society; he held positions successively at Srinagar, Amritsar, Dera Ismail Khan, and Quetta. He only took one furlough (in 1909), and in 1919 was invalided home with splenic leukaemia. The greater portion of his time had been spent in unhealthy stations on the plain, and one of his last suggestions was that a scheme should be introduced obviating the necessity of keeping men in the unhealthy stations for too long a period by a rotation system of transfers in their location. This was very characteristic of the man, who was always thinking and planning for other people, and the first to sacrifice himself for their benefit. He did much to bring the Dera Ismail Khan Hospital to a high state of efficiency, and the strain in that difficult and trying district may indeed have predisposed to the illness which he subsequently developed. He was always *persona grata* with his patients and beloved by little children. His sympathies were broad and his Christian influence wide-reaching. From time to time he contributed articles to medical and missionary periodicals, and he will long be remembered by a wide circle of friends in India and in England. For the past three years his health had been very seriously impaired, and he knew from the nature of his disease that there was little hope of improvement or recovery. Much sympathetic help and advice were received from the late Sir W. Osler and other eminent members of the profession, and nothing could have exceeded the kindness and skilful care with which he was treated at King's College Hospital. For many months remarkable results followed the use of x rays, and recently, when they ceased to be beneficial, radium was employed with advantage, but a febrile attack precipitated the end.

Dr. SAMUEL JOHN BROOKS, who died in his 62nd year at Over Huddon, near Bakewell, on April 13th, was until October last in practice at Eyam, where he held the appointments of medical officer to the board of guardians and to the isolation hospital. He was the eldest son of the late Dr. R. W. T. Brooks, of Serjeant's Inn, and was educated at King's College School and King's College Hospital, London, where he studied under Lord Lister. He obtained the diplomas of M.R.C.S. and L.S.A. in 1885. Before he settled in Eyam he had practised for some time at Mossley, near Manchester, where he married the daughter of the late Dr. J. K. Seville. Dr. Brooks was well known as a lover of horses, and always carried on his practice with the assistance of one or two well-chosen animals, often of his own breeding. His death after a short period of retirement is mourned by a large circle of friends and old patients. He was an old member of the British Medical Association.

Dr. ARTHUR EDWARD WILSON died suddenly at his residence at Sydenham on April 24th. He was educated at Boston Grammar School, and won an open scholarship in natural science at St. Thomas's Hospital, London, where he

Colonel Francis Warburton Begbie, C.B.E., Army Medical Staff (retired), died at Exmouth, after a long illness, on April 23th, aged 57. He was the eldest son of the late Dr. James Warburton Begbie, and was born in Edinburgh on June 13th, 1864. He was educated at St. Bartholomew's Hospital, and took the M.R.C.S. and L.R.C.P. Lond. in 1890. He entered the army as surgeon-captain in July, 1891, became colonel in 1917, and retired on January 1st, 1920. He served on the North-West Frontier of India in the Chitral campaign of 1895 (medal with two clasps), in the South African war of 1899-1902, taking part in the Orange River Colony, and Cape Colony, Natal, the Transvaal, the Tugela Heights, Spion Kop, Vaal including the actions of Colenso, Tugela Heights, was mentioned in dispatches in the *London Gazette* of April 16th and November 15th, 1901, and received the Queen's medal with six clasps and the King's medal with two clasps. During the early part of the recent great war he was Commandant of the R.A.M.C. training

Medical News.

THE fourth lecture of the series on pathological research in its relation to medicine, arranged by the Institute of Pathology and Research, St. Mary's Hospital, Paddington, will be delivered on Thursday, May 18th, by Major-General Sir W. B. Leishman, F.R.S., who will speak on enteric fevers in the war. On May 25th Professor E. H. Starling, F.R.S., will discuss some new experiments on the kidney. Sir A. C. Houston will deal with the purification of water on June 1st, and Professor W. Bulloch, F.R.S., will discuss the historical development of the doctrine of group and diphtheria on June 8th. The series will be brought to a close by a lecture on diverticula of the alimentary tract by Sir Berkeley Moynihan, to be given on June 15th. The lectures, which are given at 5 p.m., are open to all members of the medical profession, and to all students in medical schools, without fee.

THE next post-graduate lecture in the new series arranged by the Fellowship of Medicine will be given by Sir Thomas Harder at the house of the Royal Society of Medicine on Tuesday next, May 16th, at 5 p.m., on "The clinical significance of hæmoptysis." The lecture is open to members of the profession. The course of six practical demonstrations on gastro-intestinal affections in children, skin diseases, the Wassermann reaction and its importance in general practice, will be given at the "Children's Clinic," Western General Dispensary, on Mondays and Thursdays, at 4.45 p.m., commencing on May 15th. The fee for the course is one guinea; application for copies of the syllabus and tickets should be made to the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W.1.

AN interesting ceremony took place at the annual dinner of the Laryngological Section of the Royal Society of Medicine held on May 5th, when the Section was presented with a presidential badge by Sir William Milligan, M.D., President of the Section. The badge, which is the work of the Goldsmiths and Silversmiths Company, is in gold and enamel with a centre medallion representing the profile of Signor Manuel Garcia, the "Father of Laryngoscopy."

THE summer session of the West London Post-Graduate College, Hammersmith, opened on May 8th, and will continue until July 15th. There will be a lecture or demonstration every day except Saturdays at 5 p.m., and demonstrations will be given daily in the medical and surgical out-patient rooms and the special departments at 2 p.m. Special demonstrations on the cases in the wards will be given by the physicians and surgeons, and a number of lectures and demonstrations on special subjects have been arranged. Particulars of the courses and special classes may be obtained from the dean of the college, Dr. Arthur Saunders. The fee for attendance on the hospital practice, including all ordinary lectures and demonstrations, is 4½ guineas for one month, 6 guineas for six weeks, or 9 guineas for three months.

DR. REDMOND ROCHE has been chosen as President of the Society of Members of the Royal College of Surgeons of England, in succession to Dr. J. Brindley-James, deceased.

A SPECIAL course of six lectures on advanced surgery will be given in the surgical unit of the London Hospital on Fridays at 4.15 p.m. in the clinical theatre. On May 12th and 19th Mr. Russell Howard will discuss acute intestinal obstruction, on May 26th Sir Hugh Digby will speak on carcinoma of the rectum, on June 2nd Mr. Robert Milne will deal with operative treatment of spinal caries, and on June 9th and 16th Mr. Hugh Lett will discuss hæmaturia and painful micturition respectively. The course is open to graduates and senior students.

AT a meeting of the Association of Economic Biologists to be held at 2.30 p.m. on Friday next, May 19th, at the Imperial College of Science, Professor J. H. Priestley of Leeds will give a demonstration of the toxic action of illuminating gas on plants.

THE annual summer dinner of the Glasgow University Club, London, takes place in the Trocadero on Friday, May 26th, at 7.15 for 7.30 p.m. precisely, Sir Archibald Denny, LL.D., in the chair. All Glasgow University men who wish to attend are requested to apply without delay to the honorary secretaries, 1, Harley Place, N.W.1.

THE next meeting of the Medico-Psychological Association of Great Britain and Ireland will take place on Thursday, May 25th, at 11 a.m., at 11, Chandos Street, Cavendish Square, and at 3 p.m. at the L.C.C. County Hall, Spring Gardens, under the presidency of Dr. C. H. Bond. Sir Frederick Mott will read a paper on the genetic origin of dementia præcox at 11.15 a.m., and Sir Maurice Craig will deliver the third Maudsley lecture at 3 p.m. on some aspects of education in relation to mental disorder.

THE Aberdeen University Club, London, will hold its bi-annual dinner on Thursday, May 18th, at Gatti's Restaurant, Strand. Dr. W. A. Milligan, the honorary secretary, 11, Upper Brook Street, W.1, will be pleased to hear from any members wishing to be present, and also from graduates (men or women) wishing to join the club.

A MEETING of the West Kent Medico-Chirurgical Society will be held at the Miller General Hospital, Greenwich, to-day (Friday, May 12th), at 8.45 p.m., when the President (Dr. Coulmer) will deliver his address, which will be followed by a smoking concert.

A CLINICAL meeting of the Harveian Society of London will be held on Thursday, May 18th, at 4.30 p.m., at the Paddington Infirmary, Harrow Road.

THE annual meeting of the Medical Mission Auxiliary of the Church Missionary Society was held in Queen's Hall, London, on May 3rd. Sir Leonard Rogers was in the chair, and addresses on the subject of foreign medical missionary work were given by Dr. Duncan Main (China), Dr. Emmeline Stuart (Persia), and Dr. R. B. Coleman (Egypt). The meeting was very well attended in spite of a wet evening.

DR. T. G. STYAN, on leaving Ramsgate, where he practised for 36 years, has been presented by his friends and patients with a silver tray, a cheque for £25, and an illuminated address.

WE are asked to state that an international conference on birth control will be held in London next July—11th to 14th. Friday, July 14th, will be devoted to the medical and contraceptive sections; the latter will be open only to medical practitioners and students. The fee for membership of the conference is 10s., but medical men and women can become honorary members by applying to Dr. B. Dunlop, 71, Harley Street, W.1. The Presidents of the sections are: Professor MacBride (eugenics), Professor J. M. Keynes (economics), Mr. Harold Cox (national and international aspects), the Rev. Gordon Lang (moral and religious aspects), Sir G. Archdall Reid (medical), Mr. Norman Haire (contraceptive).

THE Royal Institute of Public Health will hold its annual congress at Plymouth from May 31st to June 5th inclusive. It will be divided into four sections as follows: (1) State Medicine and Municipal Hygiene; (2) Naval, Military, and Air; (3) Bacteriology and Biochemistry; (4) Women and Public Health. The Harben lectures will be delivered by Professor T. Madsen of Copenhagen on June 1st, 2nd, and 5th, at 4.30 p.m. Lecture 1 will deal with specific and non-specific antitoxin formation, the second with antitoxic treatment of diphtheria, and the third with phagocytosis and temperature. The Mayor and Corporation will hold a reception at the Guildhall on Thursday, June 1st, at 7.30 p.m., and the National Temperance League are arranging a breakfast conference on Friday, June 2nd, at 8 a.m. The dinner of the congress will be held at the Royal Hotel on June 2nd, at 7 p.m. A series of visits and excursions have been arranged.

THE annual meeting of the American Congress of Internal Medicine and the College of Physicians was held at Rochester, Minn., in April. Changes have been made in the constitution and by-laws of the organization, which, according to the statement of Dr. Frank Smithies, secretary-general of the organization, will place the practice of internal medicine on the same ethical plane that surgery now enjoys in America through the efforts of the American College of Surgeons. A candidate for Fellowship of the American College of Physicians must be a graduate of a medical school of the first rank, a member in good standing of his local, state, or national medical societies, he a licentiate in the state wherein he resides, or engaged in practice or scientific research in a hospital or recognized institution; he must be at least 25 years of age and have received his qualifying diploma at least five years before becoming a Fellow; an applicant for membership must be engaged in teaching or research, in charge of a hospital of a hundred or more beds, or affiliated with medical or laboratory departments of the United States or Canadian army, navy, or public health services; in default of these attainments he must have submitted a clinical report on fifty patients who have been actually under his care.

A CONGRESS of mental hygiene, organized by the French League of Mental Hygiene, will be held in Paris at the Hôtel des Sociétés Savantes, 28, Rue Serpente, from June 1st to 4th. The subscription has been fixed at fr. 25 for members who take part in the discussions, and fr. 10 for associate members who take no active part in the work of the congress. The treasurer is Dr. Dupain, 1, Rue Cabanis, Paris.

WE greatly regret to announce, as we go to press, the death of Sir Henry Davy, K.B.E., C.B., consulting physician to the Royal Devon and Exeter Hospital, who was President of the British Medical Association at the Annual Meeting in 1907.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

INCOME TAX.

"M. M." inquires as to his liability as an assistant.

"(a) He is not liable to assessment in respect of the value of board and lodging received in kind. (b) "A present of £5 every Christmas" appears to be liable to assessment if it is received in consideration of services rendered—for example, if his principal is entitled to treat it as a professional expense.

"FOGGED" has a pension, and since making his income tax declaration for 1921-22 has taken up a temporary appointment with a county council, being paid according to work done.

"* Our correspondent is liable to payment of income tax on the amount of his additional earnings in the period to April 5th, 1922; it may save him some correspondence in the future if a supplementary statement is made through the Pensions Office or through the office of the local inspector of taxes, though he can probably leave the matter with the authorities on the assumption that it will be dealt with when the county council lodges its salary list with them.

"F. M. S." holds a post as medical officer to a private mental hospital, receiving a fixed salary and board and lodgings for his wife and himself.

"* Only the salary and other cash emoluments, if any, are assessable.

LETTERS, NOTES, ETC.

THE Registrar of the General Medical Council informs us that we were in error in supposing that the vacant site in Oxford Street, referred to in the paragraph headed "From Grave to Gay," on p. 491 of our issue of March 25th, was that formerly occupied by the house of the General Medical Council. The vacant space is No. 311, Oxford Street, whereas the house of the General Medical Council was 299. The correspondent who supplied us with the information was under the impression that the houses in that part of the street had been renumbered.

DR. ARBOUR STEPHENS (Swansea) asks for the opinion of readers as to whether a point half-way between the right acromion process and the left anterior superior iliac spine would be of value in correlation with the heart's impulse or apex beat. The average length in a man is, he says, about one inch longer than in a woman. Any marked deviation from the average is, Dr. Stephens thinks, significant.

VIENNA CLINICS.

DR. E. W. SCRIPTURE writes to supplement the information in his letter published on April 22nd, p. 661. He states that during the summer semester there will be over twenty courses in neurology and psychiatry in Vienna. At the Neurological Institute foreign doctors are charged 1,000 crowns for the course, with an additional laboratory tax of the same amount monthly. At the present rate of exchange this appears to be equivalent to about £100. The clinic for neurology is conducted by Professor Wagner and Inspector among the courses there is one by Dr. Strausky, position: "We are happy to pathologize (Psycho-pathology in Daily Life, in member of our the Life of Peoples)," and Dr. Schilder will give natural force unanalytic demonstrations. Our correspondent our body in all since or Freud is no longer connected with the time being devoted to private practice.

OPERATIONS FOR TONSILS AND ADENOIDS.

THE Secretary of the Belgrave Hospital for Children writes: With reference to the suggestions made by the Council of the Laryngological Section of the Royal Society of Medicine regarding the treatment of children suffering from tonsils and adenoids, a large number of children receive treatment for throat affections at this hospital, and in the past they have been treated in the out-patient department as at other hospitals. Last autumn, however, the committee of management took the first step towards improving the conditions in providing an ambulance to convey the children to their homes instead of allowing them to travel in public vehicles shortly after operation. As a further step, on May 1st a special ward of ten beds will be opened, reserved entirely for the admission of throat cases; the children will be admitted the day before operation, and will stay in hospital three days and three nights, or longer if necessary.

EXPECTANT TREATMENT OF MEASLES AND INFLUENZA.

DR. THOS. CARRUTHERS (Kilbarrack, Renfrewshire) writes: An epidemic of measles has reminded me of a formula I used in former epidemics: "Drinks of water till they ask for something to eat, and don't let them—up?—out till the cough's away." I am also reminded of my formula in the recent influenza epidemics: "Keep your bed till the cough's away and the appetite's back." It is many years ago now since I learned I had earned the title of "the cold water doctor," on account of my treatment of the early stage of any fever, apparently to distinguish me from the "milk and soda" and "plenty of sloppy food" doctors all round about! When will we learn to break away from the tradition of the textbooks and the fever hospitals, just as we are only now breaking away from the tradition of the maternity hospitals of the two-hourly feeding of infants?—a thing I broke away from ten or more years ago upon discovering that the seeds were naturally from five to seven in the twenty-four hours with different babies. There is far too much theory and worship of authority in the practice of medicine and too little observation of fact for oneself.

AESCULAPIUS AND CONSUMPTION.

DR. R. J. S. McDOWALL (Leeds) writes: One cannot help thinking that the interpretation put by Mr. Morley Roberts on the of Aesculapius to consumptives requires further consideration. The date season in Egypt only lasts a few weeks, and in which dates grow in greatest profusion is most consumptives—namely, the delta where the air is humid, and relaxing in summer, cold and rare suitability of the Cairo district for consumption grave doubt. Assouan, in Upper Egypt, well suited during the winter months, a hundred miles farther south few patients fresh dates are certainly not available. Those who have sojourned in the country will have noticed these points. Does not the value of the date lie in its having a high vitamin content and a large amount of sugar in a form easily assimilated?

BARLEY WATER.

Mrs. J. P. O'HEA, F.R.C.S. Eng., M.B. Lond. (Chichester), writes: Barley water is commonly advised as a diluent of cow's milk for infant feeding, and pearl barley is used also in the preparation of food for invalids. Barley as such is a very digestible and nutritious cereal; but I believe that pearl barley is only too often manufactured by the bleaching action of sulphur, and this is a process not calculated to render it more digestible—rather the reverse. The point is of considerable importance considering the feeble digestive powers of the infant, and also the fact that barley water is commonly prescribed when the digestive powers are enfeebled in such conditions as dyspepsia and "summer diarrhoea."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 28, 29, 32, 33, and 35 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30, 31, and 32.

THE appointments of certifying factory surgeons at Cerrig-y-Druidion (Denbigh), Cobham (Surrey), Gnosall (Stafford), and Knutsford (Chester), are vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 427, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive postage letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

451. The Effect of Mercury in Syphilis.

HELLER (*Klinische Wochenschrift*, March 11th, 1922) brings forward statistical evidence against the recent views: (1) That mercury is only a symptomatic remedy and does not influence the course of syphilis and at the best leads to a symptomatic cure, whilst salvarsan alone can produce a true cure; (2) that all cures of syphilis before the salvarsan period are instances of spontaneous recovery. In countries where antisyphilitic treatment is lacking a large proportion of tertiary syphilitic cases occur; in no country does spontaneous cure occur, so that tertiary symptoms fail to develop. The statistics of Glück in Bosnia show the high percentage of tertiary syphilitic cases in some districts and their great reduction under the influence of mercury given in the early stages of syphilis. Women suffer much more frequently than men from severe syphilitic lesions. In women primary symptoms are often overlooked and mercurial treatment neglected. Syphilis is much more common amongst men. If we allow that the number of syphilitic men is three times as great as the number of syphilitic women, and that women are treated with mercury much less frequently than men, then if mercury has no influence on the course of the disease, especially in preventing severe syphilitic lesions of internal organs, the percentage of syphilitic lesions found *post mortem* amongst men should be three times as great as amongst women. But if mercurial treatment in men has an influence, the percentage of severe lesions found amongst men will be less than three times the percentage amongst women. This difference in percentage would be less the more women were affected by syphilis, and the more frequently they were treated with mercury. Hence the difference would be greater in earlier than in recent times. Heller's collected *post-mortem* statistics show that syphilitic lesions which are influenced by mercury were found much less frequently amongst men than amongst women. In 1881-83 the lesions just named were found amongst women five times as frequently as amongst men (or fifteen times if we allow for the less frequency of syphilis amongst women). In 1911-13 the figures were 2.5 and 7.5 respectively. Heller concludes that mercury is not only a symptomatic remedy, but that it favourably influences the course of syphilis. So long as it has not yet been proved that salvarsan or other remedies do the same or more (and this can only be proved by pathological anatomy in the next twenty years) the medical man is not justified in discontinuing the use of mercury.

452. Whooping-cough in the Newborn.

MILIO (*La Pediatria*, April 1st, 1922) reports two cases of whooping-cough occurring in infants aged 8 and 10 days respectively. In both cases infection occurred through other children in the house. In the first case the child started sneezing, coughing, etc., on the sixth day, and later the characteristic paroxysms appeared. From the twelfth day onwards the temperature of 1.2 c.c.m. of ether were given each day. After the third injection the number of coughing fits was lessened, and after the sixth injection the attacks were much less severe and the child was able to sleep three or four hours at a time. No further injections were given, and the child steadily improved. In the second case the symptoms first appeared on the seventh day, and on the thirteenth other injections were commenced. After the eighth injection the condition was so much improved that treatment was discontinued. Whooping-cough at so early an age is uncommon and often fatal. The author believes the ether injection treatment completely justified itself by the results obtained.

453. Endocrine Disorder and Mental Disease.

LEWIS and DAVIES (*Journ. Nerv. and Mental Dis.*, November and December, 1921, and January, 1922) record the results of a correlative study of endocrine "imbalance" and mental disease with a view to determining the relationship between physical manifestations, blood chemistry, and the mental syndrome. Twenty-two cases showing definite endocrine disorders were selected, without reference to their mental type; their sugar tolerance and thyroid function were tested, and the urine examined for uric acid, urea nitrogen, and creatinine. Twelve of these suffered from hypothyroidism, and the sugar tolerance was increased in each; as also in two cases of hypoadrenia, one case of hypopituitarism, and in one poly-

glandular type. This points to the value of the test in analysing these cases and in indicating the value of x-ray treatment on hyperthyroidism. Regardless of the main type of lowered function, a preliminary administration of thyroid gland enhances the action of the pituitary, suprarenal, or other glands to be given later. The thyroid function test is contraindicated in pronounced Graves's disease, manic and anxiety conditions with rapid heart and excitability, and in advanced valvular heart disease. Thyroid extract given in hypoglandular types, by accelerating the organism generally, renders introversion more difficult and aids psychotherapy, the changes in behaviour and improvement in many cases commencing simultaneously with the thyroid testing. In the author's view, both the sugar tolerance test and the thyroid function test are extremely valuable in differentiating and estimating those hypo- and hyper-glandular types which present but slight signs.

454. Hypodermiasis.

This disease is caused by the entrance into the subcutaneous tissues of the larvae of one of the species of fly of the genus *Hypodermia*, the larvae invading the body either by burrowing directly into the skin or by being taken into the mouth, thereby causing the common disease of cattle known as ox warble. Human beings may also be attacked in a similar way, and NOXON TOOMEY (*Brit. Journ. of Derm. and Syph.*, February, 1922) gives the following description of the clinical pathology of such cases. After the heel-fly has laid its eggs on the human skin or undergarments the hatched larva quickly burrows its way into the skin. The arrival of the larva in the subcutaneous tissues causes a local subacute cellulitis round the point where the larvae are embedded, usually noticed in December or January. The larvae migrate in the subcutaneous tissues and along the fascial planes and cause fresh areas of inflammation wherever they settle down. The track of the larva to its new resting place can often be made out, being seen as a faint irregular diffuse line connecting the old area of cellulitis with the newer inflamed area. When the mature larva is ready to leave the body (warble stage) a tender nodule appears below the epidermis and in the corium, around which the skin is oedematous or erythematous. After about ten days a small black point appears on the apex of the inflamed area, over which the epidermis breaks down, resulting in the escape of sero-sanguineous discharge. Through this hole the larva projects its air-breathing apparatus. From thence onwards the larva grows rapidly until it attains about 3 cm. in length. In the meantime the discharge from the warble becomes purulent, and in this stage the inflamed area is indistinguishable from an indolent pyogenic furuncle except for the central canal and the sensation of ballottement felt on palpation. Finally, the mature larva emerges from the warble, usually in the early morning, and, falling to the ground, its colour changes to black and it is converted into a pupa, whence in three or four weeks the fly emerges. In the later stages of the disease, if the aperture of the warble is incised the larva may be extracted with dressing forceps; whereas in the early stages, when the larva is still migrating, Toomey recommends that the surgeon should cut down on the larva, a procedure which may result in a protracted search. The heel-fies do not oviposit on a person whose body and clothing are free from animal odours, so that personal cleanliness is the best means of preventing hypodermiasis in man. Ox warble disease is a great source of suffering to cattle, and results in much damage to hides.

455. Typhoid Fever in Children.

UGOY (*Rev. med. del Uruguay*, January, 1922) states that during the first half of 1921, 176 patients, aged from 5 to 14 years, were admitted to Professor Morquio's clinic at Montevideo; 81 were boys and 95 girls; 27 were mild, 108 moderate, and 41 severe cases. The mortality was 7.38 per cent. With the exception of a few cases admitted to hospital supposed to be suffering from appendicitis, pneumonia, or meningitis, all the cases presented the characteristic clinical picture of typhoid fever. Only 33 cases had diarrhoea, which was probably due to administration of purgatives before admission. Enlargement of the spleen, on palpation, was found in only 31. Rose spots were seen in all but 32 cases, in which, however, they may have been present before admission. Blood cultures were made in 96 cases and positive results were obtained in 52. The negative results could be explained either by the fact that many patients were admitted late in the disease

or by the difficulty in obtaining sufficient blood from the child for a blood culture. Vidal's reaction, which was performed in 139 cases, was positive in 119 and negative in 20. Three cases had a relapse. The epidemic presented the following clinical peculiarities: (1) Frequency of pyogenic complications in the skin, cellular tissue, glands, and bones. The typhoid bacillus was found in some cases, and in others the ordinary pyogenic organisms. Suppurative otitis was observed in 8 cases. (2) Frequency of haemorrhages in the skin and from the mucous membranes. Seven patients had intestinal haemorrhage. (3) Frequency of generalized desquamation resembling that of scarlet fever. As regards complications, two had intestinal perforation which ended fatally, one had myocarditis which ended in recovery, one had phlebitis, and a certain number had cerebral or meningeal involvement. No specific vaccine was employed, as Morquio had observed that vaccine treatment did not shorten the disease or render it milder in the child.

456. Ammonium Carbonate in Erythema Nodosum.

AMMANN (*Schweiz. med. Woch.*, March 9th, 1922) has obtained remarkably good results from the use of ammonium carbonate in erythema nodosum; he gives a teaspoonful of a 5 in 100 solution of the salt in a quarter of a tumblerful of water every two hours. The fever subsides, the patient experiences great relief from the feeling of illness, appetite increases, pains promptly disappear, and no fresh nodes are seen. With all this there is a corresponding considerable shortening of the course of the affection. The same salt appears to act very favourably in erysipelas. Ammann accepts Unna's teaching that it acts by increasing the alkalinity of the blood.

457. The Coexistence of Syphilis and Tuberculosis in Lymph Glands.

FREI and SPITZER (*Klinische Wochenschrift*, January 1st, 1922) state that long before the discovery of the *Spirochaeta pallida* the coexistence of syphilis and tuberculosis had been observed in a number of cases. The grounds for such a diagnosis in the absence of histological examination were a focal reaction to tuberculin, the presence of tubercle bacilli, and a positive result from animal inoculation indicating tuberculosis, and the undoubted but incomplete success of specific treatment (mercury and potassium iodide) indicating syphilis. The present writers report three cases in which the enlarged glands (cervical, epitrochlear, and inguinal) showed the *Spirochaeta pallida* as well as tuberculous infection which was proved by inoculation of guinea-pigs. A control inoculation of guinea-pigs with the puncture fluid derived from the enlarged glands containing *Spirochaeta pallida* of eight syphilitic subjects was negative as regards tuberculosis.

458. Arsenical Treatment of General Paralysis.

AUBRY and TRAMPOL (*Rev. Méd. de l'Est*, March 1st, 1922) report 27 cases of general paralysis treated with intramuscular injections of novarsenobenzol, starting with 0.15 gram up to 1.05 gram, at intervals of four days; and afterwards every eight days—the total amount given being 7 to 8 grams. The results were: 13 failures, 7 remissions with progressive symptoms later, and 7 marked remissions lasting for a considerable period—in one case nearly four years and in another two years. The improvement when it occurred was chiefly noticeable in the mental condition. No bad results were recorded. Even allowing for mistaken diagnosis and the spontaneous remissions which sometimes occur in general paralysis without treatment, the authors consider novarsenobenzol injections of much benefit in some cases. Other physicians have recorded similar results from this treatment.

459. Quinidine and Digitalis in Arrhythmia Perpetua.

KAPFF (*Deut. med. Woch.*, April 7th, 1922) has collected 299 cases of heart disease, including 19 of his own, in which quinidine was given for arrhythmia perpetua. He finds that in 156, or 52.5 per cent., the drug proved effective in restoring the normal rhythm of the heart beat. At present no conclusions can be drawn as to which morbid conditions will react satisfactorily to quinidine; all that can be said is that about every other case of arrhythmia perpetua will benefit from quinidine. As it weakens the heart, it should be given only when compensation is complete; if the action of the heart is very weak a course of digitalis should be given before the quinidine. Between two courses of quinidine there should be an interval of at least three weeks, as the patient may be particularly susceptible to this drug for some time after the completion of a first course; this interval may well be utilized to steady the heart with digitalis. The author discusses at considerable length the interaction of digitalis and quinidine, and finds it not advisable to give them simultaneously in appreciable quantities.

SURGERY.

460. Perforated Ulcers of the Duodenum.

IN this most dramatic of abdominal cases operation within twelve hours, with simple closure of the perforation, will bring about recovery in the majority of cases. BRENNER (*Surg., Gyn., and Obstet.*, March, 1922) reports fifteen consecutive cases and discusses the future welfare of the patient, the main questions being, Is the ulcer healed by simple closure, will it stay healed, and will the patient remain free from symptoms? He remarks that after gastro-enterostomy a revolution takes place in the physiology of digestion. The jejunum is called upon to assume the duodenal function, for which it is physiologically unsuited. That many thrive after this merely accentuates the remarkable adaptability of the human body. Gastro-enterostomy is a satisfactory procedure for obstruction of the pylorus in the majority of cases. He divides ulcers into two types—namely, the soft type (the more common) and the "calloused" type. He believes that simple closure by inversion will cure the vast majority of the first group; the latter require a gastro-enterostomy. With regard to a primary gastro-enterostomy, the real dangers are a 2 to 3 per cent. chance of a gastro-jejunal ulcer and late secondary sequelae which occur in some cases. Simple closure should be carried out unless the pathology demands a primary gastro-enterostomy. When in doubt do not do it. This can be done later if necessary. Late results show that of seven patients with the soft type of ulcer in whom simple closure was performed, all are well and symptomless; of two with the hard type of ulcer in whom secondary gastro-enterostomy was performed one remains well, the other complains of dragging pain. In two cases examined at a later date the duodenum appeared absolutely normal and the ulcer site had completely disappeared. In conclusion the writer agrees that to state dogmatically that all cases treated by simple closure will result in permanent cure is as illogical as to insist upon a primary gastro-enterostomy as a universal procedure.

461. X-Ray Treatment of Throat Infections.

WITHERBEE (*New York Med. Journ.*, March 1st, 1922) considers that the treatment of focal infection of the throat by x rays, as compared with surgical removal of tonsils and adenoids, gives more thorough and complete results, besides being safer and applicable to cases in which there may be contra-indication to operation. With the patient lying face downward and the head turned to the side, the position and angle of the patient and tube corresponding to that for radiographing the lower molars, about eight treatments to both sides, at two-weekly intervals, are given, using a 7-inch spark gap, five milliamperes, four minutes time, 10-inch distance, and 3 mm. of aluminium as filter. By this method the shrinkage of the tonsil and lymph tissue of the lateral and posterior walls of the throat produces a drainage of the crypts of the entire mucous membrane, and in 80 per cent. of diphtheria carriers so treated bacilli were removed in from two to four days. From an experience of nearly 500 cases so treated, Witherbee is of opinion that the method is free from serious complications, burns and injury to adjacent glands being impossible under proper technique. The shrinkage following treatment revealed two cases of abscess of the tonsil completely encapsuled by fibrous tissue. The method is specially indicated in chronically infected throats in vocalists, and in those cases associated with rheumatism.

462. Pancreatic Cyst Treated by Enucleation.

MATHIEU (*Bull. et Mém. de la Soc. de Chir. de Paris*, March 21st, 1922) reminds us that the majority of pancreatic cysts have been regarded as pseudo-cysts without an epithelial lining, due to the accumulation of pancreatic juice and blood following on a process of auto-digestion localized in the pancreas. Rarely, however, true cysts may be found where there is an epithelial lining on their inner surface. The origin of these true cysts is often difficult to make out, and he reports a case where the lining of the cyst had cells similar to those of the canal of Wirsung. The patient was 58 years of age and had suffered from abdominal symptoms for twenty-three years following on a kick in the abdomen. There were frequent attacks of severe abdominal pain and digestive disturbances resembling an organic lesion of the pylorus. The patient had also lost a considerable amount of weight. The shape, position, and relative fixity of the tumour and its freedom from the liver, and the results of x-ray examination, enabled a correct diagnosis to be made. At the operation an incision was made on the right side of the abdomen to reach the cyst. The enucleation of the tumour was very difficult, requiring a dissection of the bile duct and portal vein adjacent to the cyst. The after-results were satisfactory—the digestive troubles disappeared and

the patient put on weight. An examination of the tumour after removal showed it to be a multilocular cyst with walls having a structure like those of the canal of Wirsung. The rarity of cysts of the pancreas which can be removed by enucleation makes this case of interest.

453. Bilateral Cystic Kidney.

ROLANDO (*Journ. d'Urol.*, February, 1922), who records six cases in patients aged from 33 to 57, states that three theories have been advanced to explain the pathogeny of polycystic kidney—namely, (1) the inflammatory theory of Virchow, according to whom the renal cysts are due to a chronic inflammation followed by peritubular sclerosis and dilatation of the tubules; (2) the theory of an adenomatous tumour, based on the structure of the cysts, in which endocystic papillary formations and epithelial masses are often found; and (3) the theory of congenital malformation which Rolando himself is inclined to adopt. Almost all his patients had a more or less cachectic complexion, loss of appetite, dyspepsia, constipation, a slow but progressive loss of strength, and, more rarely, a sensation of dead fingers and oedema of the ankles. Although Pousson declares that polyuria and albuminuria are almost constant in bilateral cystic kidney, Rolando found that the urine was often normal in quantity, specific gravity, colour, reaction, and amount of urea; albumin was almost always absent at first, and it was only at an advanced stage that a slight trace was found. As a rule Rolando did not detect any appreciable difference in the specimens of urine collected separately from the two kidneys, either as regards the amount of urea or the microscopical examination of the sediment. As the destructive process usually develops simultaneously and in the same degree on both sides, there is no marked compensatory hypertrophy on one side. Haematuria was noticed in three of the six cases, being slight in two and considerable in one. In none of them was it accompanied with pain or renal colic. Although Pousson states that the development of polycystic kidney is accompanied in half the cases by lumbar pain, this symptom was noticed in only one of Rolando's cases. A renal tumour is the chief diagnostic sign. Pousson gives the following statistics of its frequency. Among 157 cases which did not come to operation no tumour was noted in 63, in 25 it was unilateral, in 44 bilateral, and in 20 an abdominal tumour was noted; among 167 in which an operation was performed the tumour was bilateral in 21, unilateral in 104, and in 42 no tumour was found. The polycystic kidney on increasing in size may give rise to symptoms of occlusion or compression of the ascending or descending colon. Glaser has recorded a case of death from septic angiocholitis due to pressure on the common bile duct by the right polycystic kidney. As regards the prognosis, apart from complications a polycystic kidney is compatible with a long life. Owing to the unfavourable results following nephrectomy, Rolando considers it advisable to refrain from any operation, especially in advanced cases, except in the case of suppuration of the polycystic kidney, which must be treated like any other case of renal suppuration.

454. Influenza Simulating Appendicitis.

DEBS (*Schweiz. med. Woch.*, April 13th, 1922) points out that during the last wave of influenza there have been several cases in which the symptoms at the onset of the disease suggested peritonitis with perforation of some abdominal viscera. He notes as remarkable the fact that he saw no such cases during the epidemics of 1918 and 1919, whereas of late they have been frequent. With regard to the differential diagnosis of genuine appendicitis and influenza complicated by severe diaphragmatic pleurisy or inflammation of the nerves of the abdominal wall, he points out that appendicitis never begins suddenly, and that a temperature over 39.2° C. at the onset of the disease in children is certainly not characteristic of appendicitis. The general appearance of the patient is instructive: in acute appendicitis the patient never looks feverish or shows conjunctival injection. A sudden onset with shivering and rigors is indicative of influenza rather than acute appendicitis, but the blood count is of little value in the differential diagnosis, as the leucopenia of influenza is a very uncertain phenomenon.

455. Erect Dislocation of the Humerus.

PRINGLE (*Glasgow Med. Journ.*, March, 1922) records an instance of this condition, which appears to be an injury of great rarity. The patient had fallen across the well of a hoist and remained suspended over the well with his right arm held in extreme abduction and elevation by the weight of his body until rescued. A typical "laxatio erecta" resulted. The arm was abducted to an angle of 35 degrees, the head of the humerus caused a bulging of the right axilla, and the axillary artery lay over it. Reduction was effected quite easily by traction and adduction of the limb. X-ray examina-

tion showed no fracture, and no nerve disturbance beyond "pins-and-needles" in one finger was detected. The scapulo-humeral muscles seemed responsible for holding the limb in the elevated position, the pectoralis major being quite slack. The teres major and latissimus dorsi may also have something to do with maintaining the erect position if the head of the humerus passes dorsal to the teres major; the head would then be directed towards the posterior axilla, and not forwards as in this case. In reduction, traction on the limb brings the head of the bone away from the thoracic wall and allows it to pivot into the glenoid cavity between the muscles of the tuberosities as soon as adduction follows. There is a variety of horizontal or right-angled dislocation where the abduction of the arm is not so extreme as this. It is intermediate between the subglenoid and erect types, and is also rare. An example of this variety is also described by the writer. In both cases the movements at the shoulder-joint were rapidly and perfectly recovered, so that any extensive injury to muscle was doubtful.

OBSTETRICS AND GYNAECOLOGY.

456. Obstetric Uses of Pituitary Extract.

CROX (*Amer. Journ. of Obstet. and Gynec.*, March, 1922) records the use in 150 cases of pituitary extract, given in doses of 3 minims to 1 c.cm., injected into the skeletal muscle or (in cases of Caesarean operation or severe post-partum haemorrhage) directly into the uterine muscle. In 69 per cent. of 45 cases it was possible, at dates ranging from the eighth month of pregnancy to the third week of post-maturity, to induce labour by oral administration of 2 ounces of castor oil, followed two hours later by 10 grains of quinine sulphate, repeated once or twice; with the last dose of quinine 5 minims of pituitary extract were injected intramuscularly, and two hours later a second dose of pituitary extract was given, which occasionally was again repeated. The results obtained by combining the three drugs were much better than those obtained by giving them separately or in combinations of two. The induction of labour by this method is believed to have prevented intra-partum infection after premature rupture of the membranes. In the first stage of labour pituitary extract was given only in six cases of primary uterine inertia, five of which responded to the treatment. Apart from primary inertia, the use of pituitary extract at this stage is most dangerous; of the six cases mentioned, in three the uterine contractions became continuous, the foetal circulation was embarrassed, and it became necessary to terminate the labour under deep anaesthesia by podalic version or forceps extraction. It is concluded that even for primary inertia pituitary extract should be given in minimal doses and with the utmost caution. Another possible indication for its use in the first stage is found in cases of marginal or partial placenta praevia, with incomplete cervical dilatation and rupture of the membranes. In the second stage of labour, pituitary extract may sometimes be given with advantage for secondary uterine inertia; it is necessary, however, carefully to observe the condition of the foetal heart, for the resultant strong uterine contractions may impede the foetal circulation and even produce direct compression of the foetus. After administration of pituitary extract, foetal meconial and cerebral haemorrhages have been found in certain cases at autopsy, and even in the second stage of labour a conservative attitude is requisite with regard to this treatment. After injection of 1 c.cm. intramuscularly immediately after birth of the child, the writer finds that the third stage of labour may be most favourably influenced: it is of shorter duration (average 12.1 minutes), and is accompanied by a smaller loss of blood (225 c.cm. compared with 500 to 500 c.cm. in control cases). Hour-glass contraction was not observed by the author.

457. Tubal Carcinoma.

ACCORDING TO STANCA (*Zentralbl. f. Gynäk.*, April 1st, 1922) about 150 cases of carcinoma of the Fallopian tube have been recorded since the first description of this condition thirty years ago. Primary tubal carcinoma originates in the papillae of the mucosa, and in the majority of cases affects one tube only; the diffuse form, which not infrequently is associated with sacculi, leads to formation of large soft tumours resembling inflammatory tubal swellings, but in the circumscribed form the tumour is as a rule small. Secondary carcinoma is more frequent, and is found in diffuse or circumscribed forms in association with uterine or ovarian carcinoma; in the great majority of cases the tubes of both sides are affected. Inflammatory adnexal conditions usually accompany tubal carcinoma, but it is uncertain whether the inflammatory or the malignant condition comes first. Clinically, tubal carcinoma is difficult of diagnosis; suspicious factors are the age of the patient (usually from 40 to 50), the

repeated occurrence of colicky pains of gradually increasing and then gradually decreasing intensity, the appearance of a haemorrhagic or purulent discharge after these pains have been experienced, and a rapid increase in size of the tumour, together with speedy deterioration of the patient's general condition. Formation of metastases is widespread and early.

468. Salpingotomy for Tubal Gestation.

WHITEHOUSE (*Journ. of Obstet. and Gynaecol. of the British Empire*, 1922, 29, 1) believes that salpingotomy is worthy of trial in the treatment of tubal mole and tubal abortion. Three patients with tubal mole, one with partial tubal abortion, and one with fulminating rupture were treated by salpingotomy, the mole being excised after incision of the tube, and haemostasis and repair being effected by catgut sutures. In each case recovery was normal. Salpingectomy is probably preferable for tubal rupture, in cases of which there is serious risk from haemorrhage and extensive tubal lacerations occur. From dissections of thirty fresh specimens of tubal mole, abortion and rupture, Wilson and Whitehouse found that tubal mole is the direct result of intratubal rupture and that the mole retains a narrow basis of attachment to the tubal wall, usually situated on the floor of the tube and always at the proximal end of the mole; that the surface of the pedicle of the mole usually shows traces of tubal mucosa; and that macroscopic or microscopic evidence of pre-existing inflammation of the tubal walls is exceptional in the case of mole and abortion. In a series of ten cases after salpingotomy and extraction of the ovum the tube was excised and submitted to microscopic examination: signs of inflammatory change were absent, and Whitehouse believes the abnormal implantation of the gestation to be purely accidental.

469. Pregnancy after Nephrectomy.

ACCORDING to MATTHEWS (*Amer. Journ. of Obstet. and Gynec.*, March, 1922) pregnancy in a woman from whom one kidney has been removed is little more hazardous than in normal women, providing the remaining kidney is functioning properly. Albuminuria may occur as in normal subjects during the later months of gestation, but responds to treatment as well as that of subjects having two kidneys. Marriage and pregnancy after nephrectomy are permissible if tests have shown the remaining kidney to function normally for a year or more, or for three years or more in cases in which the nephrectomy was performed for unilateral renal tuberculosis. In 241 cases of nephrectomy taken from the literature or studied personally the writer found 265 pregnancies, with 250 normal labours and only 2 deaths; 60 per cent. of the patients showed more or less albuminuria during the later months of pregnancy. These patients tolerate morphine well, and may be subjected to other forms of anaesthesia than that by chloroform; chloral hydrate and veronal are borne badly by them.

470. A Rare Cause of Atresia of the Vagina.

HOLZAPFEL (*Deut. med. Woch.*, April 17th, 1922) records the case of a well-developed girl of 13 who had not yet menstruated. At 9 years of age she had suffered from a severe attack of measles. Eight months before being seen she suffered from strangury, and two months before it was noticed that the abdomen was distended. For some time she had complained of headache, but there was no fever or other symptom. On examination the distended abdomen was found to contain a swelling, which extended 3 cm. above the umbilicus, and was rather nodular above, but elsewhere smooth. The pale red hymen was closed, but was hardly at all distended. In the absence of local symptoms, retention of menstrual products seemed unlikely, and in spite of the closed hymen pregnancy was suspected; a tumour of one ovary was another possibility. Pregnancy being excluded after a considerable observation period, laparotomy was performed, and the tumour found to consist of the uterus perched on top of a large collection of fluid in the vagina and cervix. The abdominal wound was therefore closed, and by perforation of the hymen, pure pus, containing streptococci, was evacuated. Uneventful recovery followed. The atresia was probably provoked by an inflammatory reaction during the attack of measles.

PATHOLOGY.

The Schick Reaction.

471. THE intradermal reaction to diphtheria toxin has been tested by VINCENT, PILOD, and ZOELLER (*C. R. Soc. Biologie*, March 11th, 1922) on a group of 2,816 men of 20 to 22 years of age. A positive result was obtained in 1,344 cases and a negative in 1,472. They divide their positive cases into those giving

a marked reaction and those giving a feeble one; amongst the former diphtheria occurred to the extent of 3.29 per cent., while amongst the latter only to 1.94 per cent. Comparing the number of cases of diphtheria arising in those with a positive Schick with those giving a negative one they find that there was an incidence of 2.68 per cent. amongst the former and one of 0.27 amongst the latter. This is rather in discord with the reports of other writers, who usually attribute an almost complete immunity to those giving a negative reaction. In view of this discrepancy one is bound to consider the question of an error in the technique, for it has been shown that numerous sources of fallacy—particularly in connexion with the fragility of the toxin—are liable to creep in, and thus mar the readings of the test. At the conclusion of their article the authors put a question of considerable interest—namely, if a common angina (due, for example, to the staphylococcus) occurs in a patient who is a carrier of the Klebs-Loeffler bacillus, and this bacillus is obtained in culture from his throat during the attack, is he to be considered as suffering from diphtheria or not?

472.

Cancer Mortality.

ROUSSY and LEROUX (*Bull. de l'Assoc. française pour l'étude du Cancer*, February, 1922) performed 400 autopsies on old people dying from various causes, and amongst these found 34 cases of malignant disease, of which 33 were carcinomata and 1 a sarcoma. In 12 cases metastases were present—7 in the liver, 6 in the glands, 2 in the lungs, and 1 in the peritoneum. In 11 cases death was attributable to progressive cachexia, in 3 cachexia plus secondary infection, whereas in 20 cases death was due to some completely unrelated disease. Of these 34 cases, 21 had been diagnosed by clinical examination, 10 were discovered at autopsy, and 3 by microscopic examination only. It is commonly said that the frequency of cancer increases with the advance of years, but in this series of 400 deaths only 34 times was noted, and in 13 of these cases the after death. In the ordinary method these 13 cases would not have appeared as cancer. A further analysis of these figures reveals the interesting fact that whereas in the adult cancer is the direct cause of death in the majority of cases, in old people, on the contrary, in two-thirds of the cases death is due to intercurrent diseases totally unconnected with cancer, and under these conditions the aged die with the same symptoms as those unaffected with malignant disease.

473.

Living Sensitized Cholera Vaccine.

WHAT is the most efficacious vaccine for prophylactic use in cholera? Haffkine's original vaccine consisted of living bacilli, attenuated for the first dose, and made more virulent for the second. But the injection of living organisms into the body is open to the objection that they may be excreted into the intestinal tract—as has been shown by Besredka for the typhoid bacillus—and thus render the patient a carrier of the organism. According to MASAKI (*Ann. Institut Pasteur*, March, 1922) this can be avoided by the use of cholera bacilli sensitized with immune serum. Working with guinea-pigs he finds that if the organisms be submitted to the action of the serum for a certain length of time all danger of their being transported in the living state to the blood and tissues of the body is avoided, for they appear to be taken up by the phagocytes—if given by the intraperitoneal or subcutaneous routes—before any generalization can occur. Further, by altering the time and the temperature of the process of sensitization he is able to produce vaccines which can be given in small or in large doses, which will produce a rapid or a slow immunity, and which will exert a protective effect for at least three to five months. His conclusion that sensitized living bacilli are the most favourable material for vaccine purposes deserves to be modified by the fact that he completely omits to mention whether his experiments have been extended to human beings.

475. The Colloid Benzoin Reaction in the Cerebro-spinal Fluid.

FERRARO (*Il Policlinico*, Sez. Prat., January 16th, 1922) employed the colloid benzoin reaction introduced by Guillain, Laroche, and Lecchello in 16 individuals with a normal nervous system and 50 patients suffering from various nervous disorders with the following results: (1) The reaction was negative in the normal cerebro-spinal fluid. (2) In all cases of general paralysis the reaction was markedly positive. (3) In some definitely syphilitic diseases of the nervous system the reaction was negative. (4) In five cases in which the syphilitic origin of the affection could be excluded on clinical and serological grounds the reaction was positive.

THE BEST TIME TO SELL A CAR

THE question of selling a second-hand car and buying a new one is a question that is always before the medical profession, and some information that will help to solve the problem will no doubt prove welcome. "I would have a new car every year if only I could sell my old one," is a remark often heard, and a thought that is ever present amongst motorists, and there is little doubt but what such a policy, if it could be put into practice, would be the wisest and most economical in the end. The difficulty of finding a purchaser of a second-hand car depends upon the number of potential buyers who know it is for sale. Advertising in the second-hand car columns is sometimes productive of satisfactory results. Sending a car to auction or to a garage for sale or parting with it as part payment for a new one usually results in one wishing that something different had been done. The best time to sell a car is whilst it is being used and in good running order. This, however, is seldom possible, but it appears a solution to the problem has been found at last.

A NEW IDEA

An innovation in the form of a second-hand car sales registry demands attention and by the service it renders deserves success. The name given to this concern is the MOTOR SALES REGISTRY, who for an annual subscription of one guinea keep all its members regularly posted with the names and addresses of possible buyers of their cars. The real service underlying this idea is obvious. Occasionally you meet someone who makes you a good offer for your car. Whether you accept or not you are naturally pleased with the opportunity to sell. You know that if you accept you can order a new car with the comfortable assurance that you are to have no worry or unexpected loss in connection with the sale of the old one. Briefly, this explains the service of the Motor Sales Registry, who provide you with opportunities to sell if you wish, by finding prospective buyers for your car at your price whilst you are still using it. This means full service from your car and minimum depreciation when you sell it. Instead of a chance meeting with an acceptable offer, they make it their business to locate and keep you furnished with the names of prospective purchasers interested in just such a car as yours. They do not wait for you to apply to them, but keep you regularly posted with names and addresses of people within easy reach who wish to buy a similar car to yours. Whether you communicate with these people or not depends upon your inclination to sell. Your name and address is not disclosed to the possible purchaser, that is left to you to do if you wish to sell.

THE OBVIOUS ADVANTAGES

of such a service for a small annual subscription will no doubt appeal to the members of the medical profession as a good investment. The service applies to any car registered for sale, and does not finish when the car is sold, but continues just the same for the next car, until the expiration of one year from the date of the subscription. A commission of 2½ per cent. only is charged when the car is sold through the medium of the Registry. The personnel of the Motor Sales Registry includes men who have directed the sales of many motor manufacturers since the earliest days of the industry, which augurs well for the service it will render to subscribers. Full particulars and registration forms may be obtained post free from the Motor Sales Registry, Ltd., 11, Warwick Row, Coventry.

THE ORIGINAL.

The Ideal All-Weather Food-Drink.

— Made in England. —

Horlick's Malted Milk is meat and drink in one, because it contains all necessary nutritive elements in the correct proportions demanded by Nature to support life and maintain health. Composed of the extracts of selected malted barley and wheat flour, combined with pure, Pasteurised cow's milk, it is perfectly digestible and rapidly assimilated, while Vitamines, those growth-promoting essentials, are supplied by both the milk and the grain.

Ready in a moment by stirring briskly in hot or cold water only.

To secure the original, specify Horlick's when prescribing

Samples will be forwarded free and postage prepaid to
Members of the Medical Profession on application to

HORLICK'S MALTED MILK CO., SLOUGH, BUCKS, ENGLAND.

Opium . . .

should always be prescribed in the form of

NEPENTHE

A preparation derived *entirely from Opium* by a process which, whilst eliminating those constituents that give rise to disagreeable after effects, retain in the fullest degree the unrivalled sleep-producing and pain-allaying properties of the drug.

Preparations which make various claims to unique merit are continually being offered to the profession: they often prove exaggerated and ephemeral.

The reputation of **Nepenthe** is based not on our advertisements but on the experience of thousands of practitioners of successive generations.

Nepenthe is sent out in 2 oz., 4 oz., 8 oz., and 16 oz. bottles.

Dose: Five to Forty Minims.

SOLE MAKERS AND PROPRIETORS:

FERRIS & CO. Ltd. Wholesale and Export Druggists, **BRISTOL.**

N.B.—Nepenthe is protected by registration.

THE MALTINE COMPANY'S NEW SPECIALITY.

Maltine

TRADE MARK

A combination of "Maltine," Olive Oil and Glycerophosphates in palatable *powder form*. Nourishing and nerve stimulating. For building up the weak and debilitated. Aids assimilation and improves nutrition

Trial bottle gratis on receipt of professional card.

THE MALTINE CO., Ltd., 9 (B.M.), Holborn Viaduct, London, E.C. 1.

The "A.B.C." of DIET.
Because it is *very rich in the Vitamins*
'A.' 'B.' & 'C.' there is no tonic
food more serviceable in
wasting diseases.

'ROBOLEINE'

*Delicate
children say
there is no tonic food
that they find so palatable.*

"It is a fatal error to expect the milk of a foreign species to be immediately adapted to and utilized by the human infant; the differences between that of the woman and that of a lower animal would indicate, even when given to the newly born with normal functions, that we must wait until the delicate digestive and assimilative organs can make use of the material designed for a more vigorous animal."

—A Member of the English Speaking Conference on Infant Mortality.

It follows that until such time as the digestion is developed the best food is that which approximates most closely in its composition to the maternal milk.

A Post-Graduate Clinical Lecture

ON

SYMPTOMLESS HAEMATURIA.

DELIVERED AT THE MANCHESTER ROYAL INFIRMARY,

BY

ARTHUR H. BURGESS, F.R.C.S.Eng., M.B., M.Sc.(Vier.),

PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF MANCHESTER;
HONORARY SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

[Abstract.]

HAEMATURIA as a clinical manifestation is frequently met with, but—fortunately from the point of view of the diagnosis of its cause—is usually accompanied by other symptoms of urinary disorder: pain, frequency of micturition, pyuria, etc. Here I wish to draw attention to a very interesting group of cases in which haematuria is absolutely the only symptom of which the patient complains; apart from this the urinary functions are in every way normal.

The discovery that blood is present in the urine is more or less a matter of chance, the patient happening to notice the colour; many volunteer the statement that had they been blind they would never have known there was anything wrong. In some of these cases, however, if the bleeding is sufficiently profuse for blood clots to form, pain may be caused by their passage along the ureter or urethra; but such pain is a "side-issue," and, not being dependent upon the actual cause of the haematuria, does not remove the case from the class of "symptomless" haematurias. The great interest of these cases lies in the diagnosis of their cause, and this is a matter entirely of physical examination, absolutely unassisted by any description of subjective symptoms by the patient.

I have recently completed the clinical investigation of 100 cases of symptomless haematuria, with the following results:

A. The haematuria was of vesical origin in 65 cases:

1. Villous papilloma	41
2. Malignant growth	18
3. Enlargement of prostate	3
4. Ulceration from suture left after colporrhaphy	1
5. Simple "solitary" or "mucous" ulcer	1
6. Calculus fixed in post-prostatic pouch	1

B. The haematuria was of renal origin in 35 cases:

7. Bleeding not seen at the time of examination; cause unknown	14
8. Malignant growths (including hypernephroma)	9
9. Papilloma of the renal pelvis	2
10. Angelioma of a renal papilla	1
11. Renal calculus	3
12. Congenital cystic disease	1
13. Chronic nephritis, with small cysts	1
14. Mobile kidney	2
15. "Essential" haematuria	2

Fenwick and others have described cases in which a symptomless haematuria was the first, and for some time the only, manifestation of renal tuberculosis—just as sudden haemoptysis may precede for a long period any other evidence of pulmonary tuberculosis.

1 and 2.—The outstanding feature of a review of these figures is that, while almost every pathological lesion of the kidney and bladder may occasionally manifest itself as a symptomless haematuria, some form of new growth enormously preponderates. Excluding the 14 cases of renal origin which were not bleeding at the time of examination, and in which the kidney affected could not be determined, my series shows 71 new growths out of 86 cases—that is, 82.5 per cent. Of the 71 new growths, 44 were benign and 27 malignant: 12 were situated in the kidney (3 benign and 9 malignant) and 59 in the bladder (41 benign and 18 malignant). Taking all my cases of symptomless haematuria of known etiology, benign new growth was the cause in 51.1 per cent, and malignant new growth in 31.3 per cent. The diagnosis of simple from malignant growths of the bladder is not always possible by cystoscopic examination only, since both may have a villous surface; in the earlier cases of my series all the bladder growths were removed by suprapubic cystotomy and their nature determined by histological examination, but since 1913 the

deciding factor in most cases has been the effect upon them of treatment by the diathermic current applied through a cystoscope; its immediately beneficial effect upon benign growths, and its failure to produce more than very temporary, if any, benefit upon malignant growths, form such a striking contrast as to constitute a useful practical clinical test between innocency and malignancy. In view of the great preponderance of new growths, it is only natural that in any given case of symptomless haematuria the surgeon's first thought will turn to that, and especially to villous papilloma, as the most probable cause; the fact that in about one-third of all cases (31.3 per cent.) a malignant growth is present, possibly in an early and operable stage, serves only to enhance the importance of tracing the haematuria to its source at the earliest opportunity.

Among the causes, other than new growths, in my series were the following:

3. *Enlarged Prostate.*—In three cases bleeding was seen cystoscopically to come from an intravesical enlargement of the prostate, although none of the usual early symptoms of prostatic enlargement were present. There has been no recurrence of haemorrhage since prostatectomy.

4. *Ulceration from Suture.*—Here the blood was seen to come from an ulcer on the posterior wall of the bladder just behind the trigone; in the base of the ulcer a foreign body was seen, which proved to be a chromic catgut suture remaining after an operation of colporrhaphy three years previously; after its removal the ulcer healed readily. There was not the slightest encrustation of urinary salts upon the suture.

5. *Simple "Solitary" Ulcer.*—This patient, a male aged 27, was in hospital for varicose veins, when he commenced with haematuria, which rapidly became so profuse that when I first saw him he was passing almost pure blood—in fact, it clotted in the vessel. Cystoscopy was impossible, so I opened the bladder suprapubically, and found an ulcer three-quarters of an inch in diameter, on the posterior wall, slightly to the left of the middle line and just behind the trigone, and which was bleeding profusely. The bleeding was stopped by the canter, and never recurred. Some six years later this man again came under my observation, with tuberculosis of the left epididymis and vesicula seminalis; cystoscopy showed the bladder free from ulceration, though the scar of the former ulcer was plainly visible. Fenwick describes cases of simple "solitary" ulcer in which there has been no subsequent development of tuberculosis, but I think that, in my case, the original ulcer was probably of tuberculous origin, although no other evidence of tuberculosis in the body was then discovered. He died of generalized tuberculosis within a year of the second examination.

6. *Vesical Calculus.*—This was a male, aged 60, who had had two attacks of symptomless haematuria at an interval of two years. Cystoscopy showed an intravesical enlargement of the prostate with calculi in the post-prostatic pouch. These were removed, along with the prostate. There were one large and seven small calculi; the large one [shown at the lecture] was the most conspicuously stellate and "spiked" calculi I have met with, each primary "spike" ending in three or four secondary ones. That such a calculus should be unassociated with any pain or other symptoms except the two attacks of haematuria seems very remarkable, and is probably to be explained by its fixity in a post-prostatic pouch.

9, 10, 12, 13.—These conditions were discovered only after exploratory nephrotomy of the kidney to which the haemorrhage had been cystoscopically located, and the two former only after almost complete hemisection of the kidney, the renal pedicle having been previously clamped. In both cases of papilloma the growth was small, single, and situated in the lowest calyx, and was treated by local excision only, with subsequent suture of the kidney. The angioma was situated on one of the renal papillae towards the upper pole, was about the size of a green pea, and was similarly treated. One of the cases of papilloma had recurrent haematuria four years later; cystoscopy showed the bleeding to come from the same kidney (right), the left kidney acting normally. Nephrotomy showed considerable recurrence of the papillomatous condition, and I removed the kidney, since when there has been no further haemorrhage. The case of angioma and the second case of papilloma were free from recurrence five years later, but have been lost sight of since.

11. *Renal Calculus.*—One of my three cases was of particular interest, the cause of the haematuria not being recognized at the time. A female, middle-aged, was removed to a

fever hospital, with slight haematuria and slight desquamation of the skin, from a house in which some six weeks previously two cases of undoubted scarlet fever had occurred, she being considered to have a slight degree of post-scarlatinal nephritis. As the haematuria became rather bright red the possibility of villous papilloma of the bladder was considered, and I made a cystoscopic examination. I found a perfectly normal bladder and saw the blood coming from both ureteric orifices. The bleeding ceased entirely in a few days, and I heard nothing further of the case until seven years later, when, the haemorrhage recurring, she was admitted to my wards. Cystoscopy then showed the blood to be coming from the right ureteric orifice only. Radiography disclosed a large-branched calculus in each kidney, completely filling up the pelvis and calyces. Nephro-lithotomy was performed on the right side and three weeks later on the left, with complete arrest of the haemorrhage. This is the only occasion on which I have seen with the cystoscope blood issuing from both ureteric orifices simultaneously in a case of bilateral renal calculus, and such occasions must necessarily be exceedingly rare. A point to emphasize is that in bilateral renal calculus painless haematuria from one kidney may accompany typical renal colic, without haematuria, in the opposite kidney, and, unless a cystoscopic examination be made and the source of the bleeding definitely determined it might naturally be concluded that the bleeding was from the side of the renal colic. I have recently had such a case where the bleeding was so profuse as to threaten death from haemorrhage, and only a routine cystoscopy prevented the wrong—that is, the non-bleeding—kidney from being operated upon first.

14. *Mobile Kidney*.—In two cases, both males, the kidney to which the haemorrhage was traced was extremely mobile. Exploratory nephrotomy revealed no other abnormality, and nephropexy arrested the bleeding, which has not since recurred—twelve and eight years respectively having elapsed.

15. *"Essential" Haematuria*.—In two cases, the bleeding having been traced to one kidney, exploratory nephrotomy revealed no macroscopic cause, and a portion of renal parenchyma removed for histological examination showed a normal structure. The term "essential" haematuria has been applied to renal haemorrhage, the etiology of which cannot be determined after all the present known methods of urological investigation have been applied with negative result. The most recent writer on this subject, Dr. C. S. Levy,¹ of the Johns Hopkins Hospital, Baltimore, in reviewing thirty cases, evidently does not include exploratory nephrotomy in his methods of urological investigation, and thus instances of 9, 10, and 13 in my series would have been classed as "essential," although nephrotomy revealed a definite cause.

In clinically investigating a case of apparently symptomless haematuria we must first of all make sure, by microscopic detection of blood corpuscles, that it is really haematuria and not the rare condition of haemoglobinuria. Further, we must exclude general diseases that cause haematuria, such as haemophilia, scurvy-rickets, the group of anacemias, and the passive congestion of heart disease. Having decided that the haematuria results from some lesion in the urinary tract, we next require to investigate, in order of urgency, (1) the source of the haemorrhage, whether vesical or renal, and if the latter whether unilateral or bilateral; (2) the nature of the lesion causing it; and (3) the functional condition of the rest of the urinary tract. The physical characters of the blood—whether intimately mixed or not with the urine, whether bright red or dark red, whether associated with clots of any characteristic shape—although serving as a rough and ready guide to the source of the bleeding, are not sufficiently trustworthy to be relied upon in any given case. The brightest haematuria I have ever seen was proved cystoscopically to come from a kidney which subsequent operation showed to be the seat of a sarcoma; while in another case, where the blood was of a dark "porter" colour, intimately mixed with the urine, and associated with attacks of severe left renal colic, cystoscopy showed a large villous papilloma of the bladder almost occluding the left ureteric orifice. By cystoscopy alone can the source of the haemorrhage be determined with certainty, and its application should be regarded as a matter of urgency, particularly if the haemorrhage is actually going on. If the haematuria be of renal origin it is only at this time that the kidney at fault can be discovered; such opportunity, if missed, may not recur for a long period, during which, as we have seen, in about one-third of all cases a malignant growth will

be steadily progressing, and the only chance of its extirpation be lost. Too often does it happen that the practitioner's first efforts are directed not to ascertaining the source of the bleeding, but to immediately arresting it by keeping the patient in bed and administering morphine and internal styptics; though this may allay the alarm which many patients feel when they discover that they are passing blood with the urine, yet in the long run it would be of greater service rather to attempt to continue the haemorrhage until arrangements can be made for a cystoscopic examination to trace it to its source. Only in this manner will disease be located in its earlier and operable stages, and the present appalling mortality of malignant growths of the urinary tract be materially lessened.

Cystoscopy while bleeding is actually occurring will, if the haemorrhage be of renal origin, definitely indicate from which ureteric orifice the blood is escaping; if of vesical origin and not too profuse to obscure vision altogether, not only will the source of the haemorrhage be located but the lesion causing it will be seen. Difficulty will arise only where the bleeding is very profuse, but even here repeatedly washing out the bladder, combined with the introduction of a solution of adrenalin, will usually enable a view to be obtained; where this is found impossible this fact alone is strong presumptive evidence of a vesical origin.

Cystoscopy after cessation of the haemorrhage may fail to show its source: should it have been of vesical origin, then some lesion in the bladder sufficient to cause haemorrhage will be noted, and the absence of such indicates a renal source, although it does not show which kidney is at fault. A definitely abnormal appearance of one ureteric orifice suggests, though it does not prove, that the corresponding kidney is the offender; sometimes help is obtained by an assistant lightly compressing each loin, when, if unilateral haemorrhage be started, it suggests the pathological kidney. If bleeding cannot easily be induced, and if no renal tumour or other physical sign be present, then there is nothing for it but to wait until the haematuria recurs and to cystoscope during the attack.

Where the blood has been seen to issue from one ureteric orifice, then a thorough investigation must be instituted by all the usual urological methods to ascertain the pathological lesion in the corresponding kidney: careful palpation of the loin, a chemical, microscopic, and bacteriological examination of the mixed urine and possibly also of the separated urines after ureter catheterization, radiography, and pyelography. By these positive evidence may be obtained of certain conditions, such as calculus, tumour, or tuberculous; but if they yield negative evidence only, then the remaining procedure is an exploratory nephrotomy. Before undertaking this, inasmuch as it may disclose some pathological condition requiring nephrectomy, it is essential to investigate the functional capacity of the opposite kidney, and for this I rely most upon the "indigo-carmin" test, the efflux from each ureteric orifice being carefully watched through the cystoscope. Being assured of the efficiency of the opposite kidney, the bleeding kidney is then explored from the loin, the upper end of the ureter and the renal pelvis carefully examined from without, the renal pedicle clamped, and the renal parenchyma freely incised so as to expose the whole of the pelvis and calyces. If no macroscopic lesion be found, a slice of the parenchyma is removed for histological examination and the kidney carefully sutured by deep and superficial catgut sutures. The case must now be classed as an "essential" haematuria, and should the haemorrhage subsequently recur it may be treated medically, with the confidence that one has not overlooked a malignant growth; only if the haemorrhage becomes so profuse as to immediately threaten life should further operative treatment be considered, and this would take the form of nephrectomy.

In the paper already referred to, C. S. Levy traces the after-history of 30 cases of "essential" haematuria, at periods of from one month up to twelve years: 12 cases remained free from recurrence and 18 recurred. Of the 30 cases 5 only were operated upon: 1 by nephrectomy with cure, 3 by nephrotomy (1 without recurrence, 1 with recurrence five years later and twice since, and 1 with recurrence two and a half years later and five times since), and 1 by decapsulation, with recurrence after five years and thrice since; none of the patients developed tubercle, growth, or serious disease subsequently. Although one must admit that the results of operative treatment in true "essential" haematuria are not superior to those of medical or expectant treatment, yet personally I hesitate to class a case as "essential" until an

exploratory nephrotomy has proved negative—one has the uncomfortable feeling that an early case of malignant growth might be overlooked. The operation in itself is not a serious risk; it may disclose some curable condition which otherwise might have been missed until it had reached an advanced stage, and even should it prove negative it allows one to regard without alarm any future recurrence of the haematuria.

In conclusion let me again emphasize the great importance, when called to a case of symptomless haematuria, of treating the patient rather than the haemorrhage, and of not attempting to arrest the bleeding until, by means of cystoscopy, it has been traced to its source.

An Address

ON THE

PERNICIOUS VOMITING OF PREGNANCY.*

BY

CARLTON OLDFIELD, M.D., F.R.C.S.,

HONORARY OBSTETRIC SURGEON, GENERAL INFIRMARY, LEEDS; LECTURER IN GYNAECOLOGY, LEEDS UNIVERSITY.

For more than twenty years I have been of the opinion that all cases of pernicious vomiting of pregnancy are neurotic in origin, and I have treated the condition accordingly. During this period I have met with about 35 cases, but for the purpose of this address I am considering only 29 of them, as the others remained at home for treatment. Of these 29 cases, 5 were in-patients under my care at the Leeds General Infirmary, 17 in the Hospital for Women and Children, Leeds, and the remaining 7 were in nursing homes. All the patients recovered, and in only one case was abortion induced. The advantage of the treatment that I carry out is that the vomiting usually ceases immediately, and induction of abortion is seldom or never necessary. Indeed, I do not know of any grave illness such as this which responds to treatment so suddenly. By contrast the usual methods of treatment, multitudinous in variety and well known to you all, are prolonged and dissatisfying, and often end in the induction of abortion, which in this disease is attended by a serious risk to the life of the mother.

I will state exactly what I do; nothing could be more simple. The patient is admitted to a hospital or nursing home and put on ordinary diet at once. The nurses are told, if they have not nursed similar cases of mine before, that the vomiting is due to neurosis, that a bowl must not be provided even if the patient should vomit, and that the words "vomit" and "sickness" must not be mentioned in the presence of the patient. They must just expect her to take her food like other patients in the ward, and must not try to persuade her to do so. As a rule the patient will at once take the full ordinary diet and retain it, but sometimes only a small portion is taken for the first day or two, part of which may occasionally be vomited. If any vomiting occurs the patient is assured that it will soon stop and that she will soon be quite well. In most cases a rectal infusion of 4 per cent. glucose is given, and, as a rule, continuously by the drop method. This relieves the thirst and the feeling of exhaustion, and, by diminishing the acidosis, I think it lessens the tendency to vomit. No drugs are used, except a purgative when it seems desirable. There is no necessity for psycho-therapy as ordinarily carried out in medical and surgical cases. Hospital and other cases do much better when they are in a ward than in a separate room.

Simple though this treatment is in principle and in practice, difficulties sometimes occur, and some of these I must mention. It may seem strange to you, but the patients are sometimes reluctant to go to a hospital or nursing home. If induction of abortion, which the doctor often suggests, were advised, there would probably be no difficulty in persuading the patient to leave home; but when an operation is not necessary it is not always easy to convince her of the advantage of institutional treatment. In the severest cases, however, there is seldom any difficulty when the patient and her friends are assured that she will bear the journey satisfactorily.

In August, 1921, I saw a primigravida in consultation with her doctor in a town about thirty miles from Leeds. She was about eight weeks pregnant and had been vomiting for about three weeks. For two weeks she had been under treatment for pernicious vomiting and for several days had not retained any food. Vomiting and retching had been almost incessant for three

or four days. Various medicines had been tried and glucose given by the rectum. The urine had given a strong reaction for acetone when tested a week previously. Her face was drawn, her eyes sunken; she was exhausted and distressed. The pulse was 120 a minute. Her doctor had arrived at the conclusion that nothing but induction of abortion would save her. Her friends were very reluctant for a while to allow her to be taken to Leeds, but after being told that the journey would not harm her, that the vomiting would cease when she arrived there, and that she would soon be better, they agreed to take her. She vomited once on arrival and had a meal of tea, bread-and-butter, and stewed apple as soon as she was settled in bed. She kept it, slept all night, and took coffee, bacon and egg, toast and marmalade for breakfast next morning. Ordinary diet was continued during the ten days she was in Leeds and the vomiting did not recur. When she went home the patient looked and felt quite well.

I will now narrate a case which illustrates the advisability of the patient being placed directly under the daily charge and observation of the obstetric surgeon who advises the treatment. With the exception of this all the cases were treated in Leeds, where I can obtain nurses who have entire faith in the treatment.

The patient was a primigravida, aged about 30, who had been ailing and had had albumin in her urine for four or five years. She was eight weeks pregnant. She had vomited severely for two weeks, and had been in a nursing home in a neighbouring town for about a week and fed with small quantities of Benger's and similar food. This was usually returned, and so were water and tea. She looked very ill, and I pressed her husband and her doctor to send her to Leeds. As they refused, a trial was given to ordinary diet, to the obvious amusement of her incredulous nurses, and glucose enemata were ordered. The vomiting persisted, and when I saw her again three days later she was no better. I noticed at once a capacious bowel still remaining at the bedside, which, in my opinion, was a contributory cause of the persistence of the vomiting. I again expressed my conviction that she would soon be well if she came to Leeds, and advised against induction of abortion, but she remained where she was, and was treated by glucose infusion given continuously and by semi-starvation diet. Sugar, diacetic acid, and albumin were present in the urine. Vomiting continued in varying degrees for some weeks, and eventually she recovered, but the sugar in the urine persisted until after the labour at full time, when she was safely delivered of a weakly child weighing 4 lb. It is my belief that if my advice had been accepted this patient would have recovered much sooner and the life and health of herself and child would have escaped the serious dangers through which they passed.

In three or four cases in which the vomiting has persisted after admission to hospital I have suspected that the patient wished to get rid of her pregnancy. One of them acknowledged, after spontaneous abortion at the sixth month of pregnancy, that she was "determined not to go through with it," and that she had produced the vomiting by putting her finger into her pharynx. In some other instances I have spoken seriously to the patient, and have pointed out the danger of the persistent vomiting and of induced abortion, and afterwards, with one exception, the symptoms have soon cleared up. In the exception, however, abortion was induced. She was sent to the Hospital for Women and Children, Leeds, by her doctor, who told me and the patient that induction was necessary to save her life. She improved after admission, but relapsed again after her friends had visited her and told her that their family doctor said she must have induction of abortion or she would die. She was alternately better and worse for two weeks, the bad turns always following visiting days, and in the end I gave up the struggle and evacuated the uterus.

I trust that I have explained clearly and fully enough the treatment carried out and the difficulties met with, but I would like to emphasize the necessity of having nurses who believe in the treatment. I am occasionally asked if my results are good in toxicæmic cases. My reply is that most of my cases are toxicæmic, but I regard the toxicæmia as a result and not as a cause of the vomiting. Many have been seriously ill and emaciated and have had bile-stained conjunctivæ and bile in their urine. Such cases recover as quickly as the less severe and their recovery is more dramatic.

Perhaps I ought to say a word or two about the pathology of this condition, although I am mainly concerned with its treatment. Tweedy¹ thinks that the pernicious vomiting of pregnancy is due to food poisoning; Hirst² that abnormal secretions of the corpus luteum cause it. These theories are highly speculative and have little evidence to support them. Most authorities appear to favour the view that some toxic substance is absorbed from the developing ovum. This seems a more reasonable hypothesis, because there is no condition, apart from pregnancy, like pernicious vomiting. One of my cases, however, seems to offer evidence against it, for the vomiting continued, although the ovum was almost

* Abridged from the valedictory presidential address at the North of England Obstetrical and Gynaecological Society, January 20th, 1922.

completely decomposed. Pathological investigations, which have been carried out extensively, have been mostly concerned with the character of the metabolic disturbance rather than with its primary cause. Some workers³ have concluded that the chief disturbance is one of carbohydrate metabolism, others of nitrogenous metabolism. Amongst the latter is Whitridge Williams,⁴ who, in 1905 and 1906, expressed the opinion that the ammonia coefficient is valuable in the diagnosis of the severity and the variety of the disease and also as a guide to treatment, more particularly with respect to the question of induction of abortion. In a later paper⁵ he admits that he overvalued the significance of the ammonia coefficient. He also says: "In my experience neurotic vomiting is the variety most frequently encountered,"⁶ and mentions a case in which the vomiting ceased at once when he decided to induce abortion. He believes, however, that in some cases a primary toxæmia is the cause of the vomiting, but to my mind his arguments in favour of this view are not convincing. Pathological investigations into the changes in the urine have not been made in my cases, chiefly because the work seemed unnecessary for purposes of treatment and prognosis, and also because the vomiting has usually ceased before the investigations could have been carried out.

My clinical experience leaves me in no doubt that all my cases are of neurotic origin, and I believe that all cases of pernicious vomiting of pregnancy are of this variety, and that the more severe cases are later or advanced stages of neurotic vomiting.

CONCLUSIONS.

1. Vomiting of pregnancy can be cured quickly as a rule and with a high degree of certainty by the removal of the patient to a hospital or nursing home and by feeding on ordinary diet.
2. Induction of abortion is seldom or never necessary.
3. The so-called toxæmic cases are usually, if not always, later stage of neurotic vomiting.

SOME COMMON DEFECTS OF DIET AND THEIR PATHOLOGICAL SIGNIFICANCE.

ABSTRACT OF THE OLIVER-SHARPEY LECTURES DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS,

BY

E. MELLANBY, M.D.

LECTURE I.

PROFESSOR MELLANBY began by saying that up to a few years ago the subject of nutrition was completely dominated by German ideas and German work, more particularly the very great work of Ruebner, whose point of view, briefly, was that if a person ate enough to give rise to sufficient energy that was all that was necessary. Ruebner put forward the generalization known as the theory of isodynamic equivalents—that is to say, that most foodstuffs were equally good so long as they provided sufficient energy for a man's body. That, obviously, was to treat a man like an engine, and to some extent it was justifiable. Almost the only qualification in Ruebner's theory of isodynamic equivalents of foodstuffs was that the food must contain a small quantity—about 4 per cent.—of protein. This theory of Ruebner was completely demolished by F. G. Hopkins in his Huxley lecture,¹ in which the subject of nutrition and dietetics was treated from a more or less philosophical standpoint. Hopkins showed that Ruebner in stating that the energy given by food was its only limiting factor was quite wrong. The energy was the limiting factor in a diet only when that diet was complete—that is to say, when it was a perfect diet—but there could be all kinds of imperfection in diets, such as insufficient carbohydrates, of imperfect protein, and so on. Hopkins put forward the theory known as the theory of the minimum, which simply meant that every food in order to produce perfect health must have at least a minimum amount of certain constituents.

Lesson from the Eskimo.

In his own two lectures Professor Mellanby intended to approach the subject, not from the philosophical point of

view of Hopkins, but by way of practical demonstration of certain errors in modern diet and their pathological consequences. Take, in the first place, the primitive Eskimo. This man had perfect teeth, perfectly arranged in very hard, well-formed jaws. His limb bones also were very strong. His diet consisted of muscle tissue and fat. When he killed his animal to eat he saved the blood in order to get sodium chloride in that way. He regarded the glandular structures of the animals he ate as dainties; he ate bone marrow and also the softer parts of the bones, such as the epiphyseal ends and the ribs. But, on the other hand, the modern Alaskan, whose diet depended upon stored goods, such as canned products, both cereals and meats, had teeth which were poorly calcified, and he was just as susceptible to caries as the man in a more highly-civilized community. The same thing was found if one took the African or the West Indian negro in his natural habitat, where his diet consisted of fruit and vegetables and fresh natural products, and compared him with the negro in American cities. In the one case he had beautiful teeth and hard bones; in the other he was apt to show bad teeth, rickets, and general physical deterioration. The Icelanders, again, up to the middle of the last century were free from caries; their diet had consisted of milk, mutton, fish and fowl, and eggs of wild fowl. Now they had a modern dietary, with cereals, sugar, and so on, and had got caries and other degenerative conditions.

One other fact might be pointed out, although, perhaps, it was a digression. The Eskimos, living in their natural habitat, before the introduction of modern diets, got no cancer, and the same was true of the Icelanders. It was only with the introduction of these modern diets that cancer was becoming common in Iceland, and was now found actually among the Eskimo. This was an interesting observation, because here they had two diseases which were really diseases of civilization, rickets and cancer—and in one case a disease of civilization, cancer, was due to diet, while in the other it was just possible that there might be a similar relation. He did not mean that cancerous growths might not be forthcoming with a perfect diet, but it might be that the malignancy was due to wrong diet. That, however, was purely supposition, and without experimental basis.

The Change in Modern Diet.

It was necessary to ask why modern dietary had changed. Largely it was because people were taking more and more to urban life; fewer were actual food producers. The food had to be brought into cities from considerable distances, and preference was given to those foods which could be easily transported and were not readily destroyed by bacteria. Economic conditions were such that recourse had to be generally made to foods which could be easily and abundantly produced at comparatively small cost. The cheapest foods compatible with life were cereals, pulses, foreign meat, and vegetable margarines. But it was not only those who could not afford richer diets who suffered; people who were able to have a certain choice suffered also. It must be agreed that taste was not a very reliable guide to a proper dietary. Some people had a strong belief in physiological aesthetics, which meant that if a person liked a thing it was good for him. The believer in physiological aesthetics would point to the fact that the average man preferred butter to margarine. But, on the other hand, it could also be pointed out that the average man preferred the fat of bacon and pig fat generally to the fat of beef or mutton, and there was no doubt at all that beef fat and mutton fat were very much better, while probably the best fat of all which the laboratory worker came across was cod-liver oil, which the average man disliked. It might also be argued that the average man liked cereals, and ate large amounts of bread and also of sugar, and the value of these things as foods seemed to justify his taste; but how many people as a matter of choice drank milk as a beverage? Those who drank milk did so more or less as a duty, yet it was difficult to think of a food which had greater value.

Altogether, with regard to taste and appetite, it must be said that something had gone wrong. Nature had overdone things. Nature had seen that there were some things which were essential to life, like carbohydrates in the diet, and had laid so much stress on those constituents as to appear to forget that there might be other things which were equally important. The habit of rather excessive meat-eating was another instance. Most people liked meat to an extent which was hardly justified by the part it played in nutrition. An instance of taste going wholly wrong was the desire of many

people for acid and highly flavoured foods. Another reason why modern dietetic conceptions were often wrong was because, until recently, there had not been a reasonable standard for health. A child was found, for example, not only to like cereals and sugars, but apparently to flourish on them, growing fat and contented and lethargic, and the tendency was to regard weight as the criterion of health. The trouble was that the state of under-nutrition was not commonly appreciated. Malnutrition was understood when the child wasted away or developed tuberculosis, but more ought to be known about the state of under-nutrition before any extreme manifestations made their appearance.

Experimental Work on Foods.

The lecturer went on to detail some experiments on animals in regard to the effect of carbohydrates on growth, and pointed out that more activity was got by increasing the fat in the diet than by increasing the carbohydrates. Foods could be divided into two large groups: the first consisted of products such as milk, butter, cream, cheese, eggs, and green vegetables, like cabbage and lettuce; the other was made up of cereals (wheat, rice, oatmeal, maize, and all the prepared products made up of such things), vegetable margarine, lard, meat (including pork), also sugar, jam, potatoes, and tea, coffee, and cocoa. Of the first group the average man really got very little. An authoritative estimate showed that the amount of milk consumed per diem (including milk products) was equal only to a quarter of a pint a head of the population. Cheese was rather popular, but green vegetables were not commonly favoured, and his experience in hospital was that it was difficult to get patients to eat them at all. The second group of foods he had just catalogued was wrong in several respects; it lacked sodium, chlorine, calcium, anti-scorbutic vitamin, and if the fat of beef and mutton were taken away—and most people did leave such fat on their plates—the diet was also lacking in fat-soluble vitamin. The foods which were rich in calcium and fat-soluble vitamin were egg-yolk, cow's milk, human milk, and green vegetables; foods poor in this respect were white bread, rice (polished), potatoes, margarine, sugar, jam, and lean meat. He mentioned that from 1912 to 1917 the cases of xerophthalmia in Copenhagen increased in number steadily and considerably, but as soon as the Danish Government in 1917 prevented the export of butter, thereby making it available for home consumption, so that there was a sufficient quantity for each person, the whole trouble entirely disappeared. Just as in nature this fat-soluble vitamin was associated with calcium; so in the body there was experimental evidence for believing that calcium and something at any rate closely resembling fat-soluble vitamin worked in harmony—that, in fact, the body could not retain calcium, however much of it there might be in the food, if it did not have at the same time some of this vitamin.

The lecturer next described a basal diet for certain experiments on the production of rickets in dogs. The diet consisted of separated milk, white bread, yeast, orange juice, lean meat, and sodium chloride. If for the fat such a thing as linseed oil were used, rickets was produced; if cod-liver oil were used, there was no rickets. He had not been able definitely to affirm that this antirachitic vitamin was actually the fat-soluble, but it almost certainly was. Fats might be divided from the point of view of antirachitic action as follows:

Good.	Moderate.	Poor.
Cod-liver oil.	Lard.	Linseed oil.
Beef suet.	Cocconut oil.	Olive oil.
Butter.	Rape.	Palm-kernel oil
Egg-yolk.	Cottonseed oil.	Babassu oil.

The hardened fats—hardened to make them tasteless and used for adding to margarine and so forth—were also very poor from the point of view of rickets prevention. Among the useful fats from this point of view was yolk of egg, which contained something absent from the white.

Diets deficient in fat-soluble vitamin had been found—as the result of experiments by Mrs. Mellanby on dogs—to give rise to a poor growth of the jaws and alveolar process, irregular placing of the teeth, delayed eruption and slow eruption, thin and defective enamel, teeth light in weight for their size, poor development of the gingival margin, as well as, "generally speaking, a diminished resistance to disease. Dogs fed on cod-liver oil had good teeth, those fed on butter were moderately good from the dental point of view, though in certain respects defective, while those fed on linseed oil showed very bad formation of teeth and the tooth substance

as shown by a microscopical examination was defective. It had not been proved that this experimental production of badly formed teeth solved the problem of caries. Mrs. Mellanby had not produced caries in these animals, and the fact remained to be proved. One could only say that it was probable that animals or children with badly formed teeth would be more susceptible to caries. He showed microscopical slides to illustrate the remarkable changes of dentine according to the type of fat used.

CALCIUM DEFICIENCIES: THEIR TREATMENT BY PARATHYROID.

BY

W. R. GROVE, M.D.,

HONORARY SURGEON, HUNTINGDON COUNTY HOSPITAL;

AND

H. W. C. VINES, M.B.,

DEPT MEMORIAL RESEARCH FELLOW, CAMBRIDGE.

In a previous paper evidence was brought forward to show that in the circulating blood of the normal individual the calcium is present in two forms, ionized and combined.¹ When coagulation of the blood occurs, the calcium in the exuded serum is found to be all in the ionized form, the normal amount present being about 10.5 mg. of calcium per cent. In certain ulcerative conditions² it was found that there occurred a deviation from the normal in the calcium content of the serum, some of the calcium being present in the combined form. In all cases of varicose ulcer when the blood was examined this abnormality was found, and in the belief that this might be concerned in maintaining the chronicity of the ulceration measures were taken to increase the ionic fraction of the calcium in the serum. The intramuscular injection of ionized calcium salts had a definite effect in promoting the commencement of healing in the ulcers; the oral administration of calcium had none. But the injections did not appear to have the power to cause complete healing, and it was not till parathyroid substance was given orally that complete healing was obtained. Further, it was observed that healing of the ulcer and rise in the ionic calcium content of the serum ran approximately parallel. From these observations it was concluded that the toxic substance produced by the varicose condition in some way injured the parathyroid glands, and also combined with some of the ionized calcium of the blood. In this way the calcium balance of the blood became disturbed, and the parathyroids were not able to rectify it. Finally, the decrease in the plasma of one of its normal constituents would tend to lower the resistance of the tissues, so that the ulceration, started by slight local trauma, would tend to occur within the varicose area, where nutrition of the tissues is least effective.

The present paper forms an account of the application of these views to a considerably wider field of disease. The conditions dealt with may be classed generally as chronic states of a toxic or infective origin, and, though they have this common factor, they are classified in medical thought and literature as separate and usually unconnected diseases. It is therefore necessary to lay some stress on the mode of action of parathyroid substance, so that the appearance of a claim to its action as a universal panacea may be avoided.

The mode of action of parathyroid is essentially physiological; it is most probably a double action—a more or less specific action on calcium metabolism combined with, or resulting in, a generalized stimulation of metabolism as a whole. It is an aid in the fight against infection of the chronic type, not by its specific action on the infecting organism, but because it places the tissue cells under the most favourable conditions for an adequate resistance; and among the factors concerned in this process not the least important is the maintenance of a proper calcium balance in the plasma. If the tissue resistance is adequate it is immaterial whether the agent that is actively harmful is of bacterial origin or otherwise. If a deficiency of ionic calcium in the serum is a factor in the decrease of tissue resistance, then parathyroid therapy should be of value in those cases where such deficiency exists; and it is explicitly stated that parathyroid is not a specific method of cure for such conditions, but rather a rational method of assisting the cellular

elements to exercise their proper defensive mechanisms. If, then, it is realized that the majority of chronic diseases in medicine are due to protracted absorption of toxic substances from a septic focus, that such absorption is accompanied by a decrease in the ionic calcium of the blood, and that the parathyroid glands are the regulators of calcium metabolism, the claims which are put forward in the following paragraphs for the value of parathyroid therapy in such states will not seem so unreasonable as they may at first appear.

Over one hundred cases of chronic states have been treated by parathyroid therapy, in all of which variations in serum calcium have been observed during treatment. In all cases the sequence of events is similar: improvement commences when the amount of ionic calcium in the serum begins to approach the normal figure. In addition a considerable number of cases in which the calcium examinations were not made have been treated. The following table may give some indication of the types of disease amenable to this method of treatment, though it is fully realized that it may be applied successfully to many other conditions outside this particular series:

Table of Diseases Amenable to Treatment by Parathyroid.

I. Chronic Toxicities.

- (a) *Ulcerative.*—Varicose ulcer; gastric ulcer; duodenal ulcer; erosion of cervix uteri; gumma.
- (b) *Suppurative.*—Nasal sinusitis; tonsillitis; pyorrhoea; otitis media; bacilluria.
- (c) *Non-suppurative.*—Rheumatic group: Rheumatoid arthritis; osteo-arthritis; chronic rheumatism. Arterio-sclerosis. Eczema; chlorosis; sciatica.

II. Conditions of Uncertain Cause.

Menorrhagia; prostatic hypertrophy; urticaria.

While these cases represent conditions where toxic processes have been at work over varying periods, the following observations afford some evidence of the manner in which an acute attack may affect the calcium of the serum. The symptoms ran a natural course without special treatment against the calcium deficiency.

I. On November 26th the patient's temperature was 102°. On the 27th lymphangitis of the leg became apparent; the temperature remained high, but fell to normal on November 29th. On this day the calcium content of the serum was as follows: Combined calcium 1.4 mg. per cent., ionic calcium 8.5—total, 9.9 mg. per cent. On December 2nd the combined calcium was 0.8, ionic 9.6—total, 10.4 mg. per cent. On December 8th all the calcium was ionized (10.4 mg. per cent.). It was not till the next day, however, that the patient felt any pleasure in work.

II. A mild influenzal attack. The patient had sore throat at midday on January 5th; rigor in the evening. Temperature 101°, pulse 80, respirations 18. Calcium content of serum: Combined calcium 1.8, ionic calcium 8.3—total, 10.1 mg. per cent. On January 6th the temperature was 100°. Serum calcium: Combined 1.5, ionic 8.3—total 9.8 mg. per cent. The following day the temperature was normal; combined calcium 1.0, ionic 9.1—total, 10.1 mg. per cent. On January 8th the serum calcium was normal (10.1 mg. per cent.).

The next two instances give the results of vaccine injections in the same individual. The vaccine used was the polyvalent vaccine for prophylaxis against influenza.

III. On January 18th, before injection, the serum calcium was normal (10.7 mg. per cent.); 1 c.cm. vaccine injected. Twelve hours after injection: Combined calcium 2.8, ionic 7.1—total, 9.9 mg. per cent. Thirty-six hours after injection the calcium content was as follows: Combined calcium 1.9, ionic 8.8—total, 10.7 mg. per cent.

Three weeks later a second injection was given and a similar result obtained. Before injection the serum calcium was normal (10.7 mg. per cent.). Twelve hours after injection the calcium content of the serum was: Combined calcium 2.8, ionic calcium 7.9—total, 10.7 mg. per cent. Twenty-four hours after injection: Combined calcium 2.1, ionic 8.6—total, 10.7 mg. per cent. Thirty-six hours after injection the serum calcium was normal.

In both instances the height of the local reaction was about twenty-four hours after injection, but in the second instance this reaction was less and the calcium returned more quickly to normal. Though acute conditions have not yet been studied to any great extent, there seems to be some evidence of an early disturbance of calcium metabolism.

Administration of Parathyroid Substance.

In order to standardize results to some extent, the same preparation of parathyroid (Parke, Davis and Co.) has been used throughout. Usually one-tenth of a grain has been given night and morning for the first four to seven days, and subsequently one-tenth of a grain daily. Such treatment may be continued for a considerable time; in no case has there been any symptom of overdosage. In the early stages

of treatment certain conditions may arise which may be alarming. The most usual is an exacerbation of the septic process responsible for the general condition; a purulent discharge may increase in amount or may appear where it was absent before; a chronic appendix may become acute and necessitate operation; very frequently a tooth may start to ache. In three cases it happened that while some other complaint was being treated with parathyroid the patient had an attack of erythema—almost erysipelas of the face—and in all three cases there was marked sepsis of the teeth. A case of this type may be quoted.

A long-standing case with a small tuberculous sinus from the hip was found to have a marked deficiency in ionic calcium. After a week's parathyroid treatment (gr. 1/10 daily) the discharge increased until there was a quite severe local condition and the old healed tracks opened again. It took two months' parathyroid treatment to get the blood normal again, and then healing recommenced. At the present time, four months from the commencement of treatment, the sinus is about the same size as at the beginning, but there is evidence that the healing is progressive and not stationary as it was previously.

The increase of suppuration at the site of the septic focus suggests strongly that the parathyroid given by the mouth is producing a stimulation of the natural defensive mechanisms of the body; that it is, in fact, acting in a physiological manner and not specifically on the invading organism. If such is indeed the case, then its use in all forms of chronic infection can be readily understood.

The groups of cases set out in the table may now be considered and cases quoted from them as typical instances of the effects of parathyroid treatment.

Ulcerative Conditions.

Varicose Ulcers.—All the cases of this condition mentioned in the previous paper have remained healed, and a good many more have been treated with success. In two recent cases the ulcers were less than a quarter of an inch in diameter, very painful, and very resistant to parathyroid treatment. In both cases a septic condition of the gums was found, and after this had been remedied the ulcers healed. A further examination of the cases of varicose ulcer described in the previous paper revealed the presence of a pre-existing septic focus. In phlebitis of varicose veins calcium deficiency has also been found, and the more acute symptoms have subsided rapidly under parathyroid treatment. Here again the removal of septic foci in the teeth has hastened the disappearance of symptoms.

Gastric and Duodenal Ulcer.—Twelve cases of this diagnosis have been examined for calcium deficiency, and in all deficiency was present. It is not easy, however, to found a diagnosis or prognosis on purely clinical evidence or on the results of parathyroid treatment without some confirmation from x-ray examination or from some other evidence. Several cases have ultimately proved to be carcinoma in some form, although the early symptoms or results of treatment seemed to point to a simple ulceration. In such cases, although the patient may appear to be much improved physically, abdominal tenderness does not disappear completely. In cases which are not malignant the abdominal tenderness usually vanishes completely, the pallor is lost, the appetite increases, and the patient appears to take a much greater interest in his work and general life. Many of the cases in which there is calcium deficiency are very depressed, but the depression is lost as the calcium deficiency is removed; it is possible that many cases of neurasthenia are in reality due to toxic absorption and deficiency of ionic calcium. The two following cases may be quoted:

J. W., aged 56, had severe haematemesis six years ago. Last year he had a similar attack. He had always been very careful about his diet, but had pain regularly about two hours after meals. When he came under observation there was tenderness over the right rectus about two inches from the costal margin. On October 29th his serum calcium content was as follows: Combined calcium 0.5, ionic 7.29—total, 7.79 mg. per cent. He was given parathyroid gr. 1/10 daily, and on November 15th his serum calcium was normal. On December 5th he had no pain or tenderness; he states that for years he had never been able to eat so well.

Miss K., aged 50. For many years she had had pain two hours after food and at night. She had been seen by many doctors and her condition had always been diagnosed as duodenal ulcer. But so far as she knows she had not had either haematemesis or melaena. On October 28th the serum calcium content showed: Combined calcium 2.6, ionic 7.45—total, 10.05 mg. per cent. She was put on parathyroid daily, and on November 2nd the serum calcium was normal. By December 6th the patient was taking parathyroid gr. 1/10 twice a week, and was eating food without caution as she had not done for years.

On December 29th she said that she had been quite well till Christmas Day, when she ate a mince-pie; the pain returned that night and was still continuing. Tenderness was obvious in the same place as before. Serum calcium: Combined 1.2, ionic 8.5—total, 9.7 mg. per cent. She was put back to parathyroid daily.

On January 12th she had had no pain for three days, but there was still tenderness. A wisdom tooth was suspected of sepsis, and she admitted tenderness there. Serum calcium: Combined 1.2, ionic 7.3—total, 8.5 mg. per cent.

She did not have the tooth removed till February 6th, and there was an abscess at its root. At the time of writing she continues well, without any precautions as to diet, without pain, and the tenderness seems to have disappeared. She now refuses to give up taking parathyroid since she puts down her relapse at Christmas to the dose having been diminished too soon.

Gumma.—Although only one case of gumma has been treated in this way it is of sufficient interest to warrant its special mention.

Miss E., a chronic epileptic, aged 41, had a gumma of the left cheek which had been very resistant to specific treatment for eighteen months. On November 9th she had begun her third series of neo-salvarsan injections, which had been alternated with mercurial injections and mercury and iodide by the month. The gumma was about the size of a florin. Serum calcium: Combined calcium 1.7, ionic 7.9—total, 9.6 mg. per cent. The patient was given parathyroid gr. 1/10 night and morning, and the injections stopped. On November 16th the serum calcium was normal; ulcer healing well. Parathyroid reduced to gr. 1/10 daily. On November 21st the ulcer was completely healed, and the patient stated that she felt better than she had done for months.

The parathyroid was gradually dropped to once a week after a month's treatment, and the ulcer remains healed, although she has had no further specific treatment. It is of considerable interest to notice that during parathyroid treatment the epileptic fits decreased to about one in three weeks from two or three daily at a few days' interval. This is in accordance with the results obtained by other investigators.

Suppurative Conditions.

Nasal Infections.—In these conditions there is a focus of toxic absorption situated in the accessory air sinuses of the nose—an infection which is difficult to treat, and which may also be combined with a greater or less degree of ulceration in the affected area. Deficiency of ionic calcium has usually been found in such cases, and the treatment by parathyroid has given encouraging results, as is shown in the following two cases:

Mrs. S., aged 41, had a foul nasal discharge for years, and for some months it had been getting worse, so that she could not breathe through either nostril, and used some ten or twelve handkerchiefs a day. She had been told that it was due to ethmoid disease, and had been promised alleviation by operation, but had had to wait for a bed in hospital. On October 29th the calcium content of the serum showed: Combined calcium 2.3, ionic 6.1—total, 8.4 mg. per cent. She was given parathyroid gr. 1/10 daily. By November 11th she was breathing easily through the nose, used fewer handkerchiefs, and the discharge was whiter and less foul. Serum calcium: Combined 2.2, ionic 7.4—total, 9.6 mg. per cent.

On December 24th she had had practically no discharge for ten days; there was but a little thickness in the throat in the morning; the mouth was shut during sleep, and the patient was generally better than she had been for the last two years. Serum calcium: Combined 0.1, ionic 10.0 mg. per cent.—that is, practically normal. March 2nd: Patient stated that for years she had not been so comfortable. In January she thought she was quite well and dropped parathyroid, but slight symptoms returned, and she is now taking it daily, and keeping apparently well.

Miss R., aged 62, all her life had had nasal trouble, and as a girl had to use douches; she had always refused operation. Twelve months ago she had a troublesome iritis; six months ago a prolonged and difficult conjunctivitis with dacryocystitis, all traced to nasal infection. On November 12th the conjunctivitis returned. Serum calcium: Combined 0.8, ionic 8.0—total, 8.8 mg. per cent. Parathyroid given. By November 24th the eye was well, the nasal discharge less, and the patient was feeling better than she had done for weeks. Serum calcium: Combined 0.9, ionic 9.5—total, 10.4 mg. per cent. (almost normal).

January 16th: Has had no relapse, though there is still some discharge. Serum calcium: Combined 0.7, ionic 9.4—total 10.1 mg. per cent.

She continues well at the time of writing, and is satisfied that the discharge is steadily improving and that she can do her work better than previously.

In both cases the only form of treatment used has been the oral administration of parathyroid; both of them show that a long time may elapse before the serum calcium returns to normal, although signs of improvement commence when the ionic calcium starts to increase.

One case of nasal infection has not been so successful; he had been operated on, but the result was not satisfactory, and he had been treated with vaccines. In October calcium deficiency was observed and parathyroid was given in addition to the vaccine. After three months there had been no improvement, possibly owing to the previously mentioned

action of vaccine injections on the ionic calcium of the blood. For the last month he has had parathyroid alone, and some improvement has occurred, though the outcome is still uncertain. One or two single cases of septic states deserve mention.

Chronic Tonsillitis.—The patient had chronically enlarged and septic tonsils, but refused to have them removed. A year ago he was operated on for appendicitis. Since then he has had an attack of quinsy in both tonsils. On November 7th the serum calcium was: Combined 2.2, ionic 7.7—total, 9.9 mg. per cent. Parathyroid gr. 1/10 given daily. On November 25th the serum calcium was normal. He felt markedly better than he had done for some time, and the tonsils were smaller. He continues in perfect health.

Herpes Zoster and Iritis.—Mr. B., aged 69, on September 9th, while away from home, had an attack of herpes zoster on the left side of the head, involving the eye. The eye caused some anxiety and he was sent to the London Hospital, where he remained six weeks. On January 13th, when he returned home, there was ulceration of the cornea and iritis. Light only could be distinguished with the eye, which was much inflamed. Serum calcium: Combined calcium 2.0, ionic 7.3—total, 9.3 mg. per cent. Parathyroid given.

On January 22nd the ulceration seemed to be healed, but the cornea was steamy and there was much chemosis; he could distinguish objects, and the sight was improving. Serum calcium: Combined 0.6, ionic 8.6—total 9.2 mg. per cent.

He went on improving for a few days more, and then for a fortnight remained at a standstill. He may have been absorbing toxins from the gut, as after a brisk purge improvement recommenced. By the end of February the chemosis had practically disappeared, and there was but a slight ground-glass appearance to his vision. He could read medium large print with the affected eye, and said that it was improving daily.

In another case there was traumatic cataract, iritis, and later a small hypopyon due to piercing the cornea with a thorn. After a month's treatment with parathyroid combined with the removal of some septic teeth the lesion healed. In a case of chronic otitis media parathyroid treatment was followed by a temporary exacerbation of the discharge, but at the time of writing the aural discharge has practically ceased. Two cases of bacilluria (probably *B. coli*) were treated in the same way. Both were of some years' standing, and suffered during the attacks from extreme depression or neurasthenia; in both the ionic calcium was deficient. One was obviously suffering from septic teeth, and in the other, while under parathyroid treatment, one tooth became painful and another became so loose that it could almost be pulled out. The former case had been treated by an antegenous vaccine but had always relapsed, and under parathyroid he is better than he has been before. In both the depression had ceased, and improvement is encouraging.

Non-suppurative Conditions.

Rheumatic Group.—Some twenty cases of rheumatic conditions have been examined and treated, and on the whole with very satisfactory results. In these cases again deficiency of ionic calcium was found and the same sequence of events occurred—namely, that improvement commenced when the ionic calcium began to return to normal. Cases may be quoted as typical of some of the results obtained.

Rheumatoid Arthritis.—Mrs. B., aged 45, for years had suffered from Graves's disease and was still not free from general symptoms. For over a year she had had osteo-arthritis and for some months had only been able to leave the house in a bath-chair. Many joints were affected, but especially the wrists, fingers, and knees. For some time there had been a septic focus in the nasal sinuses, from which there had been a discharge into the throat. A vaccine from this focus had kept her from becoming bedridden, but for weeks she had hardly been able to leave a chair. On October 22nd the serum calcium was: Combined calcium 1.6, ionic 7.4—total, 9.0 mg. per cent. Parathyroid treatment commenced. In one week the calcium of the serum had become normal. By November 12th the nasal discharge had greatly lessened, she had been out of doors, and with the aid of a stick had walked a mile; the joints were smaller and without pain, except for some stiffness in the morning. She has gone on consistently well; at the end of January the parathyroid was decreased to gr. 1/10 twice a week, but both pain and discharge retracted. On resuming parathyroid daily these symptoms have abated, so that she can get about comfortably and do her housework.

One case was entirely unsuccessful. It was that of a lady of 77 with a rheumatic history of two years' duration. Three years ago she had had an attack of cholecystitis, but had refused operation. Her present condition is almost wholly limited to the right hip. She had had injections of a *B. coli* vaccine without benefit. Calcium deficiency was present, and parathyroid treatment was tried. After six weeks the serum calcium became normal in amount, but the only improvement in the patient was that she slept better.

One case of true osteo-arthritis was treated, but naturally no improvement was expected to occur in the joints affected.

The case was that of a lady aged 61 with a history of several years' duration; she was absolutely bedridden, and the joints affected were ankylosed with considerable distortion. As her blood became normal the pain decreased, she slept better, and felt generally better than she had done since the commencement of her illness.

Sciatica.—Brief mention may be made of two cases of this complaint, as relief of pain seems to be a characteristic of the effect of parathyroid treatment. Mention of it will be made later in connexion with certain cases of inoperable carcinoma. In those two cases the serum calcium was deficient: (1) Combined calcium 1.2, ionic 9.5—total, 10.7; and (2) combined calcium 1.4, ionic 7.7—total, 9.1 mg. per cent. Sepsis of the teeth was present in each case, and both had been in bed for some time under other treatment; but after a short course of parathyroid treatment they were able to get up.

—So far parathyroid treatment has not been used much in this condition, but the variation of ionic calcium in the serum has been watched. Generally speaking, it can be said that as the patient improves the serum calcium returns to normal; if a relapse occurs, then the calcium becomes more deficient. In a case of this kind, which was being treated with salicylate, the serum calcium values were:

Nov. 12.	Combined calcium	2.2,	ionic	7.4—total	9.6 mg. %
Nov. 17.	"	1.5	"	8.5	" 10.0 "
Nov. 22.	"	0.9	"	9.6	" 10.5 "
Dec. 14.	"	1.6	"	8.6	" 10.2 "

The relapse occurred clinically between the last two dates. In this case the patient was put on parathyroid later, but did not lose all pain in the affected joint till four septic teeth had been removed. In another case parathyroid was given on the first sign of a bruit developing, and although a month elapsed before the serum calcium reached normal, the bruit disappeared, and the patient remains in good health.

Arterio-sclerosis and Raised Blood Pressure.—A small number of cases of this type have been investigated, and encouraging results have been obtained by parathyroid treatment. Deficiency of the ionic calcium of the serum has been generally found.

A clergyman, aged 69, had influenza a year ago accompanied by a foul nasal discharge. Following this he had cardiac dilatation and breathlessness, and in the summer definite anginal attacks developed, which culminated in two bad attacks while he was away for a holiday. He has also had very marked pyorrhoea. He has taken parathyroid since November 11th, and the anginal attacks have never appeared again, though his breathlessness remains unchanged. He finds, however, that his capacity for brain work has improved, so that he can work with more ease than he has done for the last six years.

A lady, aged 50, had a blood pressure of 185 mm. systolic and 125 mm. diastolic, for which obvious cause could not be found. Her serum calcium was deficient, and dental sepsis was suspected. Under parathyroid treatment her gums became definitely sore, but she refused to have any teeth removed. The serum calcium became normal and the pressure fell to 155 mm. systolic and 110 mm. diastolic.

A case of tachycardia in chronic Graves's disease may also be referred to:

Mrs. W., aged 48, has had Graves's disease for many years; tremor is still present, though proptosis and thyroid enlargement are now hardly marked. The pulse is normally 80 to 90, and rather easily upset. Occasional attacks of tachycardia occur with a feeling of . . . though no cause can be ascribed to their occurrence. She had pyorrhoea in four teeth and a deficiency in the ionic calcium of the serum. Three weeks after commencing parathyroid treatment the calcium deficiency was improved, her pulse was much more steady, and in spite of an attack of influenza she has not had an attack of tachycardia for three months, and considers that for years she has not been so well.

Conditions of Uncertain Cause.

In concluding this account of conditions benefited by parathyroid treatment, menorrhagia and prostatic hypertrophy must be mentioned. The former condition is often, but not always, amenable to parathyroid therapy; some six cases have been treated with success.

Prostatic Hypertrophy.—A clergyman, aged 62, in July had acute retention. He had suffered from frequency for some years, so that he had been unable to conduct his services without interruption. His urine was clear on withdrawal until the evening of the second day, when there was some blood present, which increased with each catheterization. He was therefore given a grain of calcium chloride intramuscularly, and within twenty-four hours the sensation of the prostate at the point of the catheter passed had changed from softness to firmness. This suggested a possible calcium deficiency, but at the time it was not possible to examine the blood; he was, however, given parathyroid. The catheter was used for ten days, and after that he steadily improved, so that for some months he has had no undue frequency, his services are not

interrupted, and he seldom gets up more than once in the night. His teeth are very septic, and twice since July he has had an attack of facial erythema, spreading like a subacute erysipelas. In these attacks the ionic calcium of the serum was found to be deficient. He has continued to take parathyroid once or twice a week, and as regards the prostatic symptoms keeps well.

More than a dozen cases have been treated with complete success; two long-standing cases which are possibly carcinomatous have only been partly successful. The following are two interesting cases:

J. C., aged 81, was first catheterized on August 8th with much haemorrhage. He went into hospital and refused operation. He never regained power, and was sent out with a catheter, never passing anything without it. On October 6th the calcium content of the serum showed: Combined calcium 2.4, ionic 6.6—total, 9.0 mg. per cent. Parathyroid treatment was commenced. On October 18th the serum calcium was normal. One or two days immediately previous to this date he had passed a little urine spontaneously. On November 5th he was passing more and more urine with slight pain; the catheter was being used twice a day. He thought he passed about a pint daily without the catheter. He improved steadily, and on December 15th gave up the catheter for good. He has lost the sallow look he had previously, and has regained a healthy colour. He is disturbed once or twice only in the night, and says he is better than he has been for years. He continues to take parathyroid once or twice a week. Three bad teeth remain.

T. G., aged 68, had retention on September 11th and required catheterization for three days. Serum calcium: Combined calcium 2.5, ionic 6.4—total, 8.9 mg. per cent. Given parathyroid gr. 1/10 daily. On September 30th the serum calcium content was: Combined calcium 2.7, ionic 7.3—total, 10.0 mg. per cent. On October 13th he passed urine more easily than for years; frequency usually not more than twice in the night. Serum calcium about the same. By November 3rd the serum calcium was normal. He was looking well and was satisfied with his progress. Later he complained of some fullness and indigestion after meals. His remaining four teeth were removed and the indigestion disappeared. He keeps well and is sometimes not disturbed at night at all.

Finally, a word may be said about carcinoma and the effect of parathyroid treatment. A certain number of inoperable cases of this condition were treated; deficiency of the ionized calcium of the serum was found in almost all cases. But although the administration of parathyroid produced a relatively rapid return of the serum calcium to normal, it did not have any apparent inhibitive action on the malignant growth. In a case of carcinoma of the stomach there was less vomiting, and also a marked diminution of pain, so that it was possible to reduce very considerably the amount of morphine given. In another case there was an increase in weight for two or three weeks, combined with an abatement of symptoms and a feeling of perfect health.

SUMMARY.

Though the cases described are representative of a variety of conditions, it will be noted that they have two common factors: all are due to some chronic toxic state, and all have a deficiency in the ionic calcium of the serum, due perhaps to a combination of calcium and toxin. In the majority of cases it was possible to find a primary septic focus, and sometimes the administration of parathyroid caused a hidden focus to become apparent by increasing the leucocytic reaction to the attacking organism. An examination of the literature tends to establish the proposition that the parathyroid glands have a double function: First, a regulation of calcium metabolism, and secondly, the power to render certain toxic substances harmless. Further, it may be noted that in animals where the parathyroid function has been interfered with, either by removal or ligation of the glands, if tetany does not supervene shortly and so cause death, there is a very strong tendency for the animals to die from an infective process.

It is possible that a somewhat similar sequence of events may arise in the cases described. The continued absorption of toxic substances from some primary septic focus may eventually lead to partial parathyroid insufficiency and a disturbance of calcium metabolism. These two conditions will cause a decrease in the resistance of the tissues, so that they are rendered more liable to a secondary septic process. The locality of the latter lesion will depend on local conditions of nutrition, blood supply, and so forth.

From the clinical observations described, it may be permissible to draw certain conclusions.

1. The ionic calcium of the blood becomes deficient in cases where a chronic toxæmia is present. Such deficiency may be regarded as one of the manifestations of the presence of a chronic toxic state, and is an indication that the septic focus should be carefully sought for and treated where possible.

2. Where there are lesions due to such states, healing does not commence until the ionic calcium of the blood approximates to the normal figure.

3. By parathyroid therapy it is possible to rectify the calcium balance of the blood much more effectively than by the injection of calcium salts.

4. The therapeutic use of parathyroid substance in the cases described is essentially physiological. It does not appear to act specifically against any one organism, nor any one toxin. Its action is to place the tissues of the patient under conditions more suitable for the performance of their normal functions, and for combating the effects of toxic processes.

NOTE (by W. R. G.).—The septic foci believed to be the primary cause of the calcium deficiency have in various diseases been found in a chronic ear discharge, the tonsils, the accessory sinuses of the nose, a chronic appendix, the gall bladder, probably the colon (as evidenced by colitis), possibly the uterine, but most often in the teeth. In this connexion the ulceration of the gums (pyorrhoea) has often been the cause, since the removal of the tooth has materially altered the condition of the disease for the better. When a red oedematous line leading from the ulcerating margin outlining the tooth is found suspicion should be at once aroused. From personal observation in these cases the apex of the tooth has always shown erosion.

CARDIAC DISEASE AND OCCUPATION.

BY

R. O. MOON, M.D. OXON., F.R.C.P.,

SENIOR PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART, LONDON.

ONE of the most important problems which confront the physician in regard to diseases of the heart is to give sound advice as to occupation. In former days the great importance of rest in heart disease was perhaps somewhat indiscriminately and unconditionally emphasized; nowadays it would seem that more stress is laid upon the advisability of exercise. This does not mean, of course, that medicine has swung violently from one extreme to the other of treatment, but that in days gone by physicians in their writings were more particularly concerned with advanced cases of heart disease, for which rest must always be the prime requisite. The increased facilities for discovering cardiac abnormalities have not unaturally led medical men to regard such abnormalities as more serious than often they really are, and consequently to apply to them the same line of treatment which would only be suitable in the case of a quite definite disease.

The profession has been gradually learning that cases with cardiac disability are capable of doing much more work than was formerly supposed; true, there have always been wonderful cases of damaged hearts doing extraordinary things, but no prudent physician would base his advice upon abnormal and exceptional cases.

In the case of any cardiac abnormality what one wants to know is whether the abnormal finding indicates any really serious disability at the moment or in the near future. There are quite a number of hearts which it would be well to regard not as diseased but as handicapped, and in much the same condition as a limb impaired by infantile paralysis which limits but does not prevent one's power of walking; no doubt in the case of infantile paralysis it is easier for the patient to discover unaided what he can and what he cannot do than is at first possible for heart cases. Such cardiac conditions would include not only certain valvular lesions and some arrhythmias, but also many hearts with no physical signs which for want of a better term one might describe as "subnormal hearts," where the functional capacity of the myocardium is less than normal, such cases being formerly described perhaps as weak or flabby hearts. Patients with such hearts insensibly drift into sedentary occupations, which suit them fairly well, and it is only when some sudden and unusual output of energy (as occurred so frequently in the army, when cases of this type were enlisted) is called for that the intrinsic cardiac weakness becomes manifest. Many of these cases, however, need not be confined to sedentary work only: they might be much more active, provided they could take their own time over the work. Many of them can earn as good wages as if they had no disease at all.

In a rough sort of way we may think of any given cardiac lesion as of a static or dynamic type, by which, of course, we

mean that in the one case the condition seems comparatively stationary, while in the other it is likely to progress. Cases which are likely to be of the static kind are usually those due to rheumatism, chorea, or scarlet fever occurring in early life; while those of the progressive type are in the main the cases which originate from arterio-sclerosis, or in which syphilis is admitted as a cause. Clearly very different occupations will be adopted for these two categories of cases, and it is only for the static ones that much activity can be permitted. Contrary to what is generally supposed, aortic regurgitation, when due to rheumatism, in a young adult has one of the best prognoses of all valvular lesions from the point of view of work; the reason why it has had such a bad prognosis in the past is that such cases have not been sufficiently distinguished from those of arterio-sclerotic and syphilitic origin, which certainly furnish the larger number of aortic lesions, and their prognosis is specially bad.

Are there any general principles which can guide us in the selection of work for cardiac cases? As a rule, all kinds of work which involve sudden spurts, although there may be comparatively long intervals of rest, are bad for most cardiac patients; the life of the docker and of the soldier, just to take two types, is liable to periodical rushes with unduly slack intervals, and such occupations should of course be avoided. In selecting an occupation it is specially important to consider whether the hours are regular and the work more or less the same from day to day and hour to hour, while there need be no undue sense of hurry in the doing of it. This question of regularity in work requires quite as much consideration as the number of foot-pounds of energy which the work may require to be put forth. Work which places a fairly heavy strain upon the lower extremities is much more easily tolerated than that in which the main strain falls upon the arms. Most forms of aortic disease, and undoubtedly those of the degenerative type, seem to be very unfavourably affected by any work which involves even a moderate strain upon the arms, such as carpentering, and this is particularly the case where there is any suspicion of angina. It should also be borne in mind that aortic cases, when otherwise doing fairly well, are often liable to transient attacks of giddiness, which should rule out the numerous occupations which necessitate going up ladders or close contact with machinery. It is unfortunate that there seem to be so many occupations in which "heavy lifting," though by no means the essential part of the work, yet is often required incidentally; thus a man is suddenly asked to move a heavy piece of furniture, and it is this which does the damage and not the regular work itself.

Apart from the actual occupation one should further inquire into how great the distance is at which a man lives from his work, for often it is not so much the occupation *per se* which proves too much for him as the long walk to and from it, with, it may be, a heavy uphill grind at the end of the day, or there may be the added excitement and anxiety about catching trains or omnibuses. Then, too, at the end of the day it makes a good deal of difference if a man lives in a two-storied cottage or has to ascend to the top floor of some model dwelling. In the case of women, the vast majority even nowadays are occupied in some way with a home, the complicated activities of which are not easy to curtail; often, however, the omission of one single item of household labour, such as "washing," may make all the difference to a woman being able to carry on or having to give up her work. Women as a rule are not good organizers of their own work, but the task is difficult, and they might say with Frau von Stein in a letter to Goethe, "It is not perceived that to discharge the thousand little details of life which we have to attend to more ability (for which we get no credit) is required than for the doings of a genius who is at once accorded honour and fame."

As will be gathered from what has been said, it is a great mistake to suppose that cardiac cases can only do sedentary work; many more active forms of work are open to them, but they require selecting and being carefully gone into. Clearly the most important thing to do is to make some attempt to estimate the power of the myocardium. The significance of the myocardium in the estimate of the seriousness of any cardiac lesion was recognized as far back as the time of Stokes of Dublin, who said:

"It is in the vital and anatomical condition of the muscular fibres that we find the way to cardiac pathology; for, no matter what the affection may be, its symptoms mainly depend on the strength or the weakness, the irritability or the paralysis, the anatomical health or disease, of the cardiac muscles."

Such, too, has been the teaching in the medical schools for the last thirty years, but it has certainly been more emphasized during the last few years by Sir James Mackenzie and Sir Thomas Lewis. Yet with the more generally diffused recognition of the importance of the myocardium one cannot say that our ability to appraise the strength of the heart muscle has increased in the same ratio; still, by a careful inquiry into the patient's symptoms and study of the reaction to exercise an approximate estimate of its power can be obtained.

In considering whether a man with a cardiac lesion should remain at his work, one must not take too abstract a view as to how many foot-pounds of energy are required, but how far the work seems to suit the man—how far, if we may so express it, he is psychically attuned to it, for there are many forms of work which might seem intrinsically too heavy, and so they would be for a beginner, yet by long custom and a natural aptitude they have become easy for the particular individual, who has found out how to accomplish a great deal with the minimum amount of exertion; one must, therefore, hesitate long before removing such a case from his work. We must, unfortunately, among other things, distinguish between a man's keenness about his work and his keenness for the wages which his work brings in, for he will continue to work long after he is quite unfitted for it when the wages are particularly good, and it is astonishing how difficult it is to persuade such cases to take on lighter work, with shorter hours, when any sacrifice of wages is involved.

When the question arises as to the future occupation of a boy with valvular disease, which in early life is usually of rheumatic origin, it is always advisable to recommend some sedentary or quasi-sedentary work, for one can never be sure that a second attack of rheumatism may not occur quite soon and damage the heart still further; also boys are only too ready to overstrain themselves if the work they have been started upon is at all heavy.

In advising work for any given case much must depend on the man's education, previous training, general mental equipment, and temperament. It is obviously more difficult to find work for the unskilled than for the skilled, as the former requires more actual physical exertion than such cases should be allowed to give. It is of course most important that a man should work well within the limits of his capacity so that there may be a margin of safety. Nor should it be forgotten that mental and emotional stresses in many occupations may cause a cardiac case to break down nearly as often as physical overexertion.

Men suffering from a cardiac lesion who can be up and about are far too readily sent off to some convalescent home in the country, when what is really most required is some suitable occupation near their own home. It is quite possible for hearts to be underworked as well as overworked. Cardiac convalescent homes should be primarily for women and children, while for men training centres for occupation with an occupational bureau are indicated, such as have been started in the United States by the Association for the Prevention and Relief of Heart Disease.

FURTHER RESEARCHES ON DETOXICATED VACCINES.

CLINICAL PATHOLOGIST, ST. PAUL'S HOSPITAL, LONDON.

Preliminary Note.

In an article upon the biochemistry of germs and other proteins by one of us (D. T., *Lancet*, i, 1921, p. 849) it was pointed out that all germs could be split up into several non-toxic yet antigenic fractions, and it appeared that a detoxicated vaccine composed of all the non-poisonous fractions was better than one which contained a single fraction only, as was the case with the earliest detoxicated vaccines.

During the past year researches which have been successful have been made with the object of producing more efficient detoxication. Twelve months ago the average dosage of detoxicated vaccines was from 5,000 million to 20,000 million. As a result of more efficient methods of detoxication the

average dosage has been increased at least five times—namely, to 25,000 million to 100,000 million. It seems reasonable to hope that in the near future the detoxication process will be so efficient that doses of one billion germs will be attainable—that is, one million million organisms.

Numbers of this nature convey a very vague impression, but if translated into terms of mass of the semi-solid wet germ substance the actual dose is better appreciated. One million million germs represents roughly a mass of one cubic centimetre of the semi-solid wet bacteria. One hundred thousand million represents, therefore, one-tenth of this value—namely, 1/10 c.cm. of the semi-solid wet germs. Ten thousand million is equal to 1/100 c.cm. of the substance, one thousand million equals 1/1,000 c.cm., and one hundred million equals a dose of 1/10,000 c.cm. These figures vary according to the size of the germ and are only approximate. They are, however, sufficiently correct to convey to the mind a fairly clear idea of the actual doses of germ substance which are represented by hundreds and thousands of millions.

The dose of the ordinary toxic vaccines which have been in general use for the past ten to twenty years averages from five million to one thousand million germs—that is, from 1/200,000 to 1/1,000 c.cm. of the wet germ substance. Now 1/200,000 of a cubic centimetre is practically invisible, and 1/1,000 of a cubic centimetre is about the size of the head of a small pin.

It has seemed to us that injections of such small doses into a comparatively large animal like a man could only produce an infinitesimal amount of antiserum or immunity. The maximum doses of the first detoxicated vaccines—namely, 10,000 to 20,000 million—represent 1/100 to 1/50 c.cm. of the wet germ mass. This is still in reality a very small dose. The dose attained by more efficient detoxication—namely, 100,000 million—represents 1/10 of a cubic centimetre, and the mind begins to appreciate that a dose of this size may conceivably stimulate the formation of a considerable quantity of antiserum producing immunity, and experiments detailed below prove that this is the case.

It is our ambition, however, to reach such an efficiency of detoxication that doses of one billion germs, or 1 c.cm. of the wet germ mass, may be inoculated at a time. There can be little doubt that when such doses are attained the immunity produced will be so great as to produce very remarkable curative results. In the domain of preventive medicine, by such massive inoculations we may hope to be able to guarantee a complete and certain immunity from a given disease for a very considerable period of time.

The Importance of Dose in the Production of Antisubstances or Immunity.

The following experiments were carried out in order to prove the great importance of dosage in the stimulation of antisubstances to any foreign protein. Germs are composed of protein material, and it should be remembered that it is a well-proved law that when any highly complex foreign protein is injected into a living animal that animal has the power of developing a contrary substance, or, in other words, immunity to that foreign protein material. The animals used in these experiments were rabbits, and the foreign protein employed was sheep red corpuscles. Sheep red cells are non-toxic in nature, and very large doses can be injected without making the animals suffer in any way.

If we take the serum of an ordinary normal rabbit and mix it with sheep red cells the serum as a rule exerts no solvent or haemolytic action on these foreign cells. If, however, we inject that rabbit with large doses of sheep cells—namely, a total of 5 c.cm. of the semi-solid wet sheep cells—then the rabbit forms a large quantity of antibody (haemolysin) towards the foreign corpuscles. Indeed, the inoculated rabbit becomes so surcharged with the haemolysin that its serum becomes in many instances capable of dissolving the sheep cells, even when it (the serum) is diluted 10,000 to 20,000 times with normal saline. The smaller and smaller the doses of sheep cells injected, however, the smaller and smaller is the amount of haemolysin produced. This is well proved in the following experiments:

Rabbit A was injected with doses of sheep cells corresponding in mass to the doses of ordinary toxic vaccines given to a man. The mass of toxic germs given to a man, as already stated, amounts to 1/200,000 c.cm. to 1/1,000 c.cm. A rabbit, however, is on the average at least twenty times smaller than a man, so corresponding doses of sheep cells would be 1/4,000,000 to 1/20,000 c.cm. of the semi-solid wet cells. Doses of this size, however, were apparently too minute to stimulate the formation of any appreciable or detectable amount of haemolysin. The haemolytic titre of this rabbit's serum

was tested against sheep cells every few days after each inoculation, but the result was more or less negative.

Rabbit B was injected with doses of sheep cells corresponding in mass to doses of detoxicated vaccine varying from 1,000 to 100,000 million germs—that is, doses of 120,000 to 1200 c.c.m. There was no appreciable rise in the haemolytic titre of this rabbit's serum until doses of 1,400 c.c.m., corresponding in mass to 50,000 million germs, had been given. With doses comparable in volume to 50,000 million germs and upwards in a man the haemolytic titre, however, rose in a very remarkable degree, so that the serum became potent even in a dilution of 1 in 100.

Rabbit C was inoculated with doses of sheep corpuscles corresponding to doses of 1,000,000 million (one billion) germs, or 1 c.c.m. of the semi-solid wet germ substance aimed at in a man. (The rabbit being one-twentieth the weight of a man received actually 120 c.c.m. doses of the semi-solid moist sheep cells.)

Each dose of this size produced a very marked rise in the haemolytic titre of the rabbit's serum, and after seven such doses the eventual immune power of this rabbit rose to the extent that its serum was capable of dissolving the sheep cells when it was diluted 1 in 480 parts with normal saline. In order to get much higher immunity in rabbits wherein the serum is haemolytic to sheep cells at a dilution of 1 in 10,000 to 1 in 20,000, it is necessary to inject cubic centimetre doses of the sheep corpuscles.

It is logical to assume from these experiments that, in order to obtain a similar highly potent antiserum in man towards bacteria, similar massive doses of germ substance must be injected. Furthermore, for successful immunity it is not necessary to get severe toxic reactions, as many imagine. Sheep corpuscles are very non-toxic. They are hundreds of times less toxic than the most efficient detoxicated vaccines ever produced. The inoculations which were given to the above rabbits produced no toxic reactions whatsoever, yet the graphs of Rabbits B and C showed an enormous immunity response.

With regard to vaccine therapy there is still another fallacy or heresy which is frequently preached—namely, that if one injects too much vaccine the system becomes tired and overworked so that it can produce no more antibody. If a rabbit can keep on producing antibody to doses of sheep cells totalling 5 c.c.m. of the solid moist corpuscles, surely doses of germ substance amounting to a minute fraction of a cubic centimetre will not exhaust the immunity-producing powers of a man who is enormously greater in weight and size than a rabbit.

It would seem more near the truth to say that it is the toxins of the germs which tire and exhaust the system. These toxins require to be removed, so that enormous doses of the germ substance proper may be given. We wish to develop in our serum a quality which will destroy germs by dissolving or lysing them. Such an immune serum would be a much more valuable possession than a serum which simply neutralized the poison of the germs. In any case it is stated in practically every modern work on immunity that it is very doubtful if antisubstances can be produced against the endotoxins of germs. These endotoxins are allied to the amino-acid derivatives of proteins, and it is known that no antisubstances are formed against such simple derivatives. Again, even if antisubstances can be formed against them, they are too toxic to permit of large enough doses to obtain any appreciable amount of such an antisubstance. Against certain toxins it is true that good immunity is produced—for example, against diphtheria and tetanus toxins. These toxins, however, are highly complex protein substances, allied to snake venoms, and are quite different from the usual simple endotoxins of germs.

It is stated that antimeningococcal serum is an anti-endotoxic serum, but this perhaps is not quite correct. The so-called meningococcal endotoxin which is injected into horses to obtain this antiserum is a watery extract of meningococci, and is likely to contain much non-toxic meningococcal protein, such as proteoses, etc., as well as the true endotoxin. In the serum of the injected horses, therefore, there will be developed a considerable amount of antisubstance to the protein material of the meningococcus, and this may account for its successful therapeutic results when injected into human beings suffering from this disease.

Improved Detoxication Process whereby Doses of 100,000 million Germs may be given.

About eight months ago it was discovered that in the first stage of the detoxication process—namely, the solution of the germs in NaOH—some of the germs invariably escaped the solvent action of the alkali, and that when acid was added, a certain number of unautolysed germs were carried down in

the precipitate of germ metaprotein. In other words, the non-toxic precipitates of the germ substance contained a small proportion of the unaltered toxic germs themselves. The presence of these unchanged toxic bacteria, though few in number, was nevertheless responsible for a large amount of the toxic action residing in the so-called detoxicated vaccines. In other words, the detoxicated vaccines of a year ago were really a mixture of the non-toxic fractions along with a small proportion of the unchanged toxic germs.

This defect has now been avoided by passing the solutions of each germ fraction through a Chamberland filter before precipitating them. The precipitates obtained in this way after porcelain filtration were found to be about ten times less toxic than before. This filtration process alone, therefore, has brought about a tenfold increase in the dosage of the detoxicated vaccines.

This success, as already stated, leads one to hope that still more efficient detoxication will be attained whereby the ultimate aim of giving 1 c.c.m. doses of the semi-solid wet-germ protein will be reached. The rabbit experiments described lead one to hope that such massive doses will confer on man an extraordinarily powerful immunity, and that they will exert a very efficient curative action on various diseases.

Machine for Crushing Germs.

In order to remove the poisons which reside within the bodies of germs, the latter must be entirely disintegrated or autolyzed. For this disintegration of the bacteria we have up to the present relied entirely upon the dissolving or disintegrating action of chemicals, such as weak alkalis, acids, alcohol, etc. Where weak chemicals are used the protein substances of the germs are not so injured or changed as to effect their specific immunizing properties. For example, it has been demonstrated by Balls and Korns (1918) that if red cells are dissolved in weak NaOH and the protein substance is then precipitated with weak HCl, this protein precipitate when injected into rabbits has still the power of causing the formation of specific haemolysins in the latter. Similarly it has been shown by Kolmer (1917) that specific immunity is produced against certain tissue cells when animals are inoculated with the metaprotein of these cells treated in this manner.

It so happens, however, that certain germs require very strong alkali, and even antiformin, to dissolve or disintegrate them, and such powerful chemicals are likely to have a deleterious effect upon the specific antigenic properties of the germ proteins. For this reason during the past two years strenuous endeavours have been made to find some mechanical means of disintegrating germs, in order, so far as possible, to avoid the use of strong chemicals in the detoxication process. Several machines were devised and constructed for this purpose with varying degrees of success. A machine was devised recently by Plauson which was claimed to have the power of smashing substances into colloidal form. Through the courtesy of Messrs. Plausons, Ltd., the disintegrating effect of this machine on germs has been tested. Emulsions of yeast and staphylococci were subjected to the smashing effect of the machine for thirty minutes, and they came through the test unaffected. It is the insignificance of germs which saves them, since they measure about 130,000 to 150,000 of an inch in diameter.

With the aid of a designing engineer, Mr. Macfie, one of us has been able to construct a small machine which has a cutting as well as a grinding action. It is capable of giving from 5 to 20 million cuts in the emulsion a minute. This machine, in the first few tests made, appears to be more efficient than the Plauson smasher, and it has enabled the writers to employ much weaker chemicals in dissolving the germs than hitherto used. With the present design, however, it is still incapable of smashing the germs in water—that is, without the aid of some chemical. When very fine carborundum powder, however, is added to the watery germ emulsion and the mixture smashed in the machine the disintegrating effect on yeasts or germs was very considerable without the aid of any chemicals at all. There is no doubt that this machine should mark a very considerable advance in the detoxication process, and much better vaccines will be obtained by its use. It has been returned to the maker for some alterations in design which are calculated to make it more efficient, and it is hoped that the end in view—namely, the disintegration of germ emulsions with very weak chemicals or even without them—will very shortly be attained.

The authors wish to express their thanks to Mr. E. S. Dean and Mr. F. T. Downing, who have been associated with them in this research.

STRANGULATED DIRECT INGUINAL HERNIA.

BY

E. E. HUGHES, CH.M.MANCH., F.R.C.S.ENG.,

HONORARY SURGEON, ANCOATS HOSPITAL, MANCHESTER; VISITING SURGEON, MANCHESTER CHILDREN'S HOSPITAL.

THE formation of a direct inguinal hernia is due, in the majority of cases, to repeated distension of a weak point in the posterior wall of the inguinal canal. In such cases the abnormal opening in the abdominal wall is usually large, and the edges of the opening offer little resistance to the protrusion of bowel or omentum within the hernial sac. Occasionally, however, when the intra-abdominal pressure is suddenly increased, the weak point in the posterior wall of the inguinal canal undergoes instant rupture, and it is in these cases that strangulation is apt to occur.

In the case to be described the strangulation was probably caused simultaneously with the origin of the hernia—that is to say, a split occurred in the medial portion of the posterior wall of the inguinal canal (conjoined tendon) which allowed of the protrusion of a knuckle of gut—covered, of course, by a layer of parietal peritoneum—into the inguinal canal. The tension of the conjoined tendon tended to approximate the edges of the split and thus prevented the reduction of the hernia and also imperilled the blood supply of the herniated gut, producing its strangulation. Strangulation of a direct inguinal hernia is an event of somewhat uncommon occurrence, and the following case, which was recently under my care, may be regarded as a fairly typical example of this condition.

The patient, a carter, aged 62, was admitted as an urgency case under my care at the Ancoats Hospital, complaining of a painful swelling in the right groin. He stated that, about eight hours previously, whilst loading a cart, he felt a sudden pain in the lower part of his abdomen. At first he endeavoured to disregard the pain, but as it did not disappear he left his work and returned home. Here he noticed a swelling in the right groin, and on going to his doctor was advised to seek treatment immediately at Ancoats Hospital. He gave a previous history of a hernia which was easily reducible, on the left side, but he was quite sure there had never been one on the right side.

On examination the patient was a fairly muscular man, but looked decidedly ill. Over the inner third of Poupart's ligament on the right side there was a rounded tender swelling, tense, elastic, quite free above and below, and apparently not communicating with the internal abdominal ring. There was no impulse on coughing, and gentle taxis failed to have any effect on its reduction.

On the left side there was an easily reducible direct inguinal hernia. Operation was immediately carried out. The inguinal canal was opened by division of skin and external oblique aponeurosis. The hernial sac at once presented itself, and on isolation was found to be entirely free from, and external to, the spermatic cord. The neck of the sac was traced to the conjoined tendon. The sac, which was extremely thin, was then opened. A quantity of the usual blood-stained peritoneal fluid escaped, and a knuckle of bowel of the Richter type, and plum-coloured, was seen. Digital examination of the neck of the sac from within showed that the constriction was due to tension of the conjoined tendon. A hernia director was passed within the sac, and the tendon was divided in a medial direction. The gut was drawn out of the abdominal cavity, found to be viable, and then reduced. An attempt at a radical cure for the hernia was made by ligaturing the sac, suturing the split in the conjoined tendon, and then suturing the internal oblique muscle to Poupart's ligament.

The patient made an uninterrupted recovery, and was discharged from hospital seventeen days after admission.

THE Fifth Italian Congress for Industrial Diseases will be held at Florence from June 11th to 14th, when the following subjects will be discussed: (1) Rural hygiene since the war, especially in relation to malaria, introduced by Professor A. Monti; (2) new and old views on lead poisoning, introduced by Professor C. Biondi; (3) reform of legislation relating to industrial accidents, introduced by Professor Borri; (4) prevention of disabilities following disease, introduced by Professor L. Devoto. An exhibition will be held illustrating the most recent methods for preventing industrial accidents.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TUBERCULOUS PERICARDITIS.

MEDICAL literature contains so few references to tuberculous pericarditis that I feel justified in recording the case mentioned below as being of interest.

A student, aged 23, who had arrived in England for the first time eighteen months previously from a colony, was admitted to the hospital of SS. John and Elizabeth on April 13th, 1921, with a history of having taken to bed for a week with marked malaise and rise of temperature. There were no other symptoms whatever. He had always enjoyed excellent health, and had never suffered from any pulmonary complaint. On admission his temperature was 103.6° F., pulse rate 120, and respiration rate 40. He was tall, thin, and of a pallid complexion. His breathing, though rapid, was unembarrassed. The tongue was clean.

On examination the right side of the chest was almost motionless and dull from the fourth rib downwards, where vocal fremitus was almost absent. Breath sounds were prolonged and high-pitched above and practically absent below the fourth rib. The apex beat of the heart was displaced to the left, and an exocardial to-and-fro murmur was heard. Aspiration of the right chest yielded 20 ounces of clear fluid, which on microscopic examination showed neither cells nor bacilli, and on culture this remained sterile. A diagnosis of pleural and pulmonary tuberculosis was made.

The murmur at the cardiac apex became more marked as time progressed, and seemed rougher and louder on expiration, and on May 19th some fine crepitations were heard in the right mid-axillary line, both on inspiration and expiration. These extended anteriorly on the 31st, when a very marked rough creaking pleural rub was also heard over the left base anteriorly. Night sweats at this date became very marked. Repeated examination of the sputum revealed no tubercle bacilli. The cardiac area of dullness appeared to increase gradually to the left and right, and on June 6th the exocardial murmur, which had been getting less audible, disappeared, and at the same time the heart sounds became less distinct. Breath sounds in the left mammary region were now harsh, and in the right scapular region almost tubular in character and accompanied by fine crepitations. Emaciation became more marked. Tuberculous pericarditis was now diagnosed.

X-ray examination on June 16th showed an enormous cardiac shadow, and loss of pulsation; this was suggestive of pericardial effusion. Paracentesis pericardii was performed on three occasions with obvious relief to the patient. The fluid obtained, altogether 8 ounces, was sanious in character, and sterile in direct films and culture. No tubercle bacilli were detected. The right base was also aspirated and a similar fluid obtained, which was shown to be sterile bacteriologically. The patient died on July 1st. During his illness the temperature was continued for the first ten days; subsequently it was intermittent, ranging between 97° and 102° F.; the pulse rate varied between 90 and 140, respirations from 18 to 35.

Post-mortem Examination.—The body showed extreme wasting. On opening the chest the parietal pericardium was found to be very thickened, in parts up to a quarter of an inch, and was fused with the thickened visceral pleura. The visceral pericardium was markedly thickened by a deposit of caseous material to the extent of half an inch. The pericardial cavity was dilated and contained approximately 8 ounces of sanious fluid. The heart muscle was very pale and flabby; the valves were competent. The pleurae were thickened and contained some free fluid; and the lungs, which were adherent to these in parts, especially on the left, showed numerous miliary tubercles, but practically no evidence of old tuberculosis. The mediastinal glands showed moderate enlargement. The liver, spleen, and kidneys showed amyloid degeneration; the latter had a few miliary tubercles, and the peritoneum was studded with these. Free fluid was present.

For kind permission to publish this case I am greatly indebted to Dr. A. Saunders, Physician to the Hospital of SS. John and Elizabeth.

F. JOSELIN JAUCH, M.R.C.S.Eng., L.R.C.P.Lond.,
Resident Medical Officer, Hospital of SS. John and Elizabeth, London.

RUPTURED HEART.

THE following case seems to me of sufficient interest to place on record, as it illustrates how a fatal result may follow a very slight effort in a person who was not apparently seriously ill, her chief complaint being of shortness of breath.

On January 10th, 1922, I was called hastily and found a fairly well nourished woman lying on her back on a bed. She was quite dead. The only person in the house besides the dead woman was her husband. He said his wife was about 50 years of age, was almost a teetotaler, and had never been really ill before, but a few months ago had had an upset and had lately complained of shortness of breath. On this particular day, not feeling very well, she stayed in bed; during the morning he heard a noise as of someone falling.

went upstairs and found his wife lying on the floor quite motionless. She never moved again. He lifted her on to the bed and sent for me. So far as one could gather from the husband she just got up out of bed and fell down dead.

Post-mortem Examination.—There were no marks of violence or bruising on any part of the body. On raising the sternum the pericardium was found to be full of blood clot and there was a rent in the anterior wall of the left ventricle about three-quarters of an inch long; the heart was enlarged, and there was marked fatty infiltration of the organ; there was also some thickening of the aortic valves.

J. ANGELL JAMES.

Reports of Societies.

WAR WOUNDS IN RELATION TO LIFE ASSURANCE.

At a meeting of the Assurance Medical Society on May 10th, with the President (Dr. R. A. Younge) in the chair, a discussion took place on "War wounds in relation to life assurance." A similar discussion was held in the society three years ago, when a table was presented by Mr. McAdam Eccles (*Transactions of the Society*, 1919) containing certain suggestions for the acceptance, with or without load, or the rejection of lives damaged in the war.

Mr. McAdam Eccles said that later experience had proved the necessity of very few corrections in that table. He had urged that all cases of penetrating gunshot wounds of the head which gave rise to mental changes or fits should be rejected, but perhaps this was too sweeping a counsel so far as the fits were concerned. It was possible also that some would take exception to his advice that cases in which there had been fracture of the skull, with operation, loss of bony substance, visible pulsation, but no serious symptoms, might be accepted, with a debt, according to the nature of the case. Quite a number of such cases had now had the gap in the bone filled up by bone taken from elsewhere in the body, and some of the patients had been completely restored to their normal, with no headache, fits, or obsessions of danger, and no want of concentration. He would be inclined to accept such cases at ordinary rates if they had had three years of good health from the time of the operation. In fractures of the base of the skull, the result of aeroplane accidents, there were cases in which the proposer had apparently suffered little permanent damage as a result of the injury, and some of these cases might be accepted at small load, or even at ordinary rates. He adhered to his original recommendations with regard to gunshot wounds of the neck, that when there was no permanent disability the case should be accepted at ordinary rates, when there was need for a tracheotomy tube the case should be rejected, and when there was slight damage to larynx or injury to the large vessels or nerves there should be a load of three to five years; he would add, however, that in this last category care should be taken that there were no resulting symptoms of the injury, such as a traumatic aneurysm, which might give rise to an embolism, causing hemiplegia. In his original suggestions with regard to injuries to the abdomen he had omitted those cases in which the spleen had been removed for injury; many of these recovered entirely, and if there was not a definite history of removal of the spleen it would be difficult to tell that the organ was missing. The proposers might be accepted at ordinary rates three years after complete recovery, but in any case where examination of the blood showed a want of return to the normal a load of five years, or even rejection, must be advised. He also raised the question of cases in which there had been amputation of both upper or both lower extremities—whether these should be accepted, and, if so, at what load. In conclusion, he reminded the society that all the men concerned had served their country well, and should have every consideration when they presented themselves for assurance.

Mr. G. E. GASK dealt with war wounds of the chest and their prognosis in relation to life assurance. He thought that wounds of the parietes without injury to the internal viscera need not be considered as having impaired the life; also that the vast majority of men who had suffered from perforating wounds of the chest unaccompanied by retention of a missile or the formation of an empyema were now completely cured and might be considered as sound lives; but that men who developed an empyema following a wound of the chest ran a grave risk, and he thought the actual damage

comparable to that resulting from an empyema which followed an attack of pneumonia. In assessing their life value it must be remembered that they had successfully passed through a severe illness, and that the efficiency of one lung might have been permanently impaired. Perforating wounds associated with a persistent empyema-sinus or retention of pus in the chest constituted a grave risk to life, but the number of men now suffering from this condition must be very small. As for retained missiles, a missile which had remained for four or five years embedded in the muscles was not likely to give rise to trouble. A missile lodged in the lung or mediastinum must be considered an added risk to life, and a piece of metal with jagged edges was more dangerous than a smooth bullet.

Dr. ALDREN TURNER spoke of gunshot injuries to the head in relation to epilepsy. There were two groups of epilepsies to be considered: (1) Genuine traumatic epilepsy with definite brain lesions, and (2) the less common group in which epilepsy occurred without obvious injury of the brain. This second group was the more difficult to consider from the point of view of prognosis and treatment, and in war cases from the point of view of attributability. In the first group most of the cases had hemiplegia or some definite evidence of lesion of the central nervous system, and there was no difficulty at all in adjudicating direct attributability in epilepsy of this type. The fact that a man who had had a gunshot injury to his head with brain lesion developed a traumatic epilepsy a few months later was a reason, he thought, for granting the full disability pension irrespective of whether any member of the man's family had had epilepsy. It had been possible to divide a series of cases presented to a medical board into traumatic epilepsy of an idiopathic character and epilepsy of the Jacksonian type. In nine cases out of eleven Jacksonian epilepsy had been cured by operation, which showed that the condition was not epilepsy in the strict acceptance of the word, but a cortical irritation due to a definite lesion. It was held by Sargent that it was due to a vascular change occurring periodically at the seat of injury. In many cases the brain was anchored to the cistern, and a change in the position of the head might lead to an epileptic seizure. Out of 18,000 cases of gunshot injuries to the head under the care of the Ministry of Pensions, only 800 (or 4½ per cent.) had developed traumatic epilepsy, a proportion very similar to that obtaining in the Franco-Prussian war of 1870. The smallness of the relative number suggested that research must be carried further afield, and an attempt made to discover how this epilepsy occurred, and whether there was any hereditary and constitutional disposition. He could not help coming to the conclusion that in this particular form of traumatic idiopathic epilepsy following upon gunshot injuries with organic lesion of the brain, the epilepsy was really a symptom of an inherited or inborn neuropathic condition. From the point of view of assurance, these cases ought to be regarded as idiopathic epilepsy was regarded in civil life—namely, as not uninsurable, provided other conditions were normal.

Dr. OTTO MAY asked whether Dr. Turner had had any experience of epilepsy arising after, and possibly caused by, injuries to parts of the body other than the head. In a case of fracture of the leg, when there was no obvious head injury nor any loss of consciousness, the person concerned had his first epileptic fit five months after the accident, and had had five or six since; there was no family history, and the only thing to be detected on examination was a certain tremulousness of the face muscles, which made him think of the possibility of a syphilitic condition, precipitated by the shock of the accident.

Dr. OGIER WARD asked what was to be done in cases in which missiles remained in the limbs—embedded in the head of the tibia, for instance, or in the cavity of the long bones. As for the loss of two limbs, it used to be remarked that one never saw a man who had undergone a double amputation survive to old age. That might have been due to the great drain upon his vitality, in pre-septic days, from the shock of the operation. There was still shock under anaesthesia, though, of course, the patient did not feel it, and it was a question how far it reacted on the constitution.

Dr. A. CHARLES GRAY asked whether a man who had lost one or both lower extremities should be definitely loaded, and whether there was increased risk of accident or of ill health. Dr. H. W. COLLIER gave an interesting account of two cases in which fits occurred after head injuries sustained in aeroplane crashes. The first fit occurred in one case as long as four years, and in the other as long as six years after the

accident. Dr. G. G. Howitt contested Mr. Eccles's advice, in wounds of the head and face, to reject a case in which there had been depressed fracture and no operation. He thought that it all depended upon the position of the depressed fracture. Dr. SANDENSON, of the Ministry of Pensions, said that experience in his department bore out the general reliability of Mr. Eccles's table. Certain researches had been carried out on the after-effects of gunshot wounds of the head, chest, and abdomen, but these were not yet published. Not many cases were available, and it was surprising that the resulting injury seemed to be very much less than might have been anticipated; it was difficult even to secure the men's attendance at hospital. He had found no obvious connexion between gunshot wounds in the chest and liability to tuberculosis.

The PRESIDENT spoke with regard to Mr. Gask's five categories of chest wounds. Cases which had had wounds of the parietes without injury to the internal viscera he would accept without any load at all. Perforating wounds of the chest, without retained missile or formation of empyema, would make him look closely to see what degree of adhesions or limitation of lung movements had occurred, and if there were any such he would be inclined to put on a slight load. The same applied to perforating wounds which were complicated by the formation of an empyema, now soundly healed. He would reject cases of perforating wounds associated with a persistent empyema sinus or retention of pus in the chest; and in cases with retained missile he would be guided by the result of an x-ray examination.

Mr. McADAM ECCLES, in replying on the discussion, agreed with Dr. Aldren Turner that in traumatic (possibly called idiopathic) epilepsy one generally found, on careful investigation, a previous family history, not necessarily of epilepsy, but of some nerve condition, and that the true Jacksonian cases were much better from the point of view of life assurance than the traumatic (idiopathic) ones. In answer to another point, he had not seen a single case of retained foreign body in a lung which had developed tubercle. There were cases of damage to the lung in which tubercle had come on afterwards, but tubercle was such a common disease that it might have developed in any case. He agreed with Dr. Howitt that a case in which there was a depression over the frontal region, particularly the frontal sinus, which led to no symptoms at all, might be taken at ordinary rates; but he was always chary of a depressed fracture. As for the amputation of the lower extremities, any increased risk of accident was counterbalanced by the likelihood that a man who had thus suffered would take extra care; but the important factor was the narrower opportunity of healthy exercise in such cases. The great danger of missiles retained in the limbs arose from sepsis, sometimes arising on the occasion of a trivial operation after everything had been apparently quiescent for years.

"APPENDIX DYSPEPSIA."

At a meeting of the Liverpool Medical Institution held on April 27th, with the President (Dr. J. HILL ANBRAM) in the chair, Dr. R. J. M. BUCHANAN read a paper on appendix dyspepsia. In a brief historical sketch of the development of the diagnosis and the surgery of the appendix Dr. Buchanan referred to the so-called pelvic abscess in women, which was formerly opened by gynaecologists, and was in his opinion appendicular in origin. He referred to the appendix as the mimetic organ of the abdomen, and in this connexion reviewed the literature of early appendicitis and its gradual recognition and separation from the other better-known acute conditions such as perforated peptic ulcer, cholecystitis, volvulus of small intestine, ruptured ovary, the pleurisy, and pneumonia. Proceeding to chronic conditions he showed that the appendix was even more mimetic. Circle to appendicitis and peptic ulcer were closely allied in symptomatology, and operations for peptic ulcer frequently revealed a chronic appendicitis as the cause of the symptoms. Important points in diagnosis he indicated as follows. Remission of symptoms in duodenal ulcer. Radiation of epigastric pain to the lower abdomen suggested appendicitis, as did tenderness over the appendix area. Relief of pain in peptic ulcer by taking food did not hold for cases of appendicitis, and over long periods alteration in free HCl obtained in appendicitis. The dorsal pain of ulcer was rare in appendicitis; alkalis and bismuth rarely gave relief in that condition. There was not the same constancy in appendicitis of pain referred to meals and not the same intensity of pain—merely discomfort. Appendix pain was

increased by exertion, and there was no complete remission of pain or dyspepsia. He referred to a case of chronic appendicitis simulating hour-glass stomach by x-ray examination, but manifesting tenderness over the appendix area. Laparotomy demonstrated an inflamed appendix showing that the x-ray hour-glass appearance was due to reflex spasms. Appendicectomy relieved all symptoms. He suggested that many cases of "ovaritis" in women on the right side were really chronic appendicitis, and he referred to the frequent association of the two conditions and advocated surgically a median incision. In the association of chronic appendicitis with colitis the appendix was often the harbour of infective noxae.

He instanced one case of diarrhoea persisting for many years where Dr. Cronin Lowe obtained an almost pure culture of *Bacillus enteritidis* in the stools. The appendix on removal was found to contain a pure culture of the organism. The operation combined with an autogenous vaccine led to complete recovery and the disappearance of the organism from the stools.

He mentioned the association of chronic appendicitis with distended caecum and a vascular Jackson's membrane and emphasized the importance of combining an appendicectomy with plication of the caecum in these cases. Emphasis was laid upon the importance of realizing that appendix pain was referred to all regions of the abdomen and even down the right thigh, and that retrocaecal inflamed appendices simulated lumbago and cholecystitis.

Dr. Buchanan referred to the x-ray appearance in appendix disease and insisted on the importance of a "watch through" examination, and he was of opinion that sufficient attention was not paid by radiographers in recording the filling, emptying, beading, etc., of the appendix. He advocated a more complete examination at shorter intervals. He thought that an appendix which filled and retained barium or bismuth after the caecum had emptied should be removed. He held that chronic appendicitis should be suspected in any case complaining of chronic and obscure dyspepsia symptoms—for example, pain after food erratic in time, character, intensity, and situation, often referred finally to the right iliac fossa, with nausea, occasional vomiting, illness and feeling of flatulent distension, acidity and water brash, symptoms of general malaise (with or without a history of previous acute abdominal pain), pain and discomfort remittent rather than intermittent, aggravated by exercise and relieved by rest, elicited by rotatory manipulation of the right thigh—in which diet and the usual therapeutic measures did not relieve completely pain which might be elicited by palpation of the appendix and referred to one or other of the regions already mentioned. Such a condition was often associated with irregularity of the bowel, general digestive discomfort and malaise, the x-rays revealing an appendix retaining food (or even failing to show this, for the constriction might be at the opening). A condition of clinical obscurity, not fitting in with any classic syndrome of other abdominal lesions, should always lead one to suspect chronic appendicitis and act accordingly.

Mr. W. THELWALL THOMAS alluded to the frequency of cases of vague abdominal symptoms, described as indigestion, which often could not be definitely referred to the contents of the upper abdomen. X-ray examination in recent years had greatly assisted in clearing up the difficulties as between gall stones, gastric or duodenal ulcer. There remained many cases which could be referred to the appendix, and here radiology in expert and shrewd hands materially helped with the diagnosis. The association of alternate constipation and diarrhoea, accompanied by pains in the right iliac fossa, and referred on pressure to the remote parts of the abdomen, was strong evidence of chronic appendix trouble. He was not prepared to admit haematemesis as a sign, having seen some cases where, after removal of the appendix, the bleeding reappeared. Operative interference was necessary in these cases, and he was gratified to find that physicians were becoming actually enthusiastic in this direction. Where the caecum was dilated and protruded into the pelvis with a well-marked Jackson's membrane, he removed this tissue, infolded the caecum, and fixed in the iliac fossa, with satisfactory results.

Mr. THURSTAN HOLLAND showed a number of lantern slides illustrating the various points of importance in the x-ray examination of the appendix. He emphasized the fact that there was as a rule no difficulty in visualizing the appendix; there was no special hour after taking the meal at which it was most likely to be full of the barium food, but that it might be on view at any time after the food had reached the caecum.

and ascending colon. He also stated that in his experience no special preparation of the barium meal was either necessary or advantageous; he had found that with the ordinary mixture of bread-and-milk and barium, so often used for stomach examination, the appendix was seen just as often as after the much-vaunted buttermilk meal. Of the value of an x-ray examination of the appendix in cases with vague gastric symptoms there could not be any doubt.

Syphilis of the Nervous System.

Dr. BAKER YOUNG read a short paper on syphilis of the nervous system, with special reference to intrathecal therapy, based on the treatment of 109 cases of late syphilis and parasyphilitic conditions of the cerebro-spinal system. The results of the treatment of these cases by intrathecal injection of reinforced salvarsanized serum was demonstrated. The findings of the cerebro-spinal fluid were correlated with the change in clinical symptoms. Dr. Baker Young held that this method of treatment was effective in cases which were not influenced by any other therapy, and emphasized the importance of adopting this treatment in progressive cerebro-spinal syphilis.

Professor W. H. ROBERTS recounted the results of his work on the estimation of the arsenical content of the cerebro-spinal fluid. He had found no trace of arsenic in the fluid after intensive intravenous treatment, but had shown the presence of arsenic in 19 cases out of 29 one week after intrathecal injection. The proportion of arsenic varied from 0.5 to 2 parts per million.

Dr. L. S. ASHCROFT discussed the paper from the pathological side, and supported Dr. Baker Young's views. Dr. A. DOUGLAS BIGLAND criticized the procedure, preferring the older methods of treatment, which were effective and less troublesome. Dr. STOFFORD TAYLOR also favoured the older methods of treatment.

AN ALTERNATIVE METHOD OF ADMINISTERING VACCINES.

At a meeting of the Edinburgh Medico-Chirurgical Society held on May 3rd, Sir ROBERT PHILIP presiding, Mr. DAVID LEES, F.R.C.S., spoke of various methods devised to overcome the toxicity of vaccines in the production of active immunization, and gave an account of his use of Besredka's method in over a hundred cases. These were chiefly cases of infection of the lower genito-urinary tract, gonorrhoeal in nature, including acute conditions as well as subacute and chronic, but comprising also other kinds of general and local infections. The method, as practised by him, was to give a very small preliminary desensitizing dose, about 1,000 to 1/100 of the ordinary dose of the specific organism; this was followed by the immunizing dose, if intramuscular, three to four hours later; if intravenous, ten to twenty minutes later. In most of his cases the immunizing dose was given intravenously, and in the case of gonococci the dose was often 10,000 to 20,000 million. In the gonorrhoeal cases, local treatment of the urethra by weak permanganate solutions was also given, and the usual dietetic and general treatment carried out. The results in a series of cases were detailed, excluding early cases of acute gonorrhoea a few hours after the onset of symptoms, established acute cases, acute complications such as epididymitis and salpingitis, acute *B. coli* infections of the bladder. The standards of cure were absence of clinical symptoms for a long period and negative bacteriological and serological tests. In a certain number of cases this standard was attained, and the immediate effect of relief of symptoms was striking and rapid; in others the result was not so good. He had found the cases most suitable for this treatment were those of early gonorrhoea, within twenty-four hours of the onset of symptoms, and the acute exacerbations of chronic cases; in established cases it certainly lessened the gross signs and symptoms. By this method it was claimed that much more potent doses of vaccine could be given, not only in subacute and chronic infections of the lower genito-urinary tract, but also in acute infections, and this with only minimal reactions, local, focal, and general. As a method of treatment it was still in the experimental stage, and he had not reached a final opinion as to its value.

Plastic Surgery of the Nose.

Dr. DOUGLAS GUTHRIE gave a lantern demonstration on this subject, showing also three patients who had undergone

operation for nasal disfigurement from lupus, congenital syphilis, and injury. The reconstruction of the nose was no modern invention of surgery; for Tngliacozzi, as early as 1570, had perfected the method of transferring a flap from the arm to form a new nose—the so-called Italian method—and this operation was still in vogue. The sacrifice of a finger to gain a nose was also sometimes practised, but was hardly justifiable. These operations had now been largely superseded by the use of local flaps from the forehead, the Indian method of Keegan and other I.M.S. surgeons, and improved by the recent work of Major Gillies. The various stages in a case of nasal reconstruction in a man whose nose had been destroyed in an electrical accident were then shown. It was essential to provide a lining for all flaps to avoid subsequent shrinkage, and support was secured by embedding strips of cartilage in the tissues destined to form the flap. Considerable time should be allowed between the stages of the operation. At times it was advantageous to employ the long tube flap from forehead or neck. Gross defects requiring complete rhinoplasty were less frequent than minor deformities of a part of the nose. Cases belonging to this latter group of lupus, of syphilitic deformity, of a horse-bite of the tip of the nose, and of harelip deformity were shown, and the details of reconstruction described and the results demonstrated by lantern slides.

Therapeutic Value of Quinidine Sulphate in Auricular Fibrillation.

Dr. W. T. RITCHIE briefly alluded to the literature of the subject since the publication of papers by Frey in 1918. In over 200 reported cases of auricular fibrillation restoration of the normal rhythm after use of quinidine sulphate had been claimed in 57 per cent. High claims had been made for the drug, and it was alleged to obviate the necessity of continuing digitalis. He presented a personal study of 12 cases in which quinidine had been tried and its effects observed. Of the 12, eight were men and four women; they included 8 cases of mitral valvular disease (a majority rheumatic), 1 exophthalmic goitre, 1 melancholia, 1 syphilitic myocarditis. The results had been permanent restoration of the normal rhythm in one case; for a considerable period in one; a transient restoration in one. Fibrillation had been replaced by flutter in one case, while the drug had failed to affect the rhythm in eight of the twelve cases. From the point of view of symptoms and general condition only two cases experienced benefit. The usual dosage had been employed, 0.4 gram thrice daily, with an initial smaller dosage. The number of cases was small, but the results were not encouraging and did not support the high claims advanced for the drug. He had failed to get indications as to types of case more suitable than others for quinidine sulphate. But if the drug succeeded in a particular case it would again be successful if auricular fibrillation were resumed. He had met with unpleasant results in its use: it might increase the ventricular rate, and, if so, should be combined with digitalis; it also might set up multiple ventricular extra-systoles; and there was also some danger of embolism from dislodged clot in the auricles. He considered that quinidine should not be used in cases where there were such signs of cardiac failure as dilatation of the heart, dropsy, or cyanosis. The action of quinidine on the heart might be considered, in relation to Lewis's theory of circus action of the auricles in fibrillation, as a lengthening of the refractory period of the auricle; but there was no evidence that it could modify or remove the inflammatory or degenerative changes in the ventricular walls that were present in those cases. The disappointing results of the drug were probably due to the confinement of its influence to the abnormal auricular function.

Dr. D. MURRAY LYON confirmed these observations from his experience of quinidine sulphate in seven cases. When given without digitalis it seemed to have a toxic action on the ventricle, and it was advisable to employ digitalis before it or along with it. It was not a safe drug to use unless its effects were carefully controlled by the electro-cardiograph or the polygraph.

A CONGRESS for the sanitary reorganization of Spain will be held at Madrid in June, 1923. The president of the executive committee is Dr. Verdes Montenegro.

A CONGRESS of French-speaking dermatologists and syphilologists will be held in Paris from June 6th to 8th, at the St. Louis Hospital, under the auspices of the French Dermatological Society. Arrangements are being made by Dr. Hudelo, 8, Rue d'Alger, Paris.

Reviews.

BLOOD TRANSFUSION.

THE book by Dr. GEOFFREY KEYNES on *Blood Transfusion*¹ will be welcomed by many. Before the war the transfusion of blood was rarely practised in this country, partly because there was no simple and reliable technique, and partly because serious consequences had been known to follow the operation. During the war the advantages of blood transfusion became so apparent that many new methods were introduced, but none of the earlier methods came into general use because they were too elaborate. Far more work had been done in America than in this country on this subject, so that when the American doctors arrived in the Expeditionary Force they brought information and experience of the utmost value. It was seen that the harmful results of some of the earlier transfusions were attributable to the neglect to ensure the compatibility of the blood of the donor with that of the recipient, and the dissemination of information on this point led to the systematic testing of the donor's blood on the basis of the work carried out by Jansky in 1907 and Moss in 1910. The simplified technique for this investigation which the Americans brought with them rendered it possible for it to be done as a matter of routine. But of greater importance still was the painstaking work of Oswald Robertson, to whom Geoffrey Keynes pays a fitting tribute when he writes, "to him a very large number of men indirectly owe their lives." Robertson's citrate method of indirect transfusion so simplified the whole procedure that blood transfusion was adopted almost universally in the army as the natural treatment for haemorrhage and shock, and during the last year of the war blood was even given under the primitive conditions existing in field ambulances and first-aid posts. Since the war the operation has been applied in the treatment of many of the haemorrhagic diseases with strikingly good results, whilst it is, of course, the recognized procedure of choice in cases of haemorrhage and shock met with in civilian surgical practice. The general public has become familiar with the idea, thanks to the sensational headlines frequently appearing in the press and the records of the "heroic sacrifices" of that seemingly ever-ready donor, the policeman!

There are two classes of medical men who will find the present book extremely useful. As is apt to happen with all new methods of treatment, blood transfusion has been credited with revitalizing power in all the diseases to which flesh is heir, but in this book the medical practitioner will find an account of the various conditions in which blood transfusion will do good and the indications for its administration. Those also who wish to learn a good way of giving blood will find here a satisfactory method of performing the transfusion, together with information as to the attendant dangers and instruction in the testing of the blood group of the donor.

The book commences with an historical review of the subject, in which are recorded many interesting experiments carried out in the seventeenth and eighteenth centuries, in some of which man was transfused with the blood of animals such as lambs. The various medical and surgical indications for transfusion are then presented, and in the following chapter the dangers of blood transfusion are related. A chapter is devoted to the physiology and pathology of the blood groups, and finally the different methods of direct and indirect transfusion are described. No account is given of the method of preserving blood and injecting the washed preserved red cells, a plan that was often of value in the war and which might sometimes find application under peace-time conditions.

The subject of blood transfusion has hitherto only been dealt with in the medical literature of this country by isolated communications concerning special points. The present book gives a clear account of the whole subject; it is well written and enlivened with many happy quotations, and by accounts of not a few entertaining incidents.

THE FUNCTION OF THE FRONTAL LOBES.

In this book, the English version of which has recently appeared with the title, *The Mechanism of the Brain and the Function of the Frontal Lobes*,² Professor BIANCHI has

¹ *Blood Transfusion*. By Geoffrey Keynes, M.A., M.D. Cantab. Oxford Medical Publications. London: H. Frowde, and Hodder and Stoughton. (Demy 8vo, pp. 166; 13 figures. 8s. 6d. net.)

² *The Mechanism of the Brain*. Translated from the Italian by Professor Leonardo Bianchi. Foreword by James H. Macdonald, M.B., D.S. Surgeon: E. and S. Livingstone. 1922. (Roy. 8vo, pp. 348; 62 figures. 21s. net.)

produced a volume which cannot fail to interest neurologists and psychologists alike. From such a high authority much may be expected, and the reader will not be disappointed, for he will find here not only a full account of the author's own experimental and clinical work on the functions of the frontal lobes, with his conclusions, but in addition a detailed review of the whole subject from both the historical and evolutionary aspects.

Beginning with comparative anatomy and a general survey of the evolution of the nervous system from the lowest to the highest forms, the author leads us on to the more modern discoveries of the localization of function in the cerebral hemispheres, which are considered from the experimental, pathological, and clinical aspects. Flechsig's theories of "associative zones" are strongly criticized, and it is interesting further to note that the author evidently does not agree with Marie's views on the subject of aphasia, but adheres to the more classical opinions.

The second chapter is chiefly concerned with an historical survey of the different theories formulated as to the functions of the frontal lobes. The two next chapters are devoted to the anatomy and physiology of the frontal lobes in different species, and to a defence of the author's method of investigation. Then follows a summary of the author's own experimental work, extending over many years. In the next chapter the effects of electrical stimulation of the frontal lobes are considered, especially in relation to movements of the head, eyes, and ears, and the author advances the hypothesis that such movements of the eyes and pupils are connected with the mechanism of attention. An important anatomical chapter on the associative paths between the frontal lobes and the sensory areas of the cerebral cortex follows; here the author's investigations with regard to paths between the cortex and the optic thalamus and corpus striatum will be followed with interest.

The last three chapters, dealing respectively with intelligence and language, the emotions and sentiments, and consciousness, are perhaps the most important and interesting in the whole book. Bianchi does not attempt to argue in detail the whole subject of aphasia, but contents himself with contrasting the aphasic patient with the patient suffering from disturbances of the functions of the frontal lobes. His opinions on the emotions and sentiments will be read with great interest, for they are not perhaps quite in harmony with the majority of current opinion. The book contains an immense mass of information; it is an admirable summary of the work of many years as well as an excellent presentation of the author's own views. A short explanatory foreword is provided by Professor Lloyd Morgan. In conclusion we must offer our warmest congratulations to the translator, Dr. J. H. Macdonald.

LETHARGIC ENCEPHALITIS.

Few medical subjects in recent times have excited such widespread interest or produced such a flood of literature as lethargic or epidemic encephalitis; and it is fitting and opportune that our knowledge of it should be crystallized in the form of an extensive monograph by an acknowledged authority like Professor ACHARD of the Academy of Medicine of Paris.³ The bibliography supplied at the end of this volume, extending as it does to fifty-five pages, is sufficient evidence of the immense number of contributions, both clinical and pathological, which this disease has provoked during the last four and a half years. We are presented in this volume with an admirable picture of this protean disease, especially rich in the descriptions of its many clinical shapes and symptoms. What we miss most is any considered report on its sequelae, though it must be admitted that this is naturally the most difficult aspect of the subject and one which later years may more easily produce. The careful following up of cases is at the present time the most fruitful field for clinical investigations.

After a short historical introduction there follows a long and interesting chapter on the symptomatology; in this the various disturbances of function which may occur are all separately described in considerable detail. We may perhaps be allowed to object to the statement that "the myoclonic forms are characterized by choreic movements," but apart from a few minor criticisms this chapter forms a most valuable feature of the book. It includes a full description of the various modifications which are found in the cerebrospinal fluid and their diagnostic significance. In the next

³ *L'Encephalite Lethargique*. Par le Professeur Achard. Paris: J. B. Baillière et Fils. 1921. (Demy 8vo, pp. 324; 15 figures. Fr. 16.)

chapter the general clinical aspects and course of the disease are well illustrated by careful descriptions of actual cases. The fourth chapter is devoted to the morbid anatomy and histology, its value being enhanced by a section correlating the situation of the pathological changes with the clinical disturbances of function which are produced. Here perhaps more ground for criticism will be found; thus, can we accept as proved the statement that "myoclonus appears to be explained by changes in the optic thalamus and cerebral peduncles," even when it is qualified by the admission that certain forms of myoclonus must be attributed to a spinal lesion?

The epidemiology and the numerous experimental researches on the nature and propagation of the virus receive somewhat scant consideration in view of the importance of this part of the subject. There is a long and interesting chapter devoted to an elaborate comparison of the symptoms with those of other diseases with which it may be confused, such as influenza, poliomyelitis, sleeping sickness, and many others, but since a separate chapter on diagnosis follows, some repetition is inevitably caused. The section on prognosis is disappointing, for it is especially in regard to the sequelae that more information is most urgently needed. In a short final chapter the various forms of treatment, including that by fixation abscess, are briefly discussed.

The value of this monograph lies chiefly in the careful and indeed admirable clinical pictures of the disease which it provides. It would have gained in interest by the provision of more and better illustrations.

THE VIENNA MEDICAL SCHOOL.

PROFESSOR MAX NEUBURGER in a pleasant monograph¹ has given what one may term an anecdotal history of the Vienna Medical School. There is a short introduction by the Professor, in which he very briefly outlines the history of the school. He alludes especially to the two periods in which Austrian medical science attained its chief distinction—the second half of the eighteenth century and the decades which more immediately followed 1850. With characteristic frankness he describes the intervening period as one of complete stagnation.

The main text of the book is composed of extracts derived from monographs previously published; for example, excellent pen pictures derived from Oslander's reminiscences are given of Johann Boer, Raphael Steidale, and Johann Peter Frank. Students of the history of Continental medicine will find much of interest and of humour in the accounts given. Boer, one of the most famous obstetricians of his time (1800), is painted as a cynic. He ate his food lying on his side because he claimed that so doing helped his digestion, and he showed an even greater appreciation of his own comfort when he gave up teaching because his students were so ungrateful. It is interesting to notice that nearly fifty years before Semmelweis's experiments Boer recommended the use of lime water and naphtha water as a vaginal douche and as a toilet for the examiner's hand.

One of the most interesting chapters deals with Austrian medicine and surgery in 1826, as recorded in Stromeyer's collection of stories of German doctors. There is a full account of the evolution of the teaching of pathological anatomy—a clinic which was founded under Skoda's supervision, and developed to the excellence it afterwards attained by the genius of Skoda's assistant, Rokitsansky. The reader will naturally look for details of Semmelweis's life and work, but he will be disappointed; it would seem that even to-day the achievements of that great man have not received the credit which is their due.

The volume is interesting; it is written in an attractive style, and there are excellent portraits of the more famous leaders of Austrian medical science.

GADFLIES.

DR. WERNER MARCHAND² has performed a service to science by collecting all available information about the Tabanidae (gadflies, clegs, etc.) and publishing a very full summary of it, illustrated by reproductions of the figures from the works of all previous authors.

¹ *Die Wiener Medizinische Schule im 18. und 19. Jahrhundert*. By Dr. M. Neuburger. p. 312; illustrated.
² *Gadflies*. By Werner Marchand, Lecturer, Institute for Medical Research. (Double roy. 16mo, pp. 203; 16 plates.)

The Tabanidae are rather of veterinary than medical importance, though many species occasionally bite man, and two species of *Chrysops* are known to be carriers of the filarial worm *Loa loa* in West Africa. A number of diseases of animals, due to protozoa or worms, are carried by these insects, but do not now concern us. Our knowledge of the early stages and habits of the gadflies is relatively slight. It is also fragmentary and scattered over a large number of periodicals; it is therefore entirely inaccessible to the worker in the tropics who is seldom or never able to consult long series of the less important journals. Nevertheless, it may be noticed with surprise that the early stages of the Tabanidae of Central Africa and the Sudan and of the Philippines are better known, owing to the work of Neave and King and Mitzmain, than those of any part of Europe.

The Tabanidae are all of them large flies, and about two thousand species of the family are known; their distribution is very nearly worldwide. The females in the majority of the genera suck the blood of vertebrata, and are wide-ranging insects of powerful flight. It has even been recorded that certain species fly out to sea to suck the blood of turtles asleep on the surface of the Indian Ocean. The males haunt flowers, and are relatively rare in collections. The egg is laid on leaves of plants overhanging water. The young larva, when it emerges, drops to the surface of the water and swims ashore, to bury itself in mud. Most species spend their entire larval life in wet mud or wet sand at the margin of a pond or stream. Others are found in much drier situations, under turf. The larvae are carnivorous, and in captivity will eat earthworms and the maggots of smaller flies; if food is lacking they become cannibal. They are, for that reason, difficult to breed.

So far as we have been able to judge Dr. Marchand's work has been well done. It appears to be well arranged and to include all, or nearly all, available information. It has a fault common to all collations and summaries—that it does not contain enough of the opinions and personality of its writer.

NOTES ON BOOKS.

THE forty-first volume of the *Transactions of the Edinburgh Obstetrical Society*³ comprises the proceedings of the society during the session 1920-21. The contents of the volume include Dr. William Fordyce's presidential address, in which he gives a review of the advances in gynaecology since the beginning of the nineteenth century, and an article by the late Dr. F. W. N. Hanlinton on his further experiences of "twilight sleep." Dr. Horace R. A. Philp writes on "Obstetric experiences amongst a primitive tribe"; Dr. David Shannon on "Périmetry as an index of treatment in contracted pelvis"; Dr. W. Fordyce and Dr. R. W. Johnstone on "Concealed accidental haemorrhage associated with eclampsia"; Dr. F. J. Browne on "Stillbirth"; and Dr. Samuel J. Cameron on the "Surgical treatment of uterine prolapse." Dr. James Yonng describes an organism obtained from carcinomatous growths. The volume is well printed and illustrated.

The sixth edition of Mr. C. J. S. THOMPSON's *Compendium of the Pharmacopoeias and Formularies*⁴ brings up to date a little book which, within the limits set for it, is very useful indeed. It gives synopses of the pharmacopoeias of Britain (including the Indian and colonial addendum); the United States, Japan, France, Italy, Russia, and nearly all the other European countries, together with unofficial and useful formulae and practical aids to prescribing and dispensing. Notes are included on such subjects as medicated baths, the period of quarantine in infectious diseases, colour tests for alkaloids, bacteriological memoranda, and foreign terms and phrases used in prescriptions. An appendix, in addition to such subjects as modern antiseptic dressings for wounds and National Insurance stock mixtures, includes an epitome of the Dangerous Drugs Act, 1920, and a summary of its regulations applying to medical practitioners.

Mr. REGINALD BENNETT's volume of *Medical and Pharmaceutical Latin*⁵ is now in its third edition. It is intended to facilitate the acquirement of medical Latin by students

³ *The Transactions of the Edinburgh Obstetrical Society*. Vol. xli. Edinburgh: Oliver and Boyd, 1922. (Demy 8vo, pp. xxvii + 133; illustrated.)

⁴ *A Compendium of the Pharmacopoeias and Formularies*. By C. J. S. Thompson, M.B.E. Sixth edition. London: J. B. & Sons, and Danielson Ltd., 1922. (3½ x 6, pp. 353 + 24. 10s. net.)

⁵ *Medical and Pharmaceutical Latin for Students of Medicine and Pharmacy*. By R. R. Bennett, B.Sc. Lond., F.R.C. With an introduction by H. G. Greenish, F.R.C., F.L.S. Third edition. London: J. and A. Churchill, 1922. (Cr. 8vo, pp. xiv + 37. 3s. 6d. net.)

of medicine and pharmacy, and begins with a series of exercises in Latin grammar which, as the examples of the syntax are drawn from phrases commonly used in prescriptions, should be of service to those whose Latin is rusty. Latin-English and English-Latin medical vocabularies and examples of foreign prescriptions are provided, and the author gives a number of typical prescriptions, first in the ordinary abbreviated form, and then in the full Latin and English. The volume should familiarize the student with the correct reading and writing of prescriptions in Latin, which is eminently desirable in these days of well-advertised nostrums with names designed to catch the eye and be retained in the memory of the doctor equally with the man in the street. In the new edition the vocabularies have been revised and some of the sections rearranged in order to make the book more useful to the student.

A HALF-CENTURY OF PUBLIC HEALTH IN NORTH AMERICA.

BY

JOHN C. McVAIL, M.D., LL.D.

I.

THE fiftieth anniversary of the American Public Health Association has been made the occasion of issuing a Jubilee Historical Volume, which opens up the whole subject of public health in America and will be of much value to sanitarians everywhere. The volume contains nineteen contributions, each by an author specially qualified for his task, and it is proposed in this series of articles to notice all the contributions.

ON LONGEVITY.

The founder and first President of the Association was Dr. Stephen Smith, and the first of the nineteen contributions to the Jubilee volume is also by a Dr. Stephen Smith. The question naturally occurs, Was this coincidence of names a mere matter of chance, or was the Stephen Smith, M.D., LL.D., of 1921 any relation—say, son or grandson or nephew—of the Stephen Smith who was president fifty years before? The reply is in the negative. The two men are not related—they are identical, one and the same individual. Next year, 1923, will be the centenary of Dr. Smith, the pioneer of American sanitation, and the warmest congratulations of his brethren in the old country go out to the Nestor of American public health and to the Association of which he is the honoured founder. It must have been very gratifying to the Association that Dr. Smith was able to be present at the Jubilee meeting. Fifty years ago the science of public health was in its infancy in America, and there was no selection of hoary-headed pundits to preside over the now body, so they made choice of an enthusiast in his prime, and time has proved their wisdom.

In his opening article Dr. Stephen Smith very naturally refers to longevity, but while resisting the temptation to profess that there is a secret, he confesses that he has a theory—that, indeed, he adopted the profession of medicine as a preventive of recurrent indigestion, with which he had been troubled; to this he attributes the activities of his middle life and the "comparatively comfortable age" to which he has attained. He also quotes Horace's reply to the same question—*Moderatus in rebus*—but he tells how a recent American authority explained his longevity by saying, "I keep my stomach and brain clean." This last rather agrees with the apocryphal story of the centenarian who, being pestered by the questionings of a food crank as to whether he had not exercised specialism in his diet, replied, "I consult my stomach no more about what I put into it than I consult my portmanteau; and if my insides get into trouble I just stick to my own business and leave them to fight it out among themselves." So much for the secret of longevity. As regards the science, Dr. Smith observes that Owen fixed the normal length of the life of an animal at five times the number of years required to perfect the bones; as in man twenty years are required to complete the process, his normal or potential life should be 100. Dr. Smith holds that this is the birthright of every child born fully developed—a most inspiring doctrine.

It is notably curious that the group of pioneers of the

public health movement in England in the first half of the nineteenth century also, nearly all of them, lived to be old men. The age at death of Sir Edwin Chadwick was 90, of Sir Robert Rawlinson, the engineer, 88, of Dr. Neil Arnott 86, and of Sir John Simon 78. The least long-lived of the group were Dr. Farr, the father of the modern science of vital statistics, who died at the age of 76, and Dr. Southwood Smith, who died at 73. It is said that Farr was disappointed at not having been made Registrar-General when that office fell vacant before he gave up official work. Chadwick, however, lived so long that the Government conferred on him the honour of K.C.B. in 1889, when he was 89 or 90 years of age, and some five and thirty years after his public work had ceased.

EARLY HISTORY OF PUBLIC HEALTH IN NEW YORK.

Some account is next given by Dr. Smith of the sanitary conditions in New York City in 1860-70, in the days when "Boss Tweed" was in full control of the city government; it was to defeat his schemes that a Citizens' Association was formed. The first step was a sanitary inspection of the city, paid for by private contributions. Theoretically, one of the functions of the aldermen of New York at that time was to act as a Board of Health, but when a medical delegation waited on the then mayor with a view to getting the Board called together to take measures against approaching cholera, the mayor replied, "I shall not call the Board, for I consider it more dangerous to the city than cholera." At the same time there was a Health Commission for New York, but its duties were not well defined and its chief official, who was at the head of the street-cleaning department, "had an annual appropriation of nearly one million dollars to expend upon his political followers"; he did appoint some scores of Health Wardens, "who were generally saloon keepers." One of these, being asked how he acted when called to a case of contagious disease, replied that he went to the house and called the people into the street, where he gave his orders, which were to burn sulphur, but that he never himself went into the house.

Under these conditions the Citizens' Association in 1864 asked Dr. Smith and another member to prepare a Public Health bill; in so doing they were guided chiefly by the English sanitary laws, then the most complete in operation. Dr. Smith here strikes a note which is heard in various articles by various authors in the memorial volume—a willing tribute to English precedents and pioneers. That earlier action for the prevention of epidemic disease was taken in England was due to the fact that it was much more thickly populated than America, and its population much more crowded into urban areas, so that the conditions which made sanitation a public necessity prevailed in Britain before they had arisen in the New World. All the same, the frank and repeated acknowledgement of the debt which America owes Britain in this respect is very agreeable, though only what the generosity of American sanitarians had prepared us to expect.

The bill which the Citizens' Association promoted contained an unprecedented proposal—namely, that a health authority, having discovered a nuisance, should have power to secure its abatement without resort to the courts, which were completely under the control of Tweed, of whom at that time there was no hope of getting rid. The bill was defeated, but a campaign of education of the medical profession was begun, and, helped by the fear created in the public mind by threatened cholera, the bill was passed in 1866. In our own country, risk of epidemics has often been a valuable incentive to sanitary legislation, but the Americans were also wise in bringing the whole medical profession into the fighting line. This, it may be remarked, makes an excellent precedent for our own Government, which, before promulgating great health schemes, should always consult the organized representatives of medicine. Under the new law a Health Board was set up in New York; its active work for the prevention of cholera had excellent results, and during the past half-century the Health Department, though under the administration of officials of widely different political faiths, has steadily increased in popularity. "The great achievements of the Board," Dr. Smith says, "were the under-drainage of the soil, which prevented stagnant water and relieved the city of malaria; the removal of the cellar population to homes in the open air and sunlight; the removal of offensive industries from residential districts to the rivers; and the enforcement of rigid sanitary regulations." In the last section of his address Dr. Smith advocates the formation of an inter-

¹ *A Half-Century of Public Health. Jubilee Historical Volume of the American Public Health Association. Edited by M. P. Ravenel, M.D. New York: American Public Health Association. (Sup. roy. 8vo. pp. 451. Cloth, 5.25 dols.; stiff paper covers, 3.75 dols.)*

national public health league and concludes a charming article in the following words:

"May I be permitted reverently to suggest that our purpose is the same as was heard by the shepherds on the plains of Judea at the Nativity? Then the quotation 'Goodwill to men' was announced to be the salvation of the soul from sin by Divine appointment; while now we learn that salvation from the sins of the body must be effected by man himself, who created them. Let us apply ourselves to the task with renewed vigour, and thus enable those who will greet the centennial anniversary of this Association to hear from sanitary officials the good news that the death rate of the year 1921 is limited to those afflicted with old age, or to disease or accidents unpreventable and incurable by any agencies known to science."

THE STORY OF THE PUBLIC HEALTH ASSOCIATION.

The second article is the address delivered at the fiftieth anniversary celebration meeting by the president, Dr. Mazzyk P. Ravenel, Professor of Preventive Medicine in the University of Missouri, who has edited the volume. The subject is "The American Public Health Association—Past, Present, and Future"; and what may be called its text is a quotation from Osler:

"Of the altruistic instincts veneration is not the most highly developed at the present day; but I hold strongly with the statement that it is a sign of a dry age when the great men of the past are held in light esteem."

Emphasis is laid by Dr. Ravenel on the fortunate coincidence of the early days of the Association with the work of Pasteur and his followers—Lister, Koch, Loeffler, Sternberg, and others.

Before 1872 only three of the States of the Union had established a Board of Health, though many of the cities seem to have been more advanced, 134 of them having some health organization by the following year. It is rather surprising to read that down to 1872 only two States could claim to have approximately accurate records of births, deaths, and marriages. About American pioneers and progress much of historical value is recorded. In 1879 Congress created a National as distinguished from a State Board of Health, but four years later it was allowed to pass out of existence. The sphere of the Association's work was extended to Canada in 1884, to Mexico in 1889, and to the Republic of Cuba in 1902, so that practically the whole of North America is included, and the members now number 5,000. It is pointed out, however, that (just as in this country) specialization in particular directions is apt to result in the formation of new groups, to the loss of the parent body, though "the platform of the Association is, in length, breadth, and thickness, sufficient to accommodate all who are interested in human conservation." The Association's ambitions include the affiliation of State and county societies with the National parent organization, and that all should be kept in touch with each other through the medium of a great public health magazine.

The Association publishes a monthly journal (*The American Journal of Public Health*), and also a Monthly News Letter. It has for many years striven for the adoption of uniform practices and standard methods for the examination of milk, of air, and the pasteurization of milk, and for a Model Health Code for cities. The address, which concludes with biographical sketches of some twenty of the Presidents of the Association, affords convincing evidence that it has been and is doing admirable public health work in many directions.

CANADA.

The third contribution to the Jubilee volume—the story of public health in Canada—is by Dr. Peter H. Bryce of Ottawa, who has had a large official share in the public health government of the great Dominion. He tells how in the days of French colonization the sale of spirits to the Indians was prohibited, and how, after Britain took possession, a quarantine Act against plague and other such diseases was passed for Lower Canada in 1795; the penalty on the captain of a ship for neglect of quarantine was death, without the benefit of clergy. This was almost as Draconian as the ancient method in Aberdeen, where, as recorded by Dr. Charles Creighton, the magistrates in 1585 erected three gibbets, "one at the merest cross, one other at the brig of Dec, and the third at the haven mouth, that in case any infective person arrive or repair by sea or land to this burgh, or in case any indweller of this burgh receive, house, or harbour, or give meat or drink to the infective person or persons, the man be hanged and the woman drowned." After recording the introduction of vaccination, Dr. Bryce goes on to say that so early as 1816 a board was formed for the examination and licensing of persons qualified for the practice of medicine. The year 1832 was notable for the

establishment in Quebec of the first sanitary commission; a cholera ship arrived that year from Limerick and an extensive epidemic occurred both in Quebec and Montreal. So the story goes on, the dread of cholera being the main stimulus to sanitation; when the disease disappeared, action was diminished or discontinued, to be resumed when public alarm again called for special measures. The years 1832, 1849, 1854, and 1865 appear to have witnessed successive creations of boards for control of cholera. In 1867, when the various parts of Canada were combined into a single Dominion, the Canadian Medical Association was formed. As in the States, the comparative recency of official attention to vital statistics in Canada is striking. In the Province of Ontario it was only in 1869 that an Act "for the registration of births, marriages, and deaths" was passed, and it was not until 1882 that a Provincial Board of Health was established by the Ontario Government. About 7,000 deaths from small-pox occurred in the Province of Quebec in 1885, and naturally the epidemic stirred up appropriate preventive action.

Dr. Bryce is of opinion that on the whole the progress of public health in Canada has seemed slow, but the remarkable expansion of population since the beginning of the present century—the addition being 34 per cent. during the first ten years—has caused various new duties to be undertaken in relation to sanatoriums and other matters. So recently as 1919 a bill for establishing a Federal Department of Health was passed, providing that a physician shall be the deputy Minister of Health, and various existing services have been placed under the Department. Dr. Bryce concludes by referring to the effects of increasing urbanization of the population. He holds that "the complexity of modern life, and the great demands upon the emotional functions, have tended to produce a neurotic population. If, then, devotees of Hygeia are to find adequate responses to their prayers, their approach to her shrine must be through the temple sacred to Minerva."

BACTERIOLOGY.

Bacteriology inevitably occupies much space in the Jubilee volume. A long and valuable article is devoted to its history by Professor F. B. Gorham of Brown University, and it crops up in articles on State and municipal control of disease, water purification, milk, and medical entomology. The editor has wisely allowed each writer to tell his story in his own way, notwithstanding that it results in some overlapping and repetition.

Public Health Practice, Past and Present.

It is not proposed to follow Professor Gorham in his historical epitome from Athanasius Kircher to Leuwenhoek and Ehrenberg, or from spontaneous generation to the germ theory and Pasteur and Lister and all the workers inspired by them. Faith in bacteriology is, indeed, amply justified. Its value is unquestioned and unquestionable; but it may occur to a reader, especially to the reader of the contribution by Professor Gorham and that of Professor C. V. Chapin on State and municipal control of disease, that there is risk of the enthusiasm of the laboratories and of appreciation of modern achievements in disease prevention leading to some narrowness of view as to the scope and value of the methods followed before the world had the benefit of present knowledge. In referring to the creation of boards of health in certain States in 1869-70 Professor Gorham says that "sewage, sewers, and ventilation were the weapons depended upon to destroy the sources of contagion, then supposed to be filth, foul odours, and the decomposition and fermentation of animal and vegetable matter." Dr. Chapin tells, too, how Benjamin Rush believed that yellow fever and, indeed, most fevers were due to emanations from decomposing organic matter, and even imagined that a heap of decaying vegetables might cause an outbreak of malignant fever. The importance of contagion was forgotten, and the attention of sanitarians was almost entirely devoted to improving environment, these views being fostered by the theory and policy of English reformers.

There is no doubt that in the times of the English Board of Health—of Chadwick and Southwood Smith—and even later when Murchison wrote on continued fevers, the *de novo* origin of typhoid was accepted by some distinguished men, Murchison's conclusion being that though the disease once originated was communicable, it might be traced to "the emanations from decaying organic matter, or organic impurities in drinking water." This, however, was denied by Christison and John Hughes Bennett. Yet such beliefs,

though mistaken, tended to encourage cleanliness, and sanitary authorities were wisely inspired in making this their first line of defence, especially at a time when the public conscience had not awakened to the communal duty of providing hospitals sufficient for the segregation of ordinary infectious diseases—a provision which, in respect of scarlet fever and diphtheria, has after all not been as successful as was anticipated before the part played by "carriers" came to be realized. In course of time other discoveries will be made, and some parts of present procedure will no doubt be discarded for better measures. But if a new infectious disease were to become epidemic to-day, then, whilst bacteriologists were striving to unravel its mysteries in the laboratory, action by the health authorities would be for cleanliness and isolation. Speaking of the position half a century ago, Professor Gorham says: "This was the era of the filth theory of disease production, which continued for some thirty or forty years, and which is to-day just giving up its hold upon the health authorities of our cities and states." In the reviewer's opinion it will be unfortunate if, notwithstanding all the splendid discoveries of bacteriology, the filth theory is given up by health authorities. Outside the laboratories it is still the broad basis of health administration. Cleanliness of air, soil, and food constitutes the tripod on which sanitation should rest, and if that stool were kicked over there would be nothing so good to take its place. Dr. Chapin says that the physician and the nurse "have taken the place of the sanitary inspector and the police," but there is and will be abundant room for both classes of work, and the officers were not wasting time when they removed "dead cats and ashpiles." He is right regarding milk that "cleanly handling and prompt cooling mean few bacteria," also that cleanliness in the handling of food "is undoubtedly of real sanitary significance." For each infectious disease as it becomes understood special preventive measures are devised, and here bacteriology is invaluable; but behind and supporting it there remains cleanliness—personal, domestic, municipal, and national—making for the maintenance of general health, and good in its measure against every disease to which flesh is heir.

Science performed a great service in discovering that the infection of typhus, though the specific organism be unknown, is carried by lice. But bodily and domestic filth—dirt and foul air and darkness—are the conditions in which lice flourish, and if the insects are experimentally placed so that they can travel, on the one hand, towards clean air and light, and, on the other hand, towards foul air and darkness, the latter is the road they choose. Against typhoid fever cleanliness of milk and water remains a first line of defence, though the bacillus of the disease be recognizable by every medical student. Before the relation of rats to plague became known a great port in this country was invaded by that disease. Forthwith, in addition to hospital isolation of discovered cases, an anti-filth campaign was instituted and rigidly carried into effect. Besides house inspection, scavenging of streets and courts and premises of every kind, and removal of filth, whether vegetable or animal, wherever found, were included in the crusade. The disease did not spread, and we know now that these measures of filth removal and house purification, by operating against rodents and fleas, were of value against the spread of plague. Similarly house flies and other insects, which play so large a part in infection, are kept down by removal of the filth in which they breed, and, as agreed by Dr. Chapin, contamination of milk and other food is correspondingly lessened. Even the excessive attention paid to drain joints and traps, on the supposition that sewer gas conveyed infection, was not wholly lost. It is better that people indoors should breathe pure air than air polluted by drain emanations.

Not for a moment, however, is it suggested that the bacteriologists of the Jubilee volume give no credit to the work of the older generations of sanitarians. Indeed, they pointedly acknowledge it. As quoted with approval by Professor Gorham, Dr. Chapin says of the early promoters of public health that "their projects for civic betterment saved many lives and did much for human comfort and convenience," and Professor Gorham adds that "their mistakes were perfectly natural." But while it is right for the shoemaker to hold that there is nothing like leather, and for every worker to attach importance to his own speciality, a due sense of proportion is apt to be lost, and the administrative or executive sanitarian may express the hope that advances in bacteriology may never by their brilliant light so dazzle the eyes of public health authorities as to blind them to the importance of dirt in relation to disease.

In writing on immunity Professor Gorham notes the long gap between Jenner's discovery of vaccination in the latter part of the eighteenth century and Pasteur's work in the nineteenth. A discussion of Metchnikoff's theory of phagocytic immunity is followed by an account of the work on diphtheria and antitoxin by Loeffler, Roux, Yersin, Behring, and Kitasato. At the same time Nuttall, Büchner, Pfeiffer, and others entered on the study of blood serum in relation to immunity. Venereal diseases were being studied early in the present century. The agglutination studies by Widal and others were even earlier, and their application to the diagnosis of typhoid fever belongs to 1896. Serum sickness and anaphylaxis, opsonins and the opsonic index, are also briefly mentioned. In an eloquent passage, with which this notice of his essay on bacteriology may close, Professor Gorham says:

"Contagion is no longer feared as some intangible, unknown effluvia permeating the atmosphere against which we have no protection. Bacteriology has taught us that the communicable diseases are caused by specific micro-organisms which live and grow in the bodies of men and animals and plants; that when these disease-producing micro-organisms escape from their natural habitat they die more or less quickly; that the secretions and excretions coming rather directly from the bodies of the sick, and sometimes the well, are the real carriers of contagion. Bacteriology has taught us the parts played by the air, water, sewage, milk, and insects in the spread of disease, and has developed for us special methods of protection. Not only this, but bacteriology has taught us accurate methods of diagnosing disease, methods of specific immunization against disease, and, last but not least, methods of curing disease and saving lives by the use of vaccines, sera, and antitoxins. Could we but number the cases of disease prevented, the lives saved, by the adoption of these ideas in public health work we would know something of the debt which we owe to these indefatigable workers following in the footsteps of the illustrious Pasteur."

(To be continued.)

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on April 11th, 28 cases were considered and £323 voted to 23 applicants. The following is a summary of some of the cases relieved:

Daughter, aged 47, of M.R.C.S. Eng. who died in February. Applicant is left quite unprovided for, as her late father was in receipt of a pension which died with him. She requires temporary assistance while looking round for something to do to earn a living; she hopes to retain the furniture in the hope of procuring a small house in order to let apartments. Voted £15.

Widow, aged 43, of M.D. Aberd. who died in March. Widow and four children at present unable to obtain any income owing to legal delays in realizing estate. The eldest son is dying of tuberculosis. Some three years ago the Fund gave £5 to the father owing to ill health. Voted £10.

Daughter, aged 70, of M.B.C.S. Eng. who died in 1882. Applicant has an annuity of £31 and receives help from friends, but has several bills to meet amounting to £32. She has previously received help from the Fund amounting to £48. Rent and rates amount to £18 per annum. Voted £25 towards paying off debts.

Surgeon, aged 77, who cannot secure an appointment, and has had to sell his belongings so that he and his wife could subsist. Only income, old-age pension, 10s. per week. The son is an invalid and unable to help. Rent amounts to 11s. per week. Voted £25.

Widow, aged 65, of M.R.C.S. Eng. who died in 1928. Applicant was left unprovided for, and earns a living as an office cleaner at £12s. 6d. a week, and works from 8 a.m. to 6 p.m.; her rent and insurance cost 5s. 4d. a week. Applicant is now suffering from "housemaid's knee" (spondylitis). Voted £12 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, K.B.E., C.B., F.R.C.S.; at 11, Chandos Street, Cavendish Square, London, W.1. The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessities, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

THE thirty-first Congress of the French Association of Surgery will be held in Paris at the Faculty of Medicine on Monday, October 2nd, under the presidency of Professor Henri Hartmann, when the following subjects will be discussed: (1) Results of bone grafting, introduced by Cuvier of Paris, and Rouvillois of the army medical staff. (2) Remote results of operation on the large vessels, introduced by Leriche of Lyons and Paul Moore of Paris. (3) Technique and results of extirpation of tumours of the large intestine (excluding rectum), introduced by Abadie of Oran and Ockinczyk of Paris. Further information can be obtained from the General Secretary, Dr. J. L. Faure, 10, Rue de Seine, Paris.

British Medical Association.

CURRENT NOTES.

Annual Meeting, Glasgow, 1922.

THE ninetieth Annual Meeting of the British Medical Association will be held at Glasgow this summer, under the presidency of Sir William Macowen, LL.D., F.R.S., Regius Professor of Surgery in the University, who will deliver his address to the Association on the evening of Tuesday, July 25th. The sectional meetings for scientific and clinical work will be held as usual on the three following days, the mornings being given up to papers and discussions and the afternoons to clinical and laboratory demonstrations. The Annual Representative Meeting will begin on the previous Friday, July 21st. The provisional programme for the scientific work of the meeting and the names of the officers of the various sections were printed in the SUPPLEMENT of May 13th (p. 173); brief notes of the sectional arrangements, as these are made, appear from time to time in the JOURNAL. Announcements regarding the accommodation for visitors at Glasgow have appeared in the SUPPLEMENT of April 15th (p. 105) and April 29th (p. 123). The last day of the meeting, Saturday, July 29th, in accordance with the custom of previous Annual Meetings, has been set apart for excursions to places of interest in Glasgow and the neighbouring West Highlands. An illustrated article, published in the JOURNAL of April 22nd, p. 649 (the fourth of the series), gave a preliminary sketch of the neighbourhood of Glasgow. Further descriptive notes will be published in subsequent issues.

The Position at Ebbw Vale.

The position at Ebbw Vale continues to justify the prophecies that have been made about it. Of the nine doctors imported by the Workmen's Committee two have already left and another is expected to leave shortly. The Workmen's Committee, led by Mr. Evan Davies, M.P., is making the most strenuous efforts to persuade the workmen to stick to the Committee, irrespective of the nature of the service provided by it, and not to exercise their choice in favour of their old doctors. The doctors who have been dismissed have, through the Cardiff, Monmouthshire, and Bristol Divisions, issued an appeal to the local consultants for their support in this struggle to prevent the standard of remuneration being lowered out of all proportion to the cost of living or of carrying on practice.

The Post of M.O.H. for Stafford.

THE "Important Notice" in connexion with the appointment of Medical Officer of Health for the Municipal Borough of Stafford was through inadvertence not withdrawn from last week's issue of the JOURNAL. The Notice was originally inserted because the salary offered for the post did not conform to the minimum recognized by the Association, but as

the Municipal Borough Authority has agreed to a salary of £700 per annum the post was advertised in last week's JOURNAL and the Important Notice has been withdrawn from this week's issue. A careful scrutiny is made of all the advertisements before they are inserted in the JOURNAL, and members can take it for granted that if an advertisement appears in the JOURNAL there can be no objection so far as the Association is concerned to an application being made in connexion therewith.

Meetings of Branches and Divisions.

LANCASHIRE AND CHESHIRE BRANCH: ROCHDALE DIVISION. A MEETING of the Rochdale Division was held in the Town Hall, Rochdale, on May 10th, with Dr. BATEMAN in the chair. An address was given by Dr. T. EASTHAM, K.C., on "Medico-legal difficulties."

Hints on Medico-Legal Cases.

Dr. Eastham began by saying that doctors were, as a rule, poor witnesses. This he attributed to the fact that they attended at their surgeries in the morning and visited patients up to the moment of going into court, and were thus generally unprepared. It was of the greatest importance that medical men should not go into court without preparation; they should know their facts, consult the latest books, and regard the case seriously. At the time of the first examination it was advisable to make good notes, taking great care to preserve the original notes for future reference if necessity arose. The notes must be dated, and contain the name of the person, age, and residence, and also the date and place of examination. The patient must be asked what happened, and his reply written down; he should also be asked if there was anything else he complained of until he had told everything and replied that there was nothing else to report. The notes should be read over to the patient, who should be asked who was his medical attendant. Notes should also be taken of the result of careful examination. The original notes should be retained and only a copy supplied. A record of subsequent attendance and treatment should be kept. In hernia cases it was necessary to note whether the hernia was direct or indirect. The medical practitioner should read over his notes before going into court. It was undesirable to state in the report what sum the insurance company should settle for; all that was necessary was to give the result of the examination and to state if another examination was desired. In calculating any sum payable exaggeration must be avoided.

Dr. Eastham said that there was no such thing as professional privilege in law courts where medical men were concerned; it applied only to lawyers. If asked to divulge something, the medical practitioner should ask the judge if he was compelled to answer the question, and should answer according to the judge's advice; he would then have done his duty. With reference to the question of a doctor disclosing a crime, that was a legal matter. It was the duty of every citizen—doctors included—to inform the police when they discovered that a crime had been committed. In regard to civil liability a doctor must have a reasonable amount of

knowledge and skill, and if he failed in treating a case he was liable to have an action brought against him. If such a thing happened the doctor should consult a good solicitor, and several of his medical brethren to ascertain their views as to his liability, and act accordingly. It was of no use a doctor defending a case if liable; it was best to get it settled at once. A medical practitioner who used a motor car should take care that he was insured in a reliable company for third-party risks; he should carefully examine the proposal form and see that his answers were correct.

Several questions were subsequently asked and answered; and on the motion of Dr. BATEMAN, seconded by Dr. GEDDES, a hearty vote of thanks was unanimously accorded to Dr. Eastham for his address.

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.

Discussion on Infant Mortality.

At a meeting of the Lewisham Division of the British Medical Association, held on April 25th, Dr. T. E. WHITE opened a discussion on the problem of infant mortality.

After some remarks on the subject of limitation of families, and complimentary references to Dr. Gibbons's lecture on sterility, published in the JOURNAL of March 18th (p. 427), Dr. White referred to the last report of the Registrar-General on births and deaths, showing that the births were 18.5 per 1,000 of the population, and comparing this with those of 1914 and 1890. The death rate in the last report showed a mortality of 13.7 per 1,000, thus the natural increase was less than 5 per 1,000. Bad as this appeared on the surface, the actual conditions were much worse. Emigration was increasing, due to scarcity of employment at home and the inducements held out by our colonies to attract emigrants from this country. The colonies were exacting in their demands, and would only accept those whose antecedents, family history, and physical fitness met with approval. The result was that this country was being depleted gradually of its A1 population, and accordingly the C3 class would increase arithmetically and geometrically. This was the grave prospect that had to be faced—a lowered birth rate, lessened increase of population, and a high emigration rate. Under ordinary conditions emigration and immigration ought to balance each other, but in our country immigrants were for the most part unprofitable and undesirable aliens. In America and the colonies immigrants were a source of strength; in England they were a source of weakness.

The infant mortality under one year in 1919 was 89 per 1,000 births registered; this was the lowest on record. If the powers working for good continued a rate of 50 per 1,000 might reasonably be expected in a few years. Dr. White next turned to the subject of illegitimate births and deaths. The number of illegitimate children born in 1919 was 41,876, or 6.05 per cent. of all births, while the mortality under one year amounted to 172 per 1,000 births. Thus the illegitimate death rate was nearly double that of legitimate infants; in other words nearly 10,000 avoidable deaths occurred. The country could not afford to lose this number without making an effort to equalize the balance between those born in and out of wedlock. With a diminishing birth rate every human life had an enhanced value. How could 10,000 lives be added yearly to the population? The remedy he proposed was an extension of the Foundling Hospital system; but the term "State children" should be substituted for "illegitimate children." The State should take possession of, and be responsible for, the care and upbringing of all its wards. Foundling hospitals on the lines of that in London should be established in every county or group of counties. The father should not be relieved of the responsibility of supporting his offspring, every effort should be made to exact it to the last farthing; but it was well known that when a paternity order had been made the difficulty of enforcing it was very great, so that under the most favourable conditions only a small proportion of the children would be self-supporting. The balance should be paid by the State.

Association Notices.

NOTICES OF MOTION BY DIVISIONS FOR THE ANNUAL REPRESENTATIVE MEETING, GLASGOW, 1922.

Report on Hospital Policy of Association.

Correction.—The Notice by Brighton affecting para. 33 of the Report on Hospital Policy (published in SUPPLEMENT of April 29th, 1922, p. 118) should be amended to read as follows:

By BRIGHTON:

That the following be added to para. 33:

In each case where the Board of Management advises the Medical Staff that the sum or sums received from a patient have been obtained only from that patient and without any other financial assistance, and are insufficient to pay more than the whole of the cost of maintenance of that patient, and that the financial position of the patient is such as to render him unable to make any further payment, the Medical Staff of the hospital should decline to receive any part of such payments for the Staff Fund.

By OLDHAM:

That para. 46 of the Report on the Hospital Policy of the Association be deleted.

Provision of Surgical Dressings to Insured Persons.

By CHESTERFIELD:

That the retail provision of surgical dressings to insured persons by retail chemists is unduly extravagant, and in many cases not in accordance with the principles of asepis, and that the Council be instructed to take steps to obtain a revision of the Regulations under the National Health Insurance Acts in this respect.

Correction.—In Item 7 (Amendment by Edinburgh and Leith) of the Provisional Agenda published in last week's SUPPLEMENT (p. 169, col. 1) the word "amendment" in the first line of the paragraph between the two drafts should be altered to "alternative."

SUGGESTED CHANGE OF NAME OF DIVISION.

NOTICE is hereby given to all concerned of a proposal made by the Executive of the Westminster Division that the Division be known as the "Westminster and Holborn Division."

The matter will be determined in due course by the Council. Any member affected by the proposed change and objecting thereto is requested to write, giving reasons therefor, to the Medical Secretary, 429, Strand, W.C.2, not later than June 20th, 1922.

TABLE OF DATES.

May 27, Sat.	Last day for receipt at Head Office of voting papers for election of 24 Members of Council by grouped Home Branches (where contests).
June 3, Sat.	Publication in SUPPLEMENT of results of Council elections by grouped Home Branches.
June 10, Sat.	Nomination papers available, at Head Office, for election of 12 Members of Council by grouped Home Representatives.
June 14, Wed.	Council Meeting, 429, Strand, at 10 a.m.
June 23, Fri.	Last day for election of Representatives and Deputy Representatives.
June 24, Sat.	Supplementary Report of Council appears in SUPPLEMENT.
June 30, Fri.	Last day for receipt at Head Office of notification of election of Representatives and Deputy Representatives.
July 7, Fri.	Last day for receipt at Head Office of Amendments and Riders for Annual Representative Meeting Agenda.
July 21, Fri.	Annual Representative Meeting, Glasgow, 10 a.m. Nominations for election of 12 Members of Council by grouped Representatives to be received (at A.R.M., Glasgow) by this date.

ALFRED COX, Medical Secretary.

BRANCH AND DIVISION MEETINGS TO BE HELD.

DUNDEE BRANCH.—A clinical meeting of the Dundee Branch will be held at the Royal Infirmary, Dundee, on Friday, June 2nd, to be followed by a dinner. Members having cases or exhibits to show are asked to communicate with either of the Secretaries (Dr. R. C. Buist, 166, Nethergate, Dundee, and Dr. G. Rankine, 201, Albert Street, Dundee) not later than Saturday, May 20th.

KENT BRANCH: MAIDSTONE DIVISION.—A clinical demonstration will be given at the West Kent Hospital on Thursday, May 25th, by Mr. Alan Todd, M.S., F.R.C.S., Orthopaedic Surgeon to the West Kent Hospital. A large series of orthopaedic cases will be shown, and methods of diagnosis and treatment demonstrated.

LANCASHIRE AND CHESHIRE BRANCH: MID-CHESHIRE DIVISION.—A meeting of the Mid-Cheshire Division will be held at the Unicorn Hotel, Altrincham, on Thursday, June 15th, at 3.15 p.m., when Dr. John Hay (Liverpool) will give a British Medical Association lecture on "Some Aspects of Cardiac Disease." Tea will be provided at 4.30 p.m.

METROPOLITAN COUNTIES BRANCH.—The annual general meeting of the Metropolitan Counties Branch will be held at 429, Strand, W.C., on Friday, June 23rd, at 4 p.m. Business: (1) Report of scrutineers as to the election of new officers; (2) Annual Report of Council; (3) President's address by Mr. N. Bishop Harman, entitled "London: the triumph of medicine."

METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.—The annual meeting of the Lewisham Division will be held on Tuesday, May 23rd, at 8.45 p.m., at Rosedale, 42, Sydenham Road, S.E.26. Dr. G. W. Charsley will occupy the chair. Agenda: Election of officers; Discussion on (1) Annual Report of Council, 1921-22 (SUPPLEMENT, May 6th, 1922); (2) Provisional Agenda of Annual Representative Meeting, Glasgow, 1922 (SUPPLEMENT, May 13th, 1922). Any other business.

NORTH OF ENGLAND BRANCH: DARLINGTON DIVISION.—A meeting of the Darlington Division will be held at Greenbank Hospital on Thursday, May 25th, at 8.30 p.m. Dr. T. Eustace Hill will address the meeting on "The Public Health Service and its relation to the General Practitioner."

SOUTH MIDLAND BRANCH: BEDFORD DIVISION.—A general meeting of the Bedford Division will be held at the Bedford County Hospital to-day, Friday, May 19th, at 3 p.m., to consider the Annual Report of Council (BRITISH MEDICAL JOURNAL SUPPLEMENT, May 6th, which members are asked to bring to the meeting). Tea will be provided.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: NORTH GLAMORGAN AND BRECKNOCK DIVISION.—A meeting of this Division will be held at Pontypridd on Thursday, June 29th, when a British Medical Association lecture will be delivered by Dr. H. Morley Fletcher on "Treatment in Recal Disease."

SOUTHERN BRANCH: WINCHESTER DIVISION.—The annual meeting of the Winchester Division will be held on Thursday, June 8th, at 3.30 p.m. at the George Hotel, Winchester. Dr. G. C. Anderson, the Deputy Medical Secretary, will give an address entitled "What are the advantages of belonging to the British Medical Association?" All non-members of the Association residing in the neighbourhood are invited to be present.

WARRINGTON DIVISION: HARROGATE DIVISION.—A special meeting of will take place on Thursday, May 25th, at the Harrogate Hotel. Agenda: (a) Annual Report of Council (BRITISH MEDICAL JOURNAL SUPPLEMENT, May 6th, 1922); (b) Hospital Policy of the Association (SUPPLEMENT, February 25th, 1922); (c) Election of members are asked to bring the above-named agenda. The following members will speak: Greenwood (Ripon), Steven, and Mr. Frankling.

STAFFORD DIVISION.—The annual meeting will be held at the Church House, on Friday, May 26th, at 8.30 p.m. Agenda: Annual Report of Executive Committee; Election of Chairman, Vice-Chairman, Honorary Secretary, Four Representatives on Yorkshire Branch Council, Two Representatives in Representative Body, Two Auditors, Executive Committee.

DENTAL BOARD OF THE UNITED KINGDOM.

The second session of the Dental Board of the United Kingdom was opened on May 9th, the Right Hon. F. DRYE ACLAND, M.P., Chairman of the Board, presiding. The principal business was the consideration of twenty disciplinary cases, which occupied three days. In each case the offence charged against the registered dentist was that of "covering" an unregistered person.

Chairman's Address.

In his preliminary address the Chairman said that the number of applications for registration which had been received was 6,765, and in 4,085 of these the Board was already satisfied, and the names had been published. Of this number 2,200 were persons who claimed to have been in practice for five of the last seven years, 1,400 were members of the Incorporated Dental Society, 275 were mechanics, 116 were persons in practice at the time of the passing of the Act who had, like the mechanics, to undergo an examination before being registered, and 94 were chemists who claimed that at the commencement of the Act they had a substantial practice as dentists. One of the most difficult matters which had occupied the attention of the Board and its Registration Committee was the claims of ex-service men. As the Act laid down a general requirement of five years' actual practice in dentistry, it was difficult to say that in the case of ex-service men the Board should be satisfied with a shorter period, and it had been thought right to require, if the period of practice was less than five years, that an examination should be taken (without fees, in the case of ex-service men). The Board was willing to count the time spent in the army in carrying out the dental treatment of troops in considering the period for which a person had been engaged in dentistry as his principal means of livelihood; but the War Office had made it clear that the only persons so employed were persons registered under the Dentists Act of 1878, who were granted temporary commissions, and the Registration Committee had considered itself debarred from entertaining the claims of persons who appeared only to have carried a forceps in their haversack for use in the case of an aching tooth. The arrangements were proceeding steadily and satisfactorily with regard to the holding of the first prescribed examinations in July. The examination would be held if necessary at four centres—in London, Manchester, Edinburgh, and Dublin.

Much misapprehension existed with regard to the matter of covering. Some thought that if they had no branch practice conducted by an unregistered person, and only employed such a person on their own premises, no offence was committed. This view was incorrect. It was permissible for an unqualified person to adjust in the mouth a denture which he had made in the workroom, or to do mechanical work of a similar kind, but it was not permissible for him to extract teeth or attend or treat patients in any matter requiring professional knowledge and skill. Others thought that if they employed a bona fide student they would be protected by the words in the Warning Notice issued by the General Medical Council—that the restriction was not to prevent the instruction of

students. Students, however, might only be registered as pupils of registered practitioners for mechanical work, and to employ a third-year or fourth-year student to attend or treat patients would not come under the instruction of students and would not be permissible. He feared that in a considerable proportion of the cases which were to come before the Board an offence had been knowingly committed which was a serious fraud upon the public and a gross piece of unfairness to brother practitioners who had strictly conformed to the Regulation of the General Medical Council.

Position of Ex-Service Men.

A letter was read from the War Office stating that during the war the only persons employed for the purpose of carrying out dental treatment among British troops were those registered under the Dentists Act then in force. These were granted temporary commissions either in the R.A.M.C. or in the General List of the army. Persons employed as dental mechanics were enlisted as soldiers in the R.A.M.C. or attached thereto from other arms. A communication was also read from the Ministry of Labour in regard to the position of disabled ex-service men trained as dental mechanics. This contained a resolution passed by the National Trade Advisory Committee (Dental Mechanics) stating that the training given to such men had been solely directed to making them efficient as dental mechanics, and was never intended and was quite inadequate to fit any person so trained for the practice of dentistry as such. The resolution was passed in view of the fact that dental mechanics trained under the auspices of the Ministry of Labour are in some cases putting forward their training as ground for consideration for admission to the Dentists Register.

Disciplinary Cases.

The first of the twenty disciplinary cases brought before the Board was that of an Irish dentist, registered as "in practice in 1878," who was charged with having permitted an unregistered person to practise in his name or in partnership with or as assistant to him. The unregistered person in this case was the dentist's son, who had been employed in one position and another in his father's business, at first in the workshop, for a number of years. The defendant expressed regret that he had inadvertently transgressed the regulations. There were some compassionate circumstances in the case, the defendant having lost the whole of his property and business in the rebellion of 1916.

After a long consideration *in camera* the Chairman announced the procedure in these disciplinary cases. The Board, after hearing each case, would merely record its finding on the facts, and after all the cases had been brought before it the judgement in the cases found proved would be considered. In this case the Board found the facts alleged against the dentist in question to have been proved to its satisfaction.

At the conclusion of the hearing of the whole of the cases those defendants against whom the Board had found the facts to have been proved to its satisfaction were recalled, and the Chairman communicated to them the measure which the Board had decided to take. Their names were:

Randall Patrick MacDonnell (Dublin), Hugh de Bosco Askew (Werkington), Arthur Wellesley Overell (Plymouth), Robert Sleigh (Southport), Samuel John Zachary (Leeds), Herbert William George Poole (Sheffield), Peyton Charles Herbert Fox (Gloucester), Alec George Knight (Southsea), James Tennick George Marshall (Aldershot), John Bridge Road, London, Alfred William (London), Thomas Henry Gee Moore (Stoke Newington, London).

The Chairman said that in 1897 the General Medical Council issued a warning in regard to covering which had been circulated to all members of the profession on several occasions. Registered practitioners were warned that any one of them who knowingly enabled an unqualified and unregistered person to attend, treat, or perform any operation upon a patient was liable on proof of the fact to have his name erased from the Register. This warning did not apply so as to restrict the legitimate employment of skilled mechanics under due supervision. The Board took a grave view of the practices which had been proved against the practitioners concerned, though the gravity of the practitioners' conduct varied very much in the different cases.

Taking all the circumstances into account, and particularly considering the fact that some of the persons concerned had incriminated themselves by signing statements with regard to their assistants, the Board was prepared to give the defendants an opportunity to prove that they were capable of more worthy conduct in the future, for which purpose it had decided not at once to proceed to its findings on the facts proved, but to postpone all the cases to the November session, 1922, when the respondents would be required to attend and to produce satisfactory evidence as to their conduct in the interval. If they could not do so he need not say that the consequences would be most serious, and that the Board would proceed at once to make a very strong recommendation to the General Medical Council. He added that in future in any case in which this complaint was made and the facts were proved—namely, that the practitioners had permitted unregistered persons to practise in their name or in partnership with or as assistants to them, thereby enabling the unregistered persons to practise as if they were registered—it must not be assumed that a similarly lenient course would be followed.

The remainder of the sitting of the Board was held *in camera* to consider various reports of committees.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following notifications are announced by the Admiralty:—Surgeon Commanders: J. D. Keir to the *Lucia* on recommissioning, C. A. G. Phipps to the *Maidstone* on recommissioning, G. T. Verry to the *Ganges II* for R.N. Sick Quarters, Shotley, J. H. McDowall to the *Caradoc*, C. H. Dawto to the *Impregnable*, additional appointments to the *Victory XI* for R.N. Hospital, Portland, Commanders: M. B. Macleod to the *Iron Duke*, dated in the *Maine*, F. St. B. Wickham, O.B.E., to the *Alecto*. Surgeon Lieutenants: A. de B. Joyce to the *Veronica*, D. F. McGregor to the *Beulbow*, J. C. Sinclair to the *Adamant*. Surgeon Commander L. Kilroy has been placed on the retired list with the rank of Surgeon Captain.

ROYAL ARMY MEDICAL CORPS.

Major General Sir Maurice P. C. Holt, K.C.B., K.C.M.G., D.S.O., K.H.S., retired on retired pay, April 15th, 1922 (substituted for notification in the *London Gazette*, April 18th, 1922).

Colonel B. Martin, C.M.G., late R.A.M.C., to be Commandant, Royal Army Medical College.

Colonel L. P. More, late R.A.M.C., from half pay is restored to full pay, October 10th, 1920, with precedence next below J. McD. McCarthy. (Substituted for notification in the *London Gazette* of October 27th, 1920, and May 9th, 1921.)

Lieut.-Colonel A. R. C. Parsons retires on retired pay. Major and Brevet Lieut.-Colonel G. F. Sheehan, D.S.O., half-pay list, late R.A.M.C., retires on retired pay on account of ill health contracted on active service.

Major A. E. G. Fraser is placed on the half-pay list on account of ill health.

The following to be acting Lieutenant-Colonels: Majors H. Harding (November 17th, 1920, to November 3rd, 1921), E. G. Anthony (April 16th, 1921, to February 15th, 1922), C. G. Thomson, D.S.O. (May 21st, 1921, to 12th, 1922), Brevet Lieut.-Colonel R. A. Bryden, D.S.O. (July 19th, 1921, to 31st, 1921), Captain J. H. Fletcher, D.S.O., M.C. (December 8th, 1920, to 31st, 1921).

Captain and Brevet Major N. V. Lothian, M.C., relinquishes the acting rank of Major.

Captain D. T. M. Large relinquishes the temporary rank of Major.

The following Captains to be temporary Majors: Brevet Major G. A. Blake (May 10th, 1920, to January 24th, 1921), W. K. Campbell, D.S.O., M.C. (November 7th, 1920, to March 31st, 1921), W. Frier (January 19th, 1921, to January 22nd, 1922), W. M. Cameron (May 15th to October 16th, 1921).

The following Captains to be acting Majors: F. R. S. Slaw, M.C. (November 7th, 1920, to November 3rd, 1921), G. A. E. Argo, M.C. (January 28th, 1921, to 31st, 1921), B. C. O. Sheridan, M.C. (May 10th, 1921), W. K. Campbell, D.S.O., M.C. (July 19th, 1921).

The following officers relinquish their commissions:—Temporary Majors and retain the rank of Major: A. G. Higgins, A. E. Atkinson, C. E. F. Mount-Higgs. Temporary Captains and retain the rank of Captain: E. P. Penko, J. K. Hamilton, H. J. Theriault, P. J. Power, temporary Captain G. B. Egerton, temporary Lieutenant J. D. Leahy, M.C., and retains the rank of Lieutenant.

DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.—Section of Odontology: Mon., 8 p.m., Annual General Meeting. Papers: Mr. E. Sprawson: The Extra Cusp commonly found on the Antero-internal Aspect of the Maxillary First Permanent Molar in Man. Mr. H. C. Malleson: Notes on Dental Histology. Section of Medicine: Tues., 5.30 p.m., Annual General Meeting. Papers: M. P. L. Vielle: A Method of Estimating Diuresis. Dr. William Hunter: Nervous Disorders of Severe Anaemias in relation to their Infective Lesions and Blood Changes. Section of Urology: Thurs., 8.30 p.m., Annual General Meeting. Papers: Professor Frederick Hobday: Urinary Calculi in Animals (with specimens and skiagraphs). Mr. Kenneth Walker: Accessory Sexual Glands of Rhinoceros, Flying Wombat, Ornithorynchus, Zebra, and Tapir. Section of Study of Diseases in Children: Fri., 4.30 p.m., Cases, 5 p.m., Annual General Meeting. Section of Epidemiology and State Medicine: Fri., 8 p.m., Election of Officers and Council. Paper: Dr. R. Dudfield: Reforms Needed in the Notification of Tuberculosis. Section of Bacteriology and Climatology: Sat., Annual General Meeting at Cambridge. A train leaves Liverpool Street at 10.5 a.m. Exhibits and demonstrations by Dr. W. H. L. Duckworth and Dr. T. S. P. Strangeways. Particulars may be had from Dr. C. F. Sonntag, 80a, Belsize Park Gardens, N.W.3.

UNIVERSITY OF LONDON, Rooms of Royal Society of Medicine, 1, Wimpole Street, W.—Lectures, 5 p.m.:—Mon., Professor F. Vidal: Anti-anaphylaxis. Thurs., Professor H. Vaquez: Do l'Erythémie (Maladie de Vaquez-Osler).

POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.—Wed., 5 p.m., Sir St. Clair Thomson: Surgical Anatomy of the Nose and Accessory Sinuses (lantern demonstration). At Western General Dispensary, Marylebone Road, N.W.1.—Mon. and Thurs., 4.45 p.m., Dr. B. Myers: Gastro-intestinal Affections in Children.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION, Western Infirmary.—Wed., 4.15 p.m., Dr. James Carslaw: Medical Cases.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Mr. Fairbank: Flat-foot.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, Paddington, W.2.—Thurs., 5 p.m., Professor E. H. Starling: Some New Experiments on the Kidney.

LONDON HOSPITAL MEDICAL COLLEGE, E.—Dr. Millais Culpin: Psychoneuroses. Tues., 5.15 p.m., Dreams. Fri., 5.15 p.m., Symptomatology. Surgical Unit, Fri., 4.15 p.m., Sir Hugh Rigby: Carcinoma of the Rectum.

LONDON LOCK HOSPITAL, 91, Dean Street, W.1.—Mon., 5 p.m., Mr. C. Gibbs: Ante- and Post-natal Treatment of Syphilis. Tues., 2.30 p.m., Mr. J. E. R. McDonagh: Clinical Demonstration (with paintings). Thurs., 2.30 p.m., Mr. W. V. Corbett: Interpretations of Wassermann Reaction. 4.30 p.m., Mr. S. Joly: Complications of Gonorrhoea in the Male. Fri., 4 p.m., Mr. J. Abraham: Syphilis in Women.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland Street, W.1.—Mon., 5.30 p.m., Dr. B. T. Parsons-Smith: Diagnosis of Aneurysm of the Thoracic Aorta.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.1.—Mon., Tues., Thurs., Fri., 2 p.m., Out-patient Clinics. Mon., 3.30 p.m., Dr. Walshe: Paraplegia. Tues., 3.30 p.m., Dr. Adie: Syringomyelia. Wed., 2.15 p.m., Dr. Taylor: Clinical Demonstration. Thurs., 3.30 p.m., Dr. K. Wilson: Disseminated Sclerosis. Fri., 3.30 p.m., Dr. Collier: Aphasia. Tues. and Fri., 9 a.m., Operations.

Mon. and Thurs., 12 noon, Dr. Greenfield: Neuro-Pathology. Tues. and Fri., 12 noon, Dr. Howell: Anatomy and Physiology. Wed., Dr. Adie: Demonstration on Methods of Examination.

NONN-BAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Daily, 10.30 to 5 p.m., Intensive Course. Lectures, 4.30 p.m.:—Mon., Professor R. T. Hewlett: Laboratory Findings and their Use in Diagnosis and Treatment. Tues., Dr. A. J. Whiting: Treatment of Heart Failure. Wed., Mr. J. B. Banister: Inflammation of the Female Pelvic Organs. Thurs., Dr. J. Motcalf: Radiological Examination of the Heart and Mediastinum.

ST. MARYLEBONE GENERAL DISPENSARY, Welbeck Street, W.1.—Infant and Child Welfare, Dr. Eric Pritchard: Mon., 6 p.m., Digestive System: Thurs., 6 p.m., Minor Ailments.

SOUTHEAST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Onseley Road, Putnam, S.W.—Wed., 4 p.m., Mr. J. P. S. Frazer: Some Erroneous Ideas of Structure and Function as they come into Everyday Work.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith, W.—Mon., 5 p.m., Mr. D. Armour: Cerebral Surgery. Tues., 5 p.m., Dr. Perot: Late Manifestations of Congenital Syphilis. Wed., 4 p.m., Sir R. Armstrong-Jones: Common Forms of Mental Disease (at Claybury). Thurs., 5 p.m., Dr. Beddard: Chronic Rheumatism. Fri., 5 p.m., Mr. Addison: Erysipela and Suppurative Pericarditis. Sat., 10 a.m., Mr. Simmonds: Orthopaedics.

British Medical Association.

OFFICES AND LIBRARY, 429, STRAND, LONDON, W.C.2.

Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded, if desired, on application to the Librarian, accompanied by 1s. for each volume for postage and packing.

Departments.

SUBSCRIPTIONS and ADVERTISEMENTS (Financial Secretary and Business Manager. Telegrams: Articulate, Westrand, London).

MEDICAL SECRETARY (Telegrams: Mediscera, Westrand, London). Editor, *British Medical Journal* (Telegrams: Attitology, Westrand, London).

Telephone number for all Departments: Gerrard 2530 (5 lines).

- 31 Wed. London: Finance Committee, 2.30 p.m.

APPOINTMENTS.

Cox, William J., M.B., Ch.B., D.P.H., Medical Officer of Health for the Urban District of Watford.

DAW, S. W., M.B., B.S., F.R.C.S., Honorary Surgeon in charge of the Orthopaedic Department at the Leeds General Infirmary.

HANFIELD-JONES, R. M., M.S. Lond., F.R.C.S., Assistant Director of the Surgical Unit, St. Mary's Hospital Medical School.

MIRCHELL, Leonard J. C., M.D., F.R.C.S., Melbourn Hospital, vice Sir James B.

THOMSON, J. H., M.B., Ch.B., Leeds General Infirmary.

WALKER, Miss Enid, L.D.S. Eng., Dental Surgeon to the South London Hospital for Women.

EDINBURGH ROYAL INFIRMARY.—Resident House-Surgeon: R. W. Payler Hall, L.R.C.P. and S.E., L.R.F.P. and S. Glasg., to Professor Alexis Thomson (five months). Clinical Assistant: Miss Mary F. Liston, M.B., Ch.B., to Mr. Lees (twelve months).

GLASGOW ROYAL INFIRMARY.—Extra-Dispensary Surgeon: George H. Stevenson, O.B.E., M.C., M.B., Ch.B., D.P.H.

Anaesthetist: R. Gloag Battersby, L.R.C.P.

Glasg. Extra-Dispensary Surgeon for A. Douglas Hillier, L.D.S.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

MARRIAGE.

RUSSELL-MACKAY.—On May 1st, at Ilmington Oratory, London, by the Rev. Father Crewse, George Andrew Russell, M.R.C.S., L.R.C.P., of Derby, to Cecily, widow of the late Dr. William Hugh Mackay.

DEATH.

BROWN.—On April 30th, at The Glen, Dore, near Sheffield, Horace George Brown, M.A., M.R.C.S., L.R.C.P., elder son of the late Dr. G. A. Brown, of Tredegar.

British Medical Journal.

SATURDAY, MAY 20TH, 1922.

THE SEARCH FOR SPECIFIC REMEDIES.

IN the lay mind there dwells an instinctive belief in specific "cures" for disease, and, as Dr. H. H. Dale observed in his Friday evening discourse at the Royal Institution last week, the idea of finding for each disease a remedy specially adapted to its direct cure cannot be claimed as a development of the scientific era of medicine. On the contrary, the more primitive and unscientific the state of medicine in the past the more readily did its practitioners and their patients believe in such a possibility. One of the first results of the progress of medicine towards a place among the exact sciences was an attitude of general scepticism—often, indeed, well deserved—towards all the claims made for those drugs which earlier generations had, in simple faith, accepted as specifics. Nevertheless, the old empiricism stumbled upon some remedies which were definitely specific for certain forms of infection, and many will agree that modern science, with all its resources, has found no better remedies than some of these, nor perhaps even any quite as good. In the present century, however, a pronounced change has come over the picture, and we cannot do better than follow the broad strokes of the brush with which Dr. Dale laid in its chief features.

The first thing to note is that during the past twenty years or so the services of the synthetic chemist have been called in by the physician, and a serious attempt has been made to produce new substances having a direct curative effect in certain definite forms of infectious disease. The new impulse did not come directly from the study of those few traditional drugs which had succeeded in keeping their reputation as specific remedies; it came from an intensive study of the phenomena of immunity to infection. It was realized more fully and more clearly than ever before that Nature produced her own remedies for certain infections. Experiment and study showed that in the blood of the infected man or animal substances appeared which were adapted specifically to combine with and neutralize the poisons formed by the infecting organism, or to combine with constituents of the living protoplasm of the infecting organism, and so produce its disintegration, or impair its vitality, or render it susceptible to digestion by the wandering cells of the blood; it was in one of these ways that the progress of the disease was arrested, recovery from the immediate attack brought about, and resistance to further similar infection established. These "antibodies" (as they were uncouthly called) were found to be highly specific in two senses: they were indifferent to other kinds of infecting organisms or bacterial toxins, and, more important, they were harmless to the body itself. They were ideal therapeutic substances in the sense that they were intensely inimical to the infection and at the same time harmless for the infected person. The question then arose whether it would be possible to employ the growing resources of organic synthesis to construct artificial substances of known chemical composition which, like the natural antibody, would combine with the protoplasm of the infecting parasite in preference to the body cells of the host. Such remedies, it was hoped, would make effective intervention possible in those many forms of infection against which no curative antibody seems to be formed naturally. The quest might have seemed wellnigh hopeless, for almost nothing was known of the

parasites concerned in these diseases; often they were only to be distinguished by their property of uniting with their particular antibody, about the chemistry of which we are still largely in the dark. Thus the problem was to prepare by chemical synthesis a compound which should have a specific affinity for one unknown substance rather than for another unknown substance, the only thing clear about both substances being their close similarity. This was an enterprise needing a courageous spirit as well as a fertile imagination, and we must recognize, with Dr. Dale, that both qualities were possessed by Paul Ehrlich. There are signs already that his very clear-cut chemical conceptions will not, in the form in which he put them forward, prove finally adequate; but his is the credit of a bold attack on the problem. The task Ehrlich set himself was to find for each type of infection a substance with a powerful chemical affinity (and therefore a strongly poisonous action) for a particular parasite, and at the same time with a relatively small chemical affinity (and therefore very little poisonous action) upon the organs and tissues of the patient.

Among the most recent curative substances obtained by this line of investigation is the new remedy produced by the German chemical firm of Bayer, and known as yet simply as "205." It would seem, as Dr. Dale pointed out, to be a remarkably curative agent in trypanosome infections. An advanced case of sleeping sickness in a man was sent from the Liverpool School of Tropical Medicine to be treated in Hamburg (because the drug was not allowed to be exported from Germany), and after two injections the patient was, within a few weeks, spending his convalescence in a walking tour in the Black Forest, and by all accounts has gone back to Africa a new man. A commission of German doctors, with the permission of the Colonial Office, has gone to Rhodesia to put the new remedy to a thorough test; the preparation has now been made available in this country, and is being tried at the London School of Tropical Medicine. The drawback to this promising remedy for human trypanosomiasis is that it has an energetic effect on the kidneys; it is too soon yet to say whether the damage is permanent, but there cannot be much doubt as to the choice between death from sleeping sickness and life with some renal impairment. The substance, it seems, is not a dye, like trypan-red and trypan-blue; when applied to the trypanosomes outside the body it does not appear to check their vitality, though the evidence on that point is incomplete. Dr. Dale suggested that when the constitution of this substance is revealed by the manufacturers it may provide the basis for a new conception of therapeutic processes, and perhaps the point of departure for progress towards yet greater success.

Dr. Dale dealt also with the organic compounds containing arsenic. It is, he thinks, clear that salvarsan does not by itself directly kill the spirochæte: the body of the patient must in some way co-operate. The success of arsenical compounds naturally suggested the trial of substances containing the closely related antimony, and the old familiar tartar emetic (tartrate of antimony and potassium) has proved to be a remedy in its province quite as specific as salvarsan. Dr. Christopherson in Egypt conceived the idea that if tartar emetic was of use in kala-azar (as it certainly is), there was no reason why it should not be tried in bilharziasis. He found that its introduction caused not only the death of the trematode worms in the veins of the bladder and bowel which caused the infection, but also the destruction of the eggs and their irritating and penetrating properties. With Dr. Leiper's work in the field of prevention and this method of cure, the complete extinction of this serious and disabling disease may, Dr. Dale thinks, be predicted.

Another method of treatment to be mentioned in illustration of the subject is the use of emetine. When amoebic dysentery became rife in the army during the war the knowledge then available suggested that the action of emetine as a cure for dysentery was the one clear example, among many to the contrary, of the direct killing of the parasite which caused the disease. When, however, Dr. Dale came to study the matter with Mr. Clifford Dobell, and particularly when amoebae were taken perfectly fresh and vigorous directly from dysenteric ulcers in the bowel, it was found that the chief alkaloids of ipocacuanha (of which emetine is one and cephaeline another) had a surprisingly weak action on the amoebae. Really vigorous amoebae could be kept crawling about for two hours in a solution of emetine hydrochloride as strong as 1 per cent. Certain artificial derivatives were then made, including methyl-emetine, dimethoxy-emetine, and iso-emetine; the second of these was found to be ten times as poisonous for the amoebae and not nearly as poisonous for the animal as the natural product, but it had no therapeutic effect whatever. This, therefore, was the surprising result: that the curative action of these alkaloids was proportional, not to their poisonous action directly on the amoebae, but to their poisonous action on the patient: the body of the patient must play an essential and perhaps a primary part in the killing of the parasite.

Such facts as these afford some idea of the complexities with which the investigation of remedies is beset. In the production of a curative effect the body of the patient in all these cases plays a part which is not yet fully apprehended. The nature of the co-operation between the remedial agent and the living tissues is hard to unravel. But work in this direction is an essential step towards a further theoretical basis for rational, orderly, and steady progress in therapeutic investigation. The importance of such advance for the future of mankind is incalculable.

THE HIPPOCRATIC OATH.

THE formula which goes by the name of the Hippocratic Oath has come down from the fourth century B.C., and appears to have been the promise given by those who were accepted as students of the medical art by the Asclepiad Guilds of Ancient Greece. Its authorship is generally attributed to the physician Hippocrates, who, to distinguish him from others of the same name, is often called "Hippocrates the Great," and who lived approximately from 460 to 380 B.C. Sprengel and others have, however, contended that it emanated from the medical school of Alexandria. Whether Hippocrates actually composed it or not, the oath was at all events associated with the venerable traditions of his name through the classic and mediaeval periods of medical history. Even the medical writers of the first century—for instance, Erotian, who lived at Rome in the reign of Nero, and Scribonius Largus, who accompanied the expedition of the Emperor Claudius to Britain in 43 A.D.—refer to it in terms of the highest respect, and attribute it to Hippocrates. Since their time it has formed the general guide in ethical matters for practitioners; and numerous variations, which plainly show their derivation, have been used by the older medical schools as the *sponsio academica* exacted from graduates at the time they received the right to practise medicine.

The oath, as translated by Francis Adams (1849), runs as follows: "I swear by Apollo the physician and Aesculapius, and Health, and All-heal, and all the gods and goddesses, that, according to my ability and judgement, I will keep this Oath and this stipulation—to

reckon him who taught me this Art equally dear to me as my parents, to share my substance with him, and relieve his necessities if required; to look upon his offspring in the same footing as my own brothers, and to teach them this art, if they shall wish to learn it, without fee or stipulation; and that by precept, lecture, and every other mode of instruction, I will impart a knowledge of the Art to my own sons, and those of my teachers; and to disciples bound by a stipulation and oath according to the law of medicine, but to none others. I will follow that system of regimen which, according to my ability and judgement, I consider for the benefit of my patients, and abstain from whatever is deleterious and mischievous. I will give no deadly medicine to any one if asked, nor suggest any such counsel; and in like manner I will not give to a woman a pessary to produce abortion. With purity and with holiness I will pass my life and practise my Art. I will not cut persons labouring under the stone, but will leave this to be done by men who are practitioners of this work. Into whatever houses I enter, I will go into them for the benefit of the sick, and will abstain from every voluntary act of mischief and corruption; and further, from the seduction of females or males, of freemen and slaves. Whatever, in connexion with my professional practice or not in connexion with it, I see or hear, in the life of men, which ought not to be spoken of abroad, I will not divulge, as reckoning that all such should be kept secret. While I continue to keep this Oath unviolated, may it be granted to me to enjoy life and the practice of the art, respected by all men in all times! But should I trespass and violate this Oath, may the reverse be my lot!"

Some of its provisions have, with the changing outlook and habits of modern times, become as obsolete as the invocation of Apollo and Aesculapius with which it opens. Others, which inculcate generous and honourable conduct, remain as applicable to-day as they were in the age of Pericles. Among the latter, the provision regarding professional secrecy has been sometimes quoted recently, and is worthy of examination. It is evident that the deviser of this oath did not intend to lay upon his disciples an absolute prohibition against revealing things that they might see or hear in the course of practice. The words, which are translated "things which ought not to be spoken of abroad I will not divulge," clearly indicate a prohibition to the practitioner against making the affairs of his patients matters for idle gossip in the streets and market-place. There could have been no intention in the mind of Hippocrates to debar his followers from bringing professional matters into the law courts or otherwise revealing them for the public welfare. The meaning of this passage becomes even clearer in view of the fact that in several of the ancient MSS. of the Oath the word *ἐκκαλέσθαι* (divulge) is replaced by the reading *ἐκκαλέσθαι* (babble about).

It is interesting to consider to what extent the old tradition of a Hippocratic oath is preserved by the great medical schools of England, Scotland, and Ireland. The Universities of Oxford, Cambridge, London, Leeds, Belfast, and Dublin exact no declaration of this nature from those on whom they confer degrees. At Durham, Manchester, and Liverpool there is no declaration by medical graduates, but dental students give a promise not to advertise. At Birmingham the graduate undertakes to uphold the honour of the University; and those who obtain the Conjoint or Triple Qualification from the various Royal Colleges give a similar undertaking to their respective Colleges along with a general promise of honourable professional conduct.

In the four Scottish Universities only is the Hippocratic traditional formula preserved. At Aberdeen it is very briefly summarized by an Obligation, taken at

graduation, from which, however, the question of professional secrecy is omitted. At St. Andrews the formula closely follows the original Hippocratic oath, but, in the clause regarding secrecy, the wording runs: "Whatever during my attendance I may have seen or heard, which it would be inexpedient to divulge, I will keep silence regarding it." At Glasgow there is a declaration summarizing the oath, and the clause on secrecy runs: "I will keep silence as to anything I have seen or heard while visiting the sick which it would be improper to divulge." Edinburgh alone preserves still an old-time Latin formula by which the graduate promises that he will not make public without due cause matters that he may have seen or heard in practice.

It appears, therefore, that most of the universities and other licensing bodies of Great Britain and Ireland have long regarded the question of professional secrecy as a matter outside their concern, while in the few which still exact from the graduate a promise in regard to it the duty of secrecy may in any case be abrogated by expediency, propriety, or sufficient reason.
